Presidential Address

ON
**THE UNIVERSITIES IN MEDICAL RESEARCH
AND PRACTICE.**

*Delivered before the Eighty-eighth Annual Meeting of the
British Medical Association in Cambridge*

BY SIR T. CLIFFORD ALLBUTT, K.C.B., LL.D.,
M.D., F.R.S.,

REGIUS PROFESSOR OF PHYSIC, UNIVERSITY OF CAMBRIDGE.

[Sir Clifford Allbutt began his address with a vivid review of the social and artistic development of England when the claims for continental dominion were relinquished, in the course of which he showed that the older Universities, at home and abroad, were not "founded" as such, or as we know them, but grew with the needs of the age.]

THE UNIVERSITIES AND THE PROFESSIONS.

He proceeded to show that the Universities, ancient and modern, have made the professions by the fostering of research and the maintenance of due standards. Instancing Greek and Roman examples, he insisted that no particular calling can be followed without an education which connotes a more comprehensive design. "We are teaching Medicine well; but we need badly a *common literary basis*." Regarding education from the first as an introduction to life, he pointed out alike the danger of specialisation and cramming. He insisted on the need, met at Cambridge to some extent by inheritance from forefathers, of imagination in the pursuit of learning, and recommended the simplification of the necessary years of pupillage in medicine—"five years is long enough in all conscience for a young man to spend in learning to be a safe practitioner"—by the recognition of one curriculum for a diploma, and another, of extended form, for the University degree. The candidates for the diploma—and he favoured a one-portal system—would put immediate utility in the first line, while each University would be left free "to mould its teaching after its own fashion and standards, and to transform its interior tests." He concluded this section of his address by affirming that the medical curriculum could be substantially lightened by better teaching, and described the structure and aims of the educational course for medical students at Cambridge. He continued:—]

THE DEBT OF OTHER SCIENCES TO MEDICINE.

My old medical friend, Mr. Meade, of Bradford, was almost the only man who knew much about flies at the time when Manson and Ross began to watch these little pests. Without Medicine bacteriology, and the study of the cell, would have made slow way; yet it is the study of the cells of bacteria, of algæ, of protozoa—not of mandarins—which has brought us nearer to the secret of life. On the wonderful world of the cell I have spoken before. Professor Hopkins has lately described to us the almost incredible coexistence in it of different constitutions, phases, and events; though every change in any phase affects the equilibrium of the whole cell system. And every one of these is essential to the whole; "so long, for example, as a liver cell remains alive its glycogen constituent cannot be wholly removed." If a cell be so ground up as to become more homogeneous, its reactions fall out at haphazard, and the cell dies by mutual destruction of its parts. This process of nature is illustrated on a mighty scale to-day in the disintegration of the Russian social organism.

Some of the apparently simple cell constituents, hæmoglobin, for instance, are incredibly complex; this substance is specific for every kind of animal; in allied species, if concordant, it is not identical. Of the chromosomes I need say nothing, except to hope that as X rays have analysed crystalline structure some such rays may analyse nuclear constitutions.

No. 5053

By another way Medicine has promoted research on organic syntheses; and conversely on the reduction of foods into the more complex amino-acids before being re woven into the tissues of life. From Medicine began our recognition of the plowman as the first parent of animals and man, and our fuller knowledge of "the green plant as the fundamental capitalist."

Herbs gladly cure our flesh, because that they
Find their acquaintance there.

In the dark soil the nitrifying bacteria live on inorganic matter; so in the light some inorganic colloidal systems can build up formaldehyde (B. Moore). Medicine has introduced the chemist to the domain of the hormones and chalone, themselves also bodies of the simpler chemical constitution—some crystallisable, all able to resist prolonged boiling—blended into a wonderful physico-chemical coördinating system, secretly at work all the time under the diagrams of the innocent neurologist. We may suppose, indeed, that every active tissue of the body, or every cell, even of bone and skin, or of the substrate of mind itself, like every individual of a social organism, contributes some element to the organic whole, some inward production necessary for growths or for signals.¹ There may be a world of pathological (alien or perverted) hormones as yet unexplored. May the dive inwards of epithelial cells in cancer be due to some inversion of chemotaxis, possibly under the influence of an alien (parasitic?) enzyme? Within the body, then, all parts are the "environment" of each—so that we have both an inner and an outer "climate," an aspect of the microcosm not to be forgotten in the field of mental disease. Thus it is that "Each part may call the farthest, brother." And these agents have a field of action far beyond the body, as we see, for example, in the sexual hormones. If there be a "migration hormone" its sphere is the world.

Again, is it not largely by Medicine that the study of enzymes has thrown light upon the operations of catalysis which, like the rollers under a log or, as we now think, more by engagement and disengagement like rack and pinion, is incessantly forwarding by various intermediate series and by reversible actions at points of concentrative equilibrium the processes of nature? The vitamins may be of this kind, agents which have upset our cruder calculations of nutritive values; for instance, in the feeding of children we no longer take cane sugar to be the vital equivalent of lactose, nor margarine of butter; not all the nitrogen of nutrition is included in protein, nor are phospho- and amino-lipins, nucleic acid, amino-acids, and so on, mutually convertible in the body. We must admit that the fundamental principles of nutrition have yet to be redetermined. Moreover, the war has forced us to remember the mutual dependence of food kinds; that of course fats and carbohydrates are not wholly independent or equivalent; the carbohydrates cannot make up any great lack of fats, nor can oxidation of fats proceed in the absence of carbohydrates.

Another system of balances in the body, as of the reciprocal functions of lung and kidney, is more obviously chemical. Medicine has taught us how the lung deals with the CO₂ ions, the kidneys with sundry other acids, so that the blood reaction is maintained with extreme nicety; and that other systems—for example, the vasomotor—are probably little less sensitive, and that there are other subtle causes of anoxæmia besides the cardio-pulmonary (Haldane); so that in Medicine it is of the first importance that in all abnormal conditions the oxygen tension of bloods should be systematically ascertained and compared. The hydrogen-ion concentration is consistently higher upon flesh diet, lower upon vegetable diet; but, I think, we have not yet learned to discriminate so subtly as Charles Kean, who is said to have chosen his viands according to the parts he had to play—pork for tyrants, beef for murderers, mutton for lovers.

Next after the origin of life itself, from ancient times to this day no enigma has attracted and baffled the curious mind of man more than that of living "form."

¹ Mathews: *Physiological Chemistry*, second edition, p. 835.

Many of our keenest minds—Haldane, D'Arcy Thompson, Osborn, Dendy, McBride, I mention a few names as they occur to me—are still chasing this will-o'-the-wisp; and moth-like I cannot but flutter after them. Of the nitrifying bacteria which assimilate inorganic matter, of the synthetic amines of animal nutrition, of the properties of colloids, I have spoken already to-day and last year; but "how," says Dr. Haldane, "is constant form maintained amid the continuous changes of our changing matter?" and—I may add—of variations of parts. Is "form" something after the manner of a seal, which is impressed upon matter? or is it, in Aristotle's sense, a kind of soul (*entelechy*) which shapes the potential, or capacity, into integral being? Here we hover between metaphysical or ontological concepts and natural law, or the properties of matter. A few years ago all notion of self-shaping was dismissed, and the animal regarded merely as a diagram of incident forces; to-day there is some harkback, if not to moulding entities, at any rate to some phases which partake both of germ and matrix. We had been taught that for development functional stimuli were all that was necessary; for instance, that the heart grew, even beyond the normal, only in response to demand for its work and by increased supply of blood to its tissues. But is there any functional adaptation from within? If a limb be not used the bone will still grow more or less; but why does the bone grow *round*? And an eye will grow, from a germ of it, in the dark (Loeb). Is there such a property in living matter as "functional adaptation"? Is function in its effect upon form adaptive or purposive? Is environment met by adaptive variation—for instance, in a germ cell? Again, if so, can specific properties of such a kind be acquired? Biologists seem to have proved that evolution of form may go on continuously when environmental change is suspended, or remains constant; and conversely that environmental change does not necessarily induce evolution. On a broad view, says Professor Osborn,² during the infinite variety of the widely diverging forms of the Mammalian period of the earth, the reptiles have shown very little change. We perceive that these questions arise in some contrast with the hypothesis of the selection of "chance" variations.

On the other hand, we find reason to marvel at the constancy of bacterial species; humble and embryonic beings that we should not expect to have become fixed in their habits. Yet they and their enzymes are very exacting about it; as we find, for example, with the several enteric bacteria or with the meningococcus or pneumococcus varieties, of which each has its own serous or agglutinin test, and is indifferent to the rest. And there is more still to be said; when the microbe finds itself in the host's body it may be wholly out of tune, or wholly in tune, with any or all cells that it approaches; in either case presumably nothing morbid would happen, perhaps, by a kind of zygosis, a benefit; morbid happenings would lie between this microbe and body cells within its range but not in tune with it. Now there seems to be reason to suppose that a microbe, on its approach to a body cell only just out of its range, may try this way and that to get a hitch on. If so, the microbe, at first innocuous, would become noxious. So on the other hand body cells may educate themselves to vibrate in harmony with a microbe before dissonant; or there may be mutual interchange and coadaptation. Such considerations arise out of many known phenomena at phase boundaries, of sympathetic vibrations, of acquired immunity, of new virulences, and so forth; the cells out of tune getting nearer and nearer into consonance with each other.

But, if things be so, surely we are face to face with a marvellous and far-reaching faculty, *the faculty of choice*, and this rising from the utter bottom of biology to the summit—formative faculty—"auto-determination," or, if you please, "mind." Can the microbe do as the retriever does when with a hare in his mouth he comes to a gate; he tries this way and that, then thrusts the hare under the gate, leaps over and pulls the hare through? So the microbe tries it on, this way

or that, till it succeeds, by self-education in the school of experience—*Bildungstrieb*. This is far more—radically more—than "*élan vital*"; not merely energy but *choice*—plasticity driven to choose or fail; thus new devices are tried and new habits established. So likewise Dr. Topley has dwelt upon a microbe acquiring a capacity to bring about certain fermentations,³ an ability, as he says, "to be regarded as something inherent in the organism itself." We may be reminded also of Professor Stanley Gardiner's "education" of his oysters—a very curious observation.

So far as I can think upon it there seems to be but one alternative hypothesis, but this does not cover so many phenomena. As I have said, if the vibrations of an alien cell are out of range of a certain body cell so as just to be indifferent but yet not far out of range, the vibrations of the one might induce like vibrations in the other, and meanwhile interference waves would arise in the field; thus disturbances—symptoms—would begin and continue until the two sets of waves should blend into unison; and this would mean acquired immunity. If a number of wag-at-the-wall clocks are hung near each other, in a calculable time they will get to swing in unison. But this hypothesis does not lead on, as does the trial and error hypothesis, to larger and larger gains. We see only a discord and a mode of requiescence; no line of development. What we apprehend is something more than orderliness of chemical reaction; that *cells are teachable*; a key to illimitable progress. Was not Coleridge right when he said—

"For I had found
That outward forms, the loftiest, still receive
Their final influence from the Life within."

I am not for one moment forgetting that the physical modes of energy—adsorption, surface tension, and so forth—may count for much in these advances, arrests, immunities, and disintegrations. Adsorption, or other physical condition, may put up a block. How remarkable are the effects of anaesthesia and palsy which may follow injections of sodium oxalate and magnesium sulphate, and of their quick removal by calcium salts; indeed, the whole influence of calcium on metabolism—probably all of them surface (interface) actions, as of any radio-active element upon cell function.⁴ Indeed, as in the relation of foodstuffs to amines, so in the physics of the cell we may discover a comparative accessibility and intelligibility of the processes of life—Poincaré's "*simplicité cachée*." It seems that God has more "respect to the measure and ease of the human understanding" than Boyle supposed.

RESEARCH.

Thus we are led to the thaumaturgic word "Research" which, for some of us, means remote and rather unreal speculations; for others the discovery of short cuts to making more money; for others again the ideal of pure knowledge. Research may be regarded as of two kinds, as natural observation and as artificial experiment; the one yielding more and more to the other as investigation penetrates from the more superficial to the deeper processes. Still, if we are to surprise and "capture wild nature in her secret paths," the two ways are strictly inseparable. Indeed, the infinitely little does man more harm than the enormously great. War may bring with it some redemptive virtues; pestilence only raw superstitions. The advance of the last half century from the deadhouse pathology to more refined and penetrating methods we have witnessed in our time, and yet more intimate methods, those of biochemistry for instance, are being rapidly unfolded. Research, as it is working to-day, advances from fixed and measured bases; as observation it watches Nature's march past; then as experiment it puts events to test under artificial conditions of separation or isolation, and measures their phases. But the laboratory cannot, as Nature does, contrive the unexpected; so we must "gear up our tiny machines to the vast wheel of Nature," and try for a first roughing out of an idea or concept. If we are to select our facts

³ THE LANCET, May 22nd, 1920, where he quotes "Penfold and others."

² Osborn: *Origin and Evolutions of Life*, p. 137.

to any considerable purpose as crucial, we must first have an idea in our minds; and for this a certain kind of imagination is needed, one of general concepts rather than of the concrete individualising imagination of the artist. Thus there are two kinds of discoverers, whose comparative outlines we have not yet well discerned. Of scientific discovery Henri Poincaré gives an interesting appreciation; he says that discovery consists of three stages: the first stage is of laborious work at the problem on all sides; the next is not one of conscious occupation with the subject, but of unconscious cerebration, during which a promising hypothesis may unexpectedly arise in the mind; the third is deliberate verification and completion of form. Thus out of an unlimited number of possible combinations, and by many speculations, the discoverer at length divines the true one. In Medicine this has been clearly the course of surgery, the side of Medicine which is closer to nature.⁵ The surgery of my young days was only too "observational"; the friendly fingers of curious colleagues were popped in and out of an operative incision with no apprehensions about "the infinitely little." Now the observer is sadly pushed aside; the ritual of surgery is become like the magic rites of old, of which, if a point were dropped or a word changed, the virtue went out. But the rite could be done over again by the penitent; unluckily in surgical rites there is little room for repentances.

A new scheme of research into the origin of diseases, lately instituted at St. Andrews, claims our respectful attention. And may I be forgiven if here I pay a tribute to the rare devotion which inspired Sir James Mackenzie to forsake place and honour to follow after knowledge; indifferent whither he were led so long as truth was the leader. Sir James Mackenzie argues that the man in charge of the first deviations from health is the general practitioner; and that, if we are to detect diseases in their incipience, he must be the detective. One evening about the year 1879, when staying with Sir George Humphry, he and I sat into the small hours devising a method by which we hoped to engage the general practitioner in scientific investigation. We secured the coöperation of this Association and of many coadjutors⁶; Dr. Mahomed joined us as secretary. We hoped by gathering in large numbers of observations to eliminate error; and several series of questionnaires were distributed. Four volumes of reports were issued, under such editors as Humphry himself (on Old Age), Butlin (on Cancer), Whipham (on Rheumatic Fever), and Isambard Owen (on Intemperance). But the effort was premature; the data were too rickety, the reports too often irregular, dilatory, and imperfect, and the reporters untrained in observation, punctuality, and precision. As things are few of our colleagues remember to let us know the issues of cases seen in consultation. We may hope now for better material and more accurate workers; not only so, but Sir James Mackenzie is developing another and no doubt better method—he is working with intense culture on a small holding and on a more intimate clinical plan.

In exploring a country the great watersheds and rivers are first laid down; to map out these and their valleys and tributaries is the first great work. These main features known, bearings are obtained whence to discover the contours of the hills and to track up to the hidden sources of the streams. This is Sir James Mackenzie's mission—to track out the nascent rivulets, and with his divining rod to dig for the springs which feed the streams of disease.

Let us not suppose that this research will be but a matter of cleverness, sagacity, or even of intensive observation; nor flatter ourselves that because Mackenzie produced his great work on the Pulse while a general practitioner that he achieved this by ordinary clinical observation, however acute. The progress of Medicine must in large part be endogenous. While our pathologists in balloons were working on morbid phenomena without ever seeing a sick man, Mackenzie was bringing laboratory equip-

ment and exquisite laboratory methods to the bedside. The polygraph, no easy instrument to handle even now, was the grandchild of the kymograph; and by it was proved again that science consists—as Plato said five centuries before Christ—in measurement. So in the St. Andrews research, not only have the initial warpings to be discovered, in their many ways and tides, but their volumes and their curves also to be measured as precisely as were those of the circulation by the polygraph. The physicist and the biochemist will need all their expertness in valuing molecular motions, analysing secretions, recording blood tests and morphologies, and so forth in their earliest and subtlest phases. For it is in molecular dynamics that the first deviations will arise; massive visible changes come later, and happily are now in large part calculated or calculable. Mere observation—Nature's march-past—will not count for much now; and as to family histories—well, they vary with each historian. And we practitioners will need a more searching discipline before we can occupy ourselves with problems so subtle.

The laws of inheritance must, I think, be sought out, at any rate at first on animals; the generations of Man are too long for comprehension; besides, something else seems lacking in this study of the Genetics of Man? Is it a sense of humour?

COMPARATIVE PATHOLOGY.

And there is something more to be said. If light is to be thrown upon the generation of diseases in man it must be in part also by study in a far larger field we must discover and compare the elements and phases of disease in animals and in plants. Sir James Paget, in his admirable address to the Pathological Section of this Association at Cambridge in 1880, reflected on the difficulties of human pathology because of its great complexity. He had "long and often felt that in this difficulty we might gain help from studying the consequences of injury and disease in the structure of plants" as less complex and under simpler conditions. To this field of pathology he devoted almost the whole of the address. A large part of my address in Medicine to this Association in Glasgow in 1888 was given to this appeal; it has found no response, hardly an echo. Yet what would anatomy be without comparative anatomy, language without comparative philology, anthropology, law, history, and even religion without a like comprehension? Without an Institute of Comparative Pathology in Cambridge our range of vision and work is contracted. In the "field laboratories," it is true, Professors Woodhead and Nuttall, ably seconded by Dr. Stanley Griffith, are doing as much as lies in the power of a few individuals; but any such effort is puny beside the sphere of observation and research awaiting us. The comparative survey must cover the diseases of plants as well as of animals, of the lowest of living things up to the highest. The money loss year after year caused by the depredations and the diseases of animals and plants is enormous, and many of the methods of dealing with them—as with foot and mouth disease and swine fever—barbarous, if at present imperative.

Yet no one stirs, save to gyrate each in his own little circle. There is no integration, no organisation of research, no cross light from school to school, no mutual enlightenment among investigators, no big outlook. The destruction by insects in forestry and agriculture alone in Great Britain is put at £30,000,000 per annum.⁷ An Institute of Comparative Pathology in Cambridge, with the endowment of professorial chairs and subordinate workers, would cost, no doubt, a quarter of a million, a big sum; but what is this to the wastage of disease throughout the world of life!—to swine fever, diseases of cattle and horses, of crops, of forests, and so forth—utilitarian ends it is true, but to be followed on paths of discovery which would illuminate the whole field of nosology. Diseases are not "entities," nor even recurrent phases of independent events, but partial aspects of a universal series. The young graduates we have, many of them of great capacity; but every day we are losing them because they are not taken up at once into scientific teams; so they slacken, or drift into

⁵ See C. A., Hist. Relations of Medicine and Surgery.

⁶ See Sir G. Humphry's Presidential Address at Cambridge, 1880.

⁷ Mr. L. Scott, M.P., in the House of Commons.

some other means of livelihood, and things muddle on as before. How blind we are!

PSYCHOTHERAPY.

[Here Sir Clifford Allbutt reviewed with force and pungency the modern developments of psychotherapy, for, "of late, their pursuit has stirred up much, and once more the human heart is declared to be a very messy place." With shrewd criticism of a certain side of psychoanalysis, he admitted the power, for good and evil, of suggestion in the life of a social animal, and the value of modern clinical research into the psychic complement of structural diseases.]

The moral on the whole is, he said, that we must use much circumspection in straying beyond the strand of experimental psychology—a fruitful inquiry so long as pursued on the methods of science. I do not say that in its applications to the many and variable callings and stresses of life, there is no place for psychic empiricism, no place for prying beyond the margins of evidence; but the surer must be our footing on the known, and the closer our watch upon our terms. Not for one moment do I forget the admirable work done in psychology in our own laboratories, at Oxford, and in the great pathological schools of the Maudsley, and the London Hospitals, and elsewhere. And the methods of the Industrial Fatigue Research Board, for the study by "vocation tests" of the "psychological relations between management and labour," seem to me, if I may say so, to be on sound lines, and to be likely to shed light upon the economy of both mental and bodily work. Again, such researches as those of Dr. Scripture on the speech of epileptics, whether verified or not, are at least conceived on sound lines of scientific method.

The black fate which befell the insane, once so humanely, rationally, and happily treated by the ancient Greek peoples from Empedocles to Galen or later, is one of the monstrous depravities which befoul the history of man; centuries of cruelty which lasted down to our own times.⁸ When a Commissioner in Lunacy I did my best, encouraged by the late Dr. Hack Tuke, to convert the plans of new asylums from the barrack system to a village system; but every such attempt was thwarted by a stolid, idealess body, the Local Government Board of that day. A village community, with its homely associations, its groups of cottages, hospital, park, gardens, home farm and workshops, church, town hall and theatre, and its various social scenes and interests, would provide for nervous disorders of all kinds, and so lighten the shadow of insanity. Patients could be moved within the groups from one section to another without formal inquisition; with no more ceremony than precise entries in the case-books open to the Visiting Justices. In the treatment of any case of mental disorder the physician may soon, and often suddenly, be faced with the necessity of bodily restraint; and I cannot satisfy myself that patients should become liable to mechanical restraint or to confinement without the strictest precautions and guarantees. At Whitehall we were never without some information, only too often true, of concealment of insane persons, and of their ill-treatment in the sense of cruelty, or of bonds, or of coercion, or of neglect of proper domestic or medical care. The present obstacles to early treatment, it is true, are a grave hindrance to successful therapeutics, but the legal and practical problem is more intricate than public opinion is aware of.

GENERAL PRACTICE.

When I turn to Public Medicine I am met by two chief problems that call instantly for solution. If by studying the past we can better build up the future, what will history tell us of the future of the "General Practice" of medicine; and what of the Voluntary Hospital? He is a bold man who will pretend to foresee even the near future of either; yet neither can stand where it is at present. Let us consider General Practice first.

In England we cling to concrete experience; we look for friction, unexpected turns, compromises, chances; we have little belief in systems of thought and dialectics, and in medicine, as in political and social affairs, have

trusted to experiment, to touch; we find safety not in ideal revolutions, nor in rigid organisation, but in broadening down, in criticism, and in the fertility of intuitive action. Scientific therapeutics are not to cast out empirical methods. The compass of large principles is often too wide for daily needs. We want theories within theories, axioms of less scope but more readily adaptable to the wantonness of life. Very true; but also the craftsman must bow his head to the deeper and wider principles which will eliminate the essentials and economise the direction of his work. If the family physician must be rather receptive than productive, by the diffusion of scientific knowledge, and increasing familiarity with the spirit of science, the climate of thought will be changed throughout the profession.

The better class of general practitioner of 50 years ago was rather after the kind of Hippocrates or of Paré than of the modern graduate. His university, in the days before great cities—the "great wens" of Cobbett—was nature; in his clinical experience he enriched the instruction, half empirical, half dogmatic, of his medical school by the shrewd, observant, self-reliant, resourceful qualities of the naturalist. His science and his practice were of the naturalist, not of the biologist. In my early days a country drive with such a doctor in Yorkshire used to be one of the rewards of the consultant; and a bedside talk with him a lesson in quickness of wit and hand, and of instructive inference and prognosis. He was as clever as the modern cardiologist in knowing when to give digitalis, when to withhold it; if he were content to diagnose a case as "some bedevilment of the liver," his rules of thumb were not without their efficacy, and his *flair* for the issues of disease marvellous. He did not come across much "science," and what he did see of it, chiefly in casual "locums," did not attract him; for in truth half-science was less useful to him than whole craftsmanship. He was a woodland guide, not a geographer; but, as Aristotle and Darwin well knew, the woodlander gathers much curious lore. However, in the march of intellect this comrade, kindly and loyal as he was, is gone; and his sort of wisdom dies with the individual. Who is to come next? The official doctor, or a family physician more intellectual and no less independent?

An official doctor would be as alert and as progressive as a country parson, whose service is not much kindled by the chances of promotion to an archdeaconry or a bishopric; while to shift an official doctor from place to place would be to cut the inner threads of those intimacies which we are now declaring to be clues to the detection of diseases at their sources. Yet, as things are, the independent practitioner is isolated; even in a town he is apt to make a little orbit for himself, to drift out of intimacy, perhaps into some jealousies, with his brethren; he lacks mental incentive, and gradually lets slip occasions of scientific reunion and renewal. Indeed, he cannot readily leave home to attend public and scientific meetings, so that too often—as Morant complained—"medical men do not think nor express themselves in a statesmanlike way." His time even at home is so broken up that he loses the habit of study. He may leave his hospital school full of ardour and in rapid growth, but in practice his ardour cools and he drops into routine; or, at any rate, such is his peril, and so less and less may the doctor feel himself a member of a great profession; he may drift out of public affairs, his outlook and sympathies may shrink, his work become a trade, and his medical neighbour his "opponent."

Again, for some years past a few of us have been protesting against the clipping of family practice by official shears. We see the subjects of infectious fevers carried into isolation, and the tuberculous and syphilitic disappearing with them. The children are turned over to the school doctor, the parturient woman to the new midwife, and so forth. What is to be the end of this pollarding of family practice? Are its branches to be scattered about in a wilderness of "specialists" and the family physician a mere sweeper up of unconsidered trifles?

Panel practice, for some time discredited by its hereditary taint of the Club of infamous memory, and

⁸ Pinel d. 1826; Schröder v. d. Kolk d. 1862; Conolly d. 1866.

by the continual dearth of the means of its development, should, if duly provided, expand into a large, honourable, and even universal department of medical work. The terms of engagement are to be more liberal; the clockwork is complete. But how is the practitioner to rise to higher standards of modern science and skill when no means of investigating disease or of making an intimate diagnosis are provided for him? He is well aware that the modern methods of medicine depend on such means as X rays, a battery of stains, and other cultural and biochemical apparatus; and not only an education in the use of these, but also the time to give to them. What should we think of a regiment of recruits called out to fight the enemy but unprovided with weapons or munitions? If the doctor be near a university centre he can get blood tested for morphological elements, or for sugar or nitrogen content, excretions analysed, bacterial examinations and vaccines made, and so forth; but it is imperative that these opportunities, now confined to a few, shall be universal. Moreover, if they are to be fruitful, the practitioner must consult personally with the scientist. These plants, then, and their staff must be established in all districts, together with a much larger provision of cottage hospitals. This university and its sisters are sending out every year bands of young graduates quite competent to deal with disease in all its forms, and to use refined means of diagnosis if these means are supplied. If not, how can we blame them if they fall into some stagnant routine? In district laboratories panel work would be paid by the Ministry of Health; for private practice a tariff of fees would be agreed upon.⁹ A considerable sum for the commencement of these local centres was contained in the still-born Budget of 1914.

In the United States I am told that medical men are banding together in districts for such a development of their private practices. Five or six of them combine to rent a house with consulting rooms for each, and a common apartment for minor surgery, &c. Each member of the alliance—they are not exactly partners—is expected, in addition to his general practice, to take up special work in some department supplementary to the others; so that a fair variety of special skill may be available in the house; skill, if not of high expert value, which must still be sought elsewhere, yet quite sufficient for ordinary diagnosis and treatment. For this purpose visits of members to special clinics and ordinary holidays are mutually arranged. Patients like the system; they see that it is more thorough. Domiciliary visits become fewer, yet there is always one of the group on the spot. The fees are received by a secretary-attendant on the separate account of each member, and after all upkeep expenses are met the surplus is divided according to the credits of each. The individual earnings are higher than they were on the separate practices. Such are some of the material advantages; the spiritual are the disappearance of petty jealousies in a spirit of comradeship and a larger freedom for scientific and social life and for public service. The patients learn that a due remuneration of medical service is no longer gained by a multiplication of visits, nor by profits of dispensing.

These ends may no doubt be attained by different methods, but the essential need is the generally accessible laboratory and staff to be a little academy and place of reunion—a centre, let us say, for the meeting of the Divisions of this Association. But one word of caution: this centre must not be municipal, it must be free of all kinds of officialism, and kept alive by a small committee of local practitioners in alliance with the Insurance Commission.¹⁰

As regards the Voluntary Hospitals, I omit what I had written because the Report of the Consultative Council has covered a much larger ground, and so ably, that my

passing reflections would be of little use. The dilemma between the lack of funds and the fear, almost an assurance, that public grants in aid would discourage private munificence, might, I think, be avoided if, on proof of efficiency, grants in aid were offered in some proportion to the amount raised by voluntary effort. To range up the Poor-law infirmaries with other hospitals and schools would enrich our clinical fields beyond all anticipation.

PREVENTIVE MEDICINE AND CLINICAL PRACTICE.

On the social mission of Public or Preventive Medicine, and on its integration with clinical practice, Sir George Newman and others of our leaders have said what is needful, better than I could say it. It is strange that not until the other day—so to speak—has the public awakened to its own needs in this matter, seeing that, at least from the seventh century before Christ and onwards, public health officers were appointed in the Greek countries. Yet 25 centuries later my old friend Dr. Warburton, of Pateley, wore out his life, and much of a good practice, by his not unsuccessful fight against enteric fever in the valley of the Nidd; and, thank God, he was but one devoted warrior among many. Let us remember, however, that the public has neglected science partly because science has neglected it. Now the medical service of the Panama Canal, and of the Great War,¹¹ by specific immunisation, brilliant sanitation, and modern methods such as the isolation of carriers, has brought medicine home not to each nation only, but to all men as an international and reforming influence. Of late years surgery has made our advances conspicuous, but inner medicine is coming again into her own; nay, they are one. From lesser to larger groups the standard of health must be more and more the guide and the signal of the nation, of the country, of the city, of the workshop; for public health is purchasable. If, by his invention of tools, Man has become the destroyer of creation, let Medicine show that tools can also be its saviour. Every righteous physician regards his practice as a social service, a means not only of bodily but also of social reconstruction, and of moral and intellectual health. Thus Medicine will become more and more a binding force in societies, a bond between nations, and a purification of the world.

Clinical Lecture

ON

FIBROIDS, LIPOMAS, DERMoids, AND POLYPI OF THE STOMACH AND INTESTINE.

Delivered at the Middlesex Hospital on April 22nd, 1920,

By SIR JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

GENTLEMEN.—Fibroids are so common in the uterus you may easily imagine that this organ enjoys a monopoly of this kind of tumour. Experience teaches that tumours agreeing in naked-eye and microscopic characters with uterine fibroids grow from the muscular coat of the gastro-intestinal tract. There are two clinical varieties, subserous and submucous, and each usually occurs as a surprise in the operating theatre.

The specimen that prompted me to select this subject for the lecture was obtained from a spinster, aged 49, under my care in the hospital, and from whom I removed an ovarian cyst tightly impacted in the pelvis. The uterus, flattened over the anterior wall of the cyst, was otherwise normal. In the course of the operation a tumour the size and shape of a bantam's egg was seen on the cæcum, near the base of the vermiform appendix. This tumour could be described as sessile and subserous; at its junction with the cæcum there was a plexus of arterioles and venules resembling a nævus. Its removal was a simple affair. When hardened and bisected, the cut surface displays the usual whorled appearance so

⁹ Since this address was written the valuable Report of the Consultative Council has been issued. I cannot well recast these paragraphs and must be content to welcome this Report and to express my agreement with it.

¹⁰ Such a laboratory was built before the war at Wolverhampton, and as I had urged the institution of such centres I was honoured by a request to open it. It was, of course, held up during the war, but I hear it is now fully at work again and much frequented by the practitioners of the district.

¹¹ See Sir Douglas Haig's Despatch of December, 1917: "The preventive medicine man has saved his tens of thousands."

common in slow-growing hard fibroids of the uterus. It is in structure a fibromyoma. Clinically it was harmless.

In comparison with this a specimen preserved in the Museum of the Royal College of Surgeons of England may be studied. A fibroid similar in shape, size, and microscopical structure grew from the ileum, led to torsion of the gut, and set up symptoms of acute intestinal obstruction. An operation was performed, the tumour and the implicated section of the ileum were resected, but this failed to save the patient, a man aged 48.

This specimen illustrates the danger of a small heavy tumour hanging like a bob on the end of a loop of ileum, an ideal arrangement facilitating torsion of the gut. How tightly the gut may be twisted is shown in Fig. 1, for all the coats of the intestine, save the serous,

FIG. 1.—Fibroid of the small intestine, in section, that led to volvulus. * At this point all the coats of the gut, except the serous, yielded under torsion. From a man aged 48. (Museum, Royal College of Surgeons.)

have yielded, and the serous layer at the line of torsion is diaphanous. Many similar records can be gathered from periodical surgical literature.

The Museum of the University of Leeds has a specimen in which a pedunculated fibroid of the small intestine caused a volvulus of the whole of the small intestine. Such a comprehensive volvulus can only occur in those rare instances in which the whole of the small intestine, from the middle of the duodenum to the end of the colon, is slung on a common mesentery, an arrangement found in the human embryo which occasionally persists in the adult and predisposes him to this serious form of volvulus. I reported such a case in *THE LANCET* (1908, i., 1837). Intestinal fibroids are sometimes so big that they are mistaken clinically, in women, for uterine fibroids. A woman, aged 40, had a large hard tumour in the pelvis; in the course of the operation a pedunculated spherical fibroid, as big as two fists, was found connected with the pelvic (sigmoid) colon by a pedicle. The uterus was normal and smooth. The structure of the tumour was that of a myoma which had undergone mucoid degeneration. (Dujarier and Khan.)

Migratory Uterine Fibroids.

Gynaecologists have occasionally reported the occurrence of a subserous uterine fibroid that has detached its pedicle, which may have connected it with the uterus, and formed a new attachment to intestine or omentum. Fibroids supposed to behave in this way have been called migratory uterine fibroids. Improved knowledge relating to intestinal fibroids may lead to a revision of opinion in regard to this curious question, especially as a fibroid of the intestine weighing 7 lb. has been removed from a man, aged 40, in whom it produced intestinal obstruction (University College Museum). These examples illustrate, what observation of tumours throughout the body teaches—the baneful effects of simple tumours depend entirely on their environment. The size of a tumour does not offer a measure

of its danger to life. A subserous fibroid occasionally grows from the stomach and reaches the size of a coconut; such a tumour merely produces uneasiness, but causes perplexity in diagnosis. A woman, aged 50, had signs indicating the presence of gall-stones, and a tumour the shape and size of a large pear; it could easily be moved about the abdomen in the neighbourhood of the gall-bladder. An operation revealed a large fibroid growing from the anterior wall of the stomach and an enlarged gall-bladder filled with stones. The tumour, which had been noticed many years, was coated with the white glistening cartilage-like tissue so common on chronic abdominal cysts and tumours long submitted to friction against the parietal wall. The gall-bladder and the tumour were removed. The latter proved to be a fibroid. Its removal involved resection of the wall of the stomach. This is almost invariably necessary with gastric fibroids. The patient was in good health six years after the operation.

Occasionally subserous fibroids of the stomach are large enough to reach as low as the hypogastrium; then the patient finds her way into the gynaecological department, where the tumour is almost invariably mistaken for an ovarian or a uterine fibroid, and serves to relieve the operative monotony engendered by specialism.

Uncomplicated fibroids of the stomach, like ovarian and uterine fibroids, are often passive tumours, but there are two stomachs in the Museum of Westminster Hospital which are exceptions to this rule. Each contains a pedunculated spherical tumour as big as a golf-ball growing within 5 cm. of the pyloric orifice. A brownish-black depression on the tumour marks its summit like an umbilicus. In structure this spherical solid tumour is a fibromyoma. One of the stomachs was obtained from a woman, aged 50, who was admitted severely collapsed in consequence of hæmatemesis and melæna. She died three days after admission. The second specimen was obtained from a man, aged 37, who also died in similar circumstances. The clinical histories of these cases were published by Gossage and Braxton Hicks. Paterson regards this kind of gastric tumour as clinically a sarcoma. Fibroids of the stomach are not common tumours. Outland and Clendinning, in 1913, collected records of 79 examples.

FIG. 2.—Portion of jejunum in section: a pedunculated fibroid led to intussusception. P, pedicle; A, abscess; F, fibroid. From a man aged 35. (Museum, Middlesex Hospital.)

SUBMUCOUS INTESTINAL FIBROIDS.

A submucous fibroid of the intestine is invariably solitary, and as it projects into the lumen of the gut the propulsive efforts of the muscular coat relentlessly endeavour to extrude it. Sometimes the pedicle is lengthened, and in extremely rare instances snaps. Commonly, the persistent muscular contraction of

the gut drives the tumour forward and leads to intussusception, with all its attendant evils—intestinal obstruction, which, unrelieved, usually ends in death (Fig. 2). There are cases on record in which a tumour of the small intestine has caused intussusception, and the intussuscepted portion of the gut has sloughed and been voided at the anus. It is curious that in many such cases the cause of such intussusception has been a secondary deposit of malignant disease. The chances of an intussusceptum sloughing are so few that it is the rule to interfere surgically, and with promptitude. In many cases the surgeon has no idea that a polypus is the cause of the trouble until he has completed the operation; unravelling the strangulated intestine he finds, perhaps, a fibroid no bigger than a ripe grape.

Some of the most serious complications occur when the tumour grows in the wall of the ileum, a common situation, and the polypus, propelled through the ileo-cæcal valve into the cæcum, drags a segment of the ileum with it.

Sir D'Arcy Power operated on a boy, aged 5, for a chronic ileo-cæcal intussusception. It was necessary to resect the ileo-cæcal segment, as it resisted reduction. Three weeks later a lump as big as a walnut was noticed on the boy's chest near the right nipple; this was a round-celled sarcoma. On re-examination of the intussuscepted gut a small mushroom-shaped tumour was found in the ileum an inch above the valve. This tumour was responsible for the intussusception and had the microscopic characters of a round-celled sarcoma. Many cases have been reported in which secondary deposits of malignant tumours in the small intestine have induced intussusception.

Sarcomatous Fibroids.

It is admitted by histologists that in minute structure some uterine fibroids closely resemble spindle-celled sarcomas, and it is impossible to decide whether such

tumours should be called sarcomas or fibromas. One way out of the difficulty is to call tumours of this kind sarcomatous fibroids. This is also true for intestinal fibroids. The piece of small intestine represented in Fig. 3 contains a tumour the size of a walnut. Shattock examined it critically and believes it to be a spindle-celled sarcoma with nuclei of striking size in many of the cells. It was successfully excised. In such cases the clinical course alone decides.

Intestinal fibroids, like uterine fibroids, often compromise the organ in which they arise:—

The subserous variety lead to volvulus (torsion) of the small intestine by their weight and movement, setting up acute and dangerous complications which often demand prompt and bold surgery.

Submucous fibroids of the intestine induce persistent propulsive movements in the muscular stratum of the gut, and these efforts almost invariably lead to intussusception, comparable to inversion of the uterus.

Intestinal fibroids are more dangerous than uterine fibroids, for they often cause obstruction, which is usually fatal unless relieved by surgical art.

Histologically they agree in the circumstance that the majority can be safely recognised as innocent tumours, but there are examples which cannot be distinguished from sarcomas.

FIG. 3.—Segment of small intestine in vertical section containing a fibroid. Excised from a woman aged 45. (Museum of St. Thomas's Hospital.)

INTESTINAL LIPOMAS.

Lipomas grow in the submucous tissue of the stomach and intestines—indeed, in any part of the alimentary canal from lips to anus—and are occasionally inimical to life. In the stomach small submucous lipomas the size of nuts have been described and are in the main pathological curiosities, but dangerous in the intestine. I found a submucous lipoma in the ascending colon, 5 cm. beyond the ileo-cæcal valve, in a man aged 44; he had had recurrent attacks of acute intestinal obstruction. The tumour, weighing 2 ounces, was successfully excised, and is preserved in the Museum of the Royal College of Surgeons of England. During the operation I noticed that the serous coat over the tumour showed a deep dimple, and the mucous membrane overlying the tumour was ulcerated. For a lipoma in a similar situation, in a woman, aged 31, Greenwood excised the cæcum and adjacent segment of the colon. The tumour is spherical, 4 cm. in diameter, and attached by a short pedicle to the wall of the colon. The mucous membrane covering the lipoma is ulcerated. The excised parts, with the tumour in situ, are preserved in the same Museum. Stabb operated on a man, aged 32, for intussusception of the ileum and found a submucous lipoma 75 cm. above the valve. He noticed a dimple in the serous coat overlying the tumour. The dimple suggests that the lipoma, though projecting into the gut, really arises in the subserous stratum of fat, and the dimpling of the serous coat is due to traction. This view is confirmed by a lipoma of the duodenum in the Birmingham Museum. It is a lobulated tumour depending from a pedicle 5 cm. long. Though the tumour lies within the bowel the serous coat is dragged in a little, and there is a small pit, or dimple, in the serous coat. The tumour clearly arose in the subserous tissue. The mucous membrane covering the tumour is ulcerated. The specimen was obtained from a dissecting-room subject.

The Museum of the Royal College of Surgeons contains a Meckel's diverticulum with a small lipoma apparently growing from the mucous membrane. The diverticulum had caused chronic obstruction; this led to an operation which ended fatally, but the lipoma was in no way responsible for the obstruction. The same collection contains a portion of the cæcum of a woman, aged 50, who suffered from constipation for many years. A lipoma grew within the folds of the ileo-cæcal valve, and the passage from ileum to cæcum is through a ring of fat covered with attenuated mucous membrane. It is a remarkable specimen. The cæcum was excised and the end of the ileum successfully anastomosed with the colon. (A. T. Compton, 1915.)

Lipomas, though simple and common, do occasionally destroy life; there is a submucous lipoma at the apex of an intussusception in the Leeds Museum.

DERMOIDS OF THE INTESTINE.

Dermoids are the rarest of all tumours that grow in the intestine. They have only been observed in the terminal segment of the large bowel. (Clutton, Danzel, and Port.) The Museum of the Middlesex Hospital contains an example growing from the posterior aspect of the rectum. It is as big as a walnut, and contains hair, grease, and a tooth, and was discovered post mortem. Several examples have been described growing from the mucous membrane of the rectum, and nearly all were found in women. The tumours are usually skin-clad and contain bone and teeth; in one of them, removed from a woman, aged 25, brain substance enclosed in a bony capsule was found. (Danzel.) The skin is usually pilose and the hair sometimes hangs in locks which extrude from the anus and cause annoyance. A pedunculated dermoid in the sigmoid flexure led to attack of intussusception in a girl aged 16. Clutton removed it and reported the clinical details in 1886.

Cystic dermoids occur in the rectum, and of this variety two examples are preserved in the Museum of St. Bartholomew's Hospital. One contains hair and a tooth; it was removed from beneath the rectal mucous membrane of a woman aged 39. The other, a multi-locular cyst as big as a fist, contains hair. This dermoid was detached and extruded during labour. A careful examination showed no communication with the pelvis

cavity. (Souttar.) Small ovarian dermoids obstructing delivery have been forced through the walls of the rectum and extruded at the anus. This explanation does not apply to Souttar's case.

POLYPI (PAPILLOMAS AND ADENOMAS).

The term polypus is commonly applied to any pedunculated tumour in the stomach or the intestines; the name is merely of clinical use, and has no significance for the pathologist. Pedunculated tumours of the gastro-intestinal mucous membrane may be fibromas, lipomas, dermoids, adenomas, or papillomas. This section will be concerned with adenomas and papillomas. A simple form, shown in Fig. 4, resembles in shape a large ripe blackberry, hanging from the wall of the pelvic colon by a broad triangular band

FIG. 4.—Solitary polypus of the pelvic (sigmoid) colon. The head of the polypus is crowded with intestinal glands. (Museum, Middlesex Hospital.)

of mucous membrane. The head of the polypus is crowded with intestinal glands. Polypi may be solitary or multiple and sometimes exist in vast numbers on the gastro-intestinal mucous membrane from the termination of the gullet to the anus. They present themselves in various forms, some as flattened processes of mucous membrane beset with glands; many of the tags are long and narrow, others have club-shaped ends. Many are true warts and villous in appearance; occasionally they form clumps resembling cauliflowers. Often polypi and warts are attached by broad bases and so clustered together as to recall a colony of anemones on a rock. Such clumps and clusters of polypi are sources of danger as they favour the occurrence of intussusception. This is proved by an extra-

ordinary set of specimens in the Museum of the Royal College of Surgeons, in which an abundant crop of glandular and papillomatous polypi grew from the mucous membrane of stomach, duodenum, jejunum, and ileum. The patient, a man aged 21, died after an operation for intussusception induced by a cluster of polypi in the jejunum. (W. Collier.) There are reasons for believing that intestinal warts sometimes behave like cutaneous warts and disappear spontaneously. The most serious features in their clinical history are these: They simulate colic cancer, but are more chronic and set up recurrent attacks of pain, diarrhoea, and bleeding from the bowel, anæmia, and loss of weight. Diagnosis is established by the sigmoidoscope. Multiple papillomas are sometimes associated with cancer, and may be the forerunners of cancer. In these grave matters they agree with warts on mucous and cutaneous surfaces generally. An example of cancer of the œsophageal region of the stomach in association with multiple polypoid adenomas has been reported by Stewart (1913). The common age for intestinal papillomas is from the fifteenth to the thirty-fifth year.

Common situations for multiple polypi are the rectum and colon, especially the pelvic colon, and in this situation they are discoverable by the

sigmoidoscope. In several instances long lengths of the colon have been successfully excised for this condition.

In the Middlesex Hospital (September, 1900) I excised from a German woman, aged 41, the whole of the pelvic colon (sigmoid flexure), which was crammed with luxuriant warts, set as closely as the bloom of a cauliflower. The lower end of the colon was closed with sutures and dropped into the pelvis, and the upper end implanted into the incision—permanent colostomy. She survived the operation eight years and died from intestinal obstruction caused by cancer.

In 1917 Ligat successfully excised the rectum and the colon as high as the splenic flexure from a man

FIG. 5.—Cylinder of colon inverted to show multiple polypi. The mouths of the intestinal glands are conspicuous. Ligat's case. (Museum, Middlesex Hospital.)

aged 36. It was beset with warts (Fig. 5). This man died two years later from acute pneumonia.

Lockhart-Mummery excised, in 1918, the cæcum and colon (29 inches in all) from a spinster, aged 24, for multiple polypi, and joined the cut end of the ileum to the stump of the pelvic colon, and subsequently cleared the rectum of polypi with the aid of a sigmoidoscope. This woman was in satisfactory health two years afterwards.

Polypi are uncommon in the stomach. Breschet (1817) described one that grew from the mucous membrane near the œsophageal orifice and had a pedicle $6\frac{1}{2}$ inches long; this allowed the head of the polypus to pass through the pylorus; it lay in the first part of the duodenum after death. The subject was a woman aged 69. Peter Thompson found a remarkable specimen in a woman, aged 75, a dissecting-room subject. A polypus that grew from the margin of the pylorus and adjacent part of the duodenum was involved in an intussusception which had dragged the pylorus and the first part of the duodenum into the second part of the duodenum. The mucous membrane covering the polypus contained gastric and duodenal glands.

Specimens of multiple polypi growing from the mucous membrane of the gastro-intestinal tract,

obtained in most instances from the post-mortem room, exist in all pathological museums. Surgeons are now supplying teaching collections with specimens obtained in the operating theatre. The value of such specimens is enhanced by complete clinical records and reports of microscopic examinations, without which many museum preparations are mere curiosities.

This lecture, in the main concerned with rarities, may be concluded with an example of a condition known as melanosis of the colon. Occasionally the mucous membrane of the large intestine from the ileo-cæcal valve to the anus is as black as ink. The specimen selected to illustrate this condition (Fig. 6) is an inverted

FIG. 6.—Cæcum and appendix turned inside out. The mucous membrane is charged with black pigment. From a woman aged 63. (Museum, Middlesex Hospital.)

cæcum with the vermiform appendix. The pigmentation begins sharply at the margin of the valve. In this instance the mucous membrane of the vermiform appendix is partially pigmented. Fortunately, the coloration is a curiosity and without sinister significance.

An instructive exhibition of fibroids, lipomas, and papillomas of the stomach and intestines was organised by Mr. Cyril Nitch and Mr. Herbert Paterson for the Surgical Section of the Royal Society of Medicine in May, 1920. The catalogue will be published in the Proceedings of the Society and should be useful to surgeons interested in the oncology of the gastrointestinal tract.

BONE-GRAFTING OF THE FRACTURED MANDIBLE.

WITH AN ACCOUNT OF SIXTY CASES.

BY GILBERT CHUBB, D.Sc., M.B., F.R.C.S.,

ASSISTANT SURGEON, THROAT HOSPITAL, GOLDEN-SQUARE; AND
 PLASTIC SURGEON, QUEEN'S HOSPITAL FOR FACIAL
 INJURIES, SIDCUP.

THE recent rapid progress in our knowledge of the bone-graft as a means of repair for the fractured mandible has been mainly due to the large number of such cases produced by the war. The transitory nature of this supply, and hence also of our opportunity for observing the results of surgical treatment, makes it desirable that accurate records and results obtained in all the cases with which I have so far dealt. I have, therefore, given as complete an account as space permits of the methods adopted and results obtained in the pre- and post-operative dental treatment of these cases I have had the active coöperation of Mr. B. Mendleson, and the results obtained owe much to his judgment and skill.

Analysis of Results.

The cases now described are 60 in number. All but three are gunshot fractures and all were operated upon at the Queen's Hospital for Facial Injuries, Sidcup. They are consecutive and unselected cases, and represent all the bone-grafts I had done up to the end of 1919. In two cases the graft was lost owing to sepsis. Erysipelas accounted for one of these and a discharging ear, not noticed prior to operation, apparently accounted for the other. In one case sinus formation resulted in non-union, and the eventual absorption of the graft. This case has since been regrafted. In another case the graft, which extended from molar to molar region, is healthy and the wound soundly healed, but union has not yet occurred at either end. In the remaining 56 cases, 93 per cent. of the series, firm bony union has been obtained. 51 of the cases had edentulous posterior fragments, and in 40 of these the loss of bone involved the region of the angle. In 16 of the latter the loss involved the ascending ramus also.

General Principles of Technique and Treatment.

The graft was obtained from the crest of the ilium in all but the first two cases. This source has several advantages. The size of the graft is practically unlimited. All sclerosed and doubtful bone can, therefore, be freely removed from the jaw fragments. The soft and vascular nature of the iliac crest greatly facilitates the manipulation of the graft and its subsequent union and consolidation. Furthermore, it is possible by varying the position on the crest to obtain a graft of a general curvature suitable to each particular case. There is a complete absence of post-operative disability, even when the anterior superior spine has been removed with the graft. The cases were, as a rule, up and about 14 days after the operation, and in no instance has there been any complaint of the hip.

The aim, in every case, has been to obtain a sound carpentering junction between the graft and the jaw fragments, the bones being so trimmed that they fit end to end with accurate apposition of the largest obtainable areas of exposed vascular bone tissue. In this position they are firmly wired together. This technique was originally adopted in order to control the edentulous fragment and to facilitate early union by accurate and continuous apposition of opposed bone tissue. The technique has the additional advantage that it allows of the early exposure of the graft to the stresses incidental to muscular movement without risk of disturbing the close contact of bone tissue obtained at the time of operation. That this early stress is a factor in determining rapid union was only gradually recognised as a result of the impracticability, in the great majority of the cases dealt with, of obtaining rigid post-operative immobilisation by means of splinting. Where no teeth are present on the posterior fragment the rigid splinting of the larger tooth-bearing fragment to the upper jaw does not relieve the grafted area from all

muscular stress. Yet it was found that in over 60 per cent. of the successful cases union was of ivory hardness at the end of three to four months. In several of the cases, in which no effective control existed for either fragment from the time of the operation onwards, rapid bony union nevertheless resulted. (Case 50, Fig. 12, Cases 51 and 52.) Union was already fairly firm at the sixth or eighth week.

Experience has, therefore, led me to regard the chief rôle of the dental splint as being the maintenance of correct occlusion during the operation. The tendency to lingual deviation of the large fragment can be subsequently prevented by the interlocking of the splint when in closed bite or by means of a flange. The preponderance of edentulous fragments, far from being a stumbling block, was a factor in the success obtained, in that they prevented me from obtaining the rigid immobilisation I had proposed adopting as a routine measure. In order, however, that this early exposure of the grafted mandible to stress may be a factor in determining rapid union, it is important that it shall not involve any disturbance of the apposed bone tissue—that is, the “carpentering” at the time of the operation must be sound. A poor mechanical junction which allows of the subsequent movement of the bones upon one another will result in non-, or long-delayed, union unless rigid immobilisation by splinting can be obtained.

Pre-operative Treatment.

The interval between the original injury and the bone plastic has averaged 15 months. In some cases the period was considerably longer, while in a few a successful bone-graft operation was performed as early as five months after the injury. Pre-operative treatment has consisted in the elimination of sepsis, the extraction of teeth involved in the fracture or tending to cause malposition, the correction of the latter, and, finally, the immobilisation of the jaw fragments. At least three months has been allowed to elapse between the last visible indication of sepsis and the operation, and the same rule has applied to the extraction of teeth involved in the fracture.

The main factors producing malposition are defective dental occlusion, unopposed muscular action, and scar contraction. When both fragments bear teeth the usual deformity is a combined lingual roll and deviation, the free ends of the bones being drawn together, partly by muscular action, partly by scar contraction; while faulty occlusion of molar teeth has caused the fragments to rotate till the lower teeth may come to lie horizontally in the oral cavity. In the case of the toothless fragment the presence of teeth in the upper jaw impinging upon the gum causes the fragment to shift outwards into the cheek, in which position unopposed muscular action elevates it to the outside of the maxilla. As far as the tooth-bearing fragments are concerned, early splinting in correct occlusion will prevent these deformities. In the case of the edentulous fragment, however, this prolonged splinting of the opposite side has the effect of causing a progressive contracture of the unopposed muscles. Deformity can be equally well prevented by making the necessary dental extractions and then providing the toothed fragment with a flange to prevent lingual deviation. In cases treated in this way the toothless fragment shows little or no deviation and elevation. If these deformities are present it is to a relatively slight extent and readily overcome. (Mendleson.)

The inward roll, if markedly developed, cannot be corrected. The teeth may be used for splinting, and are then removed to prevent further deformity. The mesial approximation in the slighter cases can be corrected by continuous elastic traction. In severer cases, however, division of the intervening fibrous tissue and forcible separation are needed, a procedure which has so far invariably resulted in the mouth cavity being opened submentally.

In a few cases an effort was made to depress the edentulous fragment by means of a saddle carried as a detachable extension of the splint. Pressure ulceration was avoided by affixing the saddle very shortly before the operation, and removing it soon afterwards. This is

liable to throw a heavy strain upon the graft. Moreover, the presence of a saddle at the time of operating prevents the complete exposure of the jaw stumps. (Fig. 13, Case 57.) The practice has been, therefore, to take the posterior fragment in its position of rest, however elevated, and to rely upon firm fixation to the graft for its post-operative control. One effective of this elevation, as Sir Frank Colyer has pointed out, is greatly to reduce the size of the gap to be filled by the bone-graft.

After previously acquired malposition has been, as far as possible, corrected, interlocking double “Gunning” splints are cemented on and bolted together in closed bite the day before the operation, and, in the majority of the cases, only removed from three to four months later.

Operative Technique.

The incision varies according to the position and extent of the fracture. For a loss of moderate extent in the region of the body of the mandible, it is placed well below the lower border of the jaw with a gentle convexity directed downwards. When the angle and ascending ramus are also involved, this incision is carried farther backwards below the ear, the convexity now being upwards. In this way an excellent approach is obtained to all parts of the ascending ramus, without risk of injury to the facial nerve. When the loss of bone extends farther forwards the incision is extended anteriorly with the same gentle sweep below the mandible and then, in the symphysis region, is carried sharply upwards, across the lower border of the jaw close to the middle line. In this way none of the depressor anguli oris branches of the facial nerve are caught, and a slight but nevertheless disfiguring palsy is thereby avoided. Fig. 1 shows this incision and its relation to the facial nerve and underlying mandible. In cases with a short symphysis loss, an adequate exposure is obtained by utilising the anterior portion of the above incision on either side; an inverted “Y” being produced, the stem of which lies in the middle line directly over the symphysis. For larger mesial losses a simple transverse incision is used, which passes horizontally across the neck, well below the lower border of the mandible on either side.

The jaw fragments are first exposed along their lower border and the soft parts separated from both surfaces with a raspatory, the length of bone exposed being determined by the extent of the obvious sclerosis. If teeth are present in the neighbourhood of the fracture, or if a saddle is in position on the posterior fragment, the exposure of the alveolar border is impossible, and extreme caution has then to be used in approaching this region. The oral cavity tends to pouch out between the fragments, often to a considerable extent, and as the tissue in this region is almost invariably scarred, it is wiser to leave a considerable mass projecting into the wound and shape the graft accordingly than to attempt too close an approach to the mouth cavity.

By means of gouge forceps¹ all sclerosed and doubtful bone is removed and the stumps suitably trimmed for fixation to the graft. They are then drilled as near as practicable to their upper border, care being taken to protect the deeper tissues lest the drill should enter the mouth, an accident which will render advisable the postponement of the operation. Pieces of tempered silver wire about 6 inches long are passed through each drill hole and their ends separately secured and held out of the way by forceps.

The fixation of the fragments in the case of the fractured mandible, due to the need for maintaining correct dental occlusion, accounts for much of the difficulty of bone-grafting in this region. Even in the case of the toothless posterior fragment the movement possible is a very limited one in an arc about the condyle. The graft has therefore to be cut accurately to fit the gap left between the jaw fragments on the completion of trimming. To facilitate this a piece of lead sheeting about 4 in. by 1 in., and stout enough to stand ordinary handling without distortion, is so cut and twisted that its ends lie evenly along the long diameter of the jaw “facets” and the sheet itself approaches these in a plane perpendicular to that of the facet. (Fig. 4.) This latter point is one of considerable importance, for it gives the plane of the short diameter of the facet, and thus enables the graft to be so cut that it is in accurate apposition throughout its thickness, and not merely along its outer edge, with the jaw fragments.

In the simpler type of case, when the jaw fragments lie more or less in the same plane, and their trimmed ends approximately face one another, the graft can be cut from the crest, shaped and drilled ready for wiring into the gap, with no other assistance than the lead template described above. When, however, the relation of the jaw fragments to one another is more complicated, it is impossible to cut the graft accurately by means of this template alone. In such cases a second or “check template” is used. (Fig. 5.) This is prepared from the first while the necessary transfer of the scene of operation to the hip is being arranged. In all essentials this second template constitutes a replica of the gap to be filled, the distance apart of the jaw fragments, the relative planes in which they lie, and the exact inclination of their trimmed ends to one another. The graft, cut with the aid of the first template, is placed against the check template. (Fig. 7.) If the fit is then found to be imperfect, the necessary alterations can be at once determined with an accuracy which would be wholly impossible were this test made in the wound itself.

In cutting the graft the template is so placed alongside the exposed crest that the future lower border of the graft corresponds to the free border of the crest, a portion of the latter being

¹ In the earlier cases I experimented with Albee's electrical saw, and with various types of hand saw, but none of these gave the precision of action, ease of manipulation, and freedom from injury to surrounding tissues which can be obtained by the use of gouge forceps. Chisels are contra-indicated on account of the risk of displacing the splints and of the strain they throw upon the teeth.

selected which possesses a curvature suitable to the particular case. A cut with the hand saw is then made across the crest, with an inclination in all directions corresponding to one end of the template. A steel strip is then slipped into the saw cut in order to facilitate holding the template, while a second cut is made in a position and at an angle corresponding to the other end of the template. (Fig. 6.) When, as is frequently the case, the two facets incline at an angle to one another, care has to be taken that the actual length of the graft is also correct. Fig. 6 shows the manner in which the template and steel strip are used in determining the plane for the second saw cut. The necessary measurement for the total length of the graft is indicated on both crest and template by a dotted line. The graft is now drilled at either end, the holes being placed close to the free border of the crest—that is to say, the future lower border of the graft. When it is not possible to use the whole thickness of the crest the latter is split with a chisel, the inner or outer portion alone being used. The graft is now removed with chisel and mallet. As this division determines the shape of its upper border regard must be paid to the amount of tissue to be accommodated between the jaw fragments. Throughout the cutting and drilling of the graft the latter remains attached to the ilium. Only when it is ready to be wired into position is it severed from the latter. The manipulation of the graft and the time occupied in the transfer to its final position are thus reduced to a minimum.

When the fracture involves the angle the posterior fragment, although thin, is often of considerable vertical extent, a narrow and elongated facet for apposition to the graft being the result. The latter is cut accurately to fit this elongated facet and the soft medullary tissue lightly gouged out so as to form a long and shallow groove (Fig. 8), into which the thin posterior fragment fits, embraced on either side by the slightly projecting compact bone of the graft. In this position the wiring holds the fragments beyond all possibility of subsequent displacement.

When the fracture involves the ascending ramus the atrophy seen in the region of the angle becomes more marked. The higher the loss extends, and the longer the period which has elapsed since the original injury, the thinner and more brittle the bone that is left. Fig. 9 (Case 30) shows an adaptation of the foregoing technique for dealing with such a condition.

When the loss extends anteriorly into or beyond the canine region it is impossible, owing to the curvature of the jaw, so to trim the fragment that the facet for apposition with the graft looks even

approximately towards the posterior fragment. The more anteriorly the loss extends, the more does the trimmed end of the jaw tend to face outwards. The sclerosis, which is always a marked feature of the anterior fragment, owing to the obliteration of its nutrient artery in the infra-dental canal, invariably extends further along the lower border of the bone than elsewhere. The effort to remove all trace of this condition usually results in the trimmed surface of the jaw stump facing obliquely downwards as well as outwards. (Fig. 10.) Fig. 2 shows the mode of cutting the graft in order to obtain a facet of sufficient breadth in this position. The anterior superior spine is exposed and an oblique saw cut through this, in a plane determined by the template, gives the facet for apposition with the anterior fragment.

In cases of extensive mesial loss involving not only the symphysis region but also part of each horizontal ramus, it is difficult to obtain a sufficient "bow" on the graft to accommodate the considerable mass of tissue intervening between the two jaw stumps, and to carry the chin and dentures out to anything like their normal position. A further difficulty is due to the inward rotation of the fragments. The first difficulty is surmounted by taking the whole of the anterior superior spine with the graft, the spine being retained or removed according to individual cosmetic requirements. (Fig. 3.) The second difficulty is got over by making the ends of the grafts correspond, the one with the thickening found at the junction of the middle and anterior thirds of the crest, and the other with the thickened bone lying directly above the anterior inferior spine. In this way broad areas are obtained at either end of the graft, and although the long axis of these facets cross those of the jaw facets often almost at a right angle, a very considerable area of vascular bone tissue remains in apposition.

The trimmed and drilled graft, on removal from the crest, is tested against the cheek template and at once transferred to the jaw wound. The wires, issuing from the deep aspects of the jaw fragments, are threaded through the corresponding holes in the graft and the latter slid down into position between the jaw fragments. If the technique has been successfully carried out the fit should be good, and no further alteration or adjustment needed. The graft is held firmly in position while the wires are given two or three turns upon one another and the ends cut short. No care has been taken to preserve the periosteum of the graft or of the jaw fragments, nor is any attempt now made to bring periosteum over the junction. Great care must, however, be taken that neither periosteum nor other soft tissue is allowed to intervene between

FIG. 15 (Case 24).

FIGS. 10, 11, 12, 13, 14, and 15 are semi-diagrammatic reconstructions of some of the grafted mandibles. They have been made for me by Mr. Hornswick from information supplied by radiograms, some of them stereoscopic, and by the lead templates. The size and position of the graft and jaw fragments are correct and follow as closely as possible the radiograms; the Mercator-like projection of the more outlying parts of the photograph has, however, been eliminated. The diagrams show the character of the "carpentering" employed, but do not show the nature of the union obtained.

FIG. 11A.

Microphotograph of the area X...X in Fig. 11 ($\times 15$). The section shows the line of junction between graft (left) and post fragment of jaw (right) six months after operation. A continuous layer of compact bone passes from the surface of the thinner jaw fragment to that of the thicker graft. There is a sudden transition from the compact structure of the jaw to the cancellous structure of the graft, no intermediate zone being present. There is no sign of absorption and redeposition in the graft. The arrow placed above the section marks the line of junction.

the apposed bone surfaces. In no case has it been possible to attribute sepsis to the presence of the wire, and successive radiographs entirely fail to suggest that the wire in any way inhibits bone formation.

The wound is closed, when practicable, in two layers, deeper tissues, muscle, fascia, or maxillary gland being all drawn together over the graft with deep catgut sutures, not merely to serve as an additional covering between this and the skin flap, but also, and mainly indeed, in order to obliterate all spaces round the graft. The closed incision is finally painted over with tinct. benzoin. No dressing or drainage-tube is used. A careful watch is, however, kept for the first few days, and any serum or blood collecting is drawn off through a small opening by means of a Bier's suction glass; this process being repeated, if necessary, on successive days.

Permanence and Functional Value of the Grafted Mandible.

The permanent character of the repair effected by the bone-graft can only be determined by the lapse of time. In some of the cases in the present series more than a year has elapsed since the operation, and the only change shown in successive radiographs is one of progressive consolidation. In Case 44 a fibrous union had resulted owing to failure to remove all the sclerosed tissue from the anterior fragment. At the operation for resecting and regrafting this non-union, six months after the original operation, the posterior union, which had been firm clinically since the splints were removed, was represented by a faint rounded ridge where the thicker graft passed into the thinner posterior fragment. Both the graft and the ridge marking the line of union showed a hard smooth surface exactly resembling that of the adjacent jaw fragment. A small piece, indicated by dotted lines in Fig. 11, was resected for examination. During its removal the vascularity of the graft was found to be in every way as good as that of the adjacent jaw fragment. A microphotograph of a section of this fragment in the direction of the line X.....X is seen in Fig. 11 A. This section is in complete agreement with the X ray appearance presented by the union in other cases. It is often possible to recognise the uninterrupted passage of the bone architecture of the graft into that of the mandible. This is particularly striking when viewed stereoscopically and stands in sharp contrast to the fibrous union, however firm this may be clinically. In Case 26 this contrast is seen side by side on the same horizontal ramus. The radiograph shows the spontaneous union as a white line of fibrous tissue which has undergone no change in appearance. The graft, on the other hand, has merged so completely with the mandible that it is difficult to see exactly where the original junction was situated.

In determining the subsequent functional value of the grafted mandible there are several factors to be taken into account, besides the permanent character of the graft and its bony union. The prolonged disuse results in a weakness of the muscles of mastication and the same cause greatly increases the normal periodontal sensitiveness. That these, however, are not permanent conditions is shown by the nature of the diet of some of the patients within a few months of the operation. By the method adopted for obtaining the graft, the upper or alveolar border is constituted by open cancellous tissue. Successive radiographs show that under the influence of the stress and strain to which the graft is subjected in the normal use of the jaw the architectural structure becomes modified in accordance with Wolff's law, and a compact layer of bone is formed completely encircling the central tissues of the graft. In several cases I have found the graft able to bear directly the pressure of a denture within a few months of the operation.

The Fate of the Free Graft.

General opinion is, on the whole, tending towards the view that the free graft remains alive and takes an active osteo-genetic share in the union. The graft, with its thin tables of compact bone, is relatively more transparent in the earlier post-operative radiographs than is the far denser mandible. There is, however, no constant post-operative increase in this relative transparency. On the contrary, successive radiographs show a uniform increase in the opacity of the graft. The small area of vascular tissue exposed in the case of many of the posterior fragments, and the dense and relatively avascular nature of the anterior fragment,

taken in conjunction with the large size of many of the grafts, make it very difficult to imagine that the latter owes its rapid consolidation, wholly, or even mainly, to invasion and replacement by osteogenetic tissue from the mandible. The behaviour of the graft in the presence of sepsis is even more suggestive. In Case 16, in which the graft was of considerable size, there was extensive suppuration after the operation. A month later a large sequestrum came away. Union nevertheless occurred at both ends, and a subsequent radiograph shows the upper or alveolar border of the graft, together with the whole of its anterior portion, still in position and firmly united at either end. All sepsis has since disappeared, and the final result is excellent. That we are not dealing with an involucrum is, I think, shown by the appearance of the anterior end of the graft, with its close fit to the jaw fragment and the wiring still in position. The view that the sequestrum was thrown off by the living graft is supported by three other cases in which small sinuses over the graft closed after the separation of one or more small sequestra from the latter, without leading to its infection, or in any way interfering with the progress of union. In one case sepsis has resulted in the infection of the graft. The appearance of this case, with the entire absence of any attempt at union and the irregular rarefaction of the graft, stands in striking contrast to that of the other cases.

I have only seen one case in which dead bone, a boiled autogenous graft, was used. The graft remained sterile and the wound healed by first intention. Months afterwards, however, there was still no trace of union, or of any invasion of the graft by bone tissue from the jaw fragments, and successive radiographs unmistakably show the graft undergoing progressive absorption.

Summary.

The series consists of 60 consecutive cases of bone-grafted mandibles. Of these all but two were free autogenous grafts from the ilium. 51 possessed edentulous posterior fragments and in 40 of these the loss involved the region of the angle. In 16 of the latter the loss involved the ascending ramus also. Firm bony union was obtained in 56 of the cases, 93 per cent. of the series.

The graft and jaw fragments were so trimmed as to fit accurately end to end, with the largest obtainable areas of exposed vascular bone tissue held in close contact by firm wiring. The close apposition results in early bony union, while the firm fixation allows of the bones being subjected at once to some degree of muscular strain without fear of displacement, thus leading to the early consolidation of the primary union. In over 60 per cent. of the successful cases the union was of ivory hardness on the final removal of the splints, three to four months after operation.

Note.—The favourable influence of early exposure to stress is strikingly shown by seven cases grafted while the above paper was in the press. The splints in each case were removed in the second or third week, and in one case within three days of the operation, a flange being fitted to prevent lateral strain upon the graft. Four of these cases were firmly united within the month, and the remaining three were firm before the end of the third month. In two cases in which union was secured within the first month a previous bone graft (not by the author) had been attempted and failed. In one of these the loss involved the greater part of the ascending ramus. In only one case did the posterior fragment bear teeth, one molar tooth being present on each fragment. The splints in this case were, however, loose from the time of the operation onwards. In one case no teeth were present on either fragment, and there were only two teeth in the upper jaw.

PORTSMOUTH AND SOUTHERN COUNTIES EYE AND EAR HOSPITAL.—At the annual meeting of this hospital held in the Town Hall, Portsmouth, on June 24th, it was reported that the new wing erected in 1914 had been paid for. The general financial position was one for anxiety. There was a decrease in the current revenue, a deficit on the year's work of £398, and a bank overdraft of £751.

THE PARATYPHOID "C" BACILLUS AS A CAUSE OF PARATYPHOID FEVER.

BY LEONARD S. DUDGEON, C.M.G., C.B.E.,
F.R.C.P. LOND.,PROFESSOR OF PATHOLOGY, UNIVERSITY OF LONDON;
ANDA. L. URQUHART, O.B.E., M.B. EDIN., D.P.H. LOND.,
SENIOR ASSISTANT BACTERIOLOGIST, ST. THOMAS'S HOSPITAL.

(From the Pathological Department of St. Thomas's Hospital and the British Laboratories attached to the Balkan Forces.)

(Bacteriological Investigations in Macedonia, 1916-17-18.)

IN 1916 Professor Ludwig Hirschfeld, bacteriologist-in-chief to the Royal Serbian Army, isolated by blood culture a bacillus which, for reasons about to be defined, he labelled "Paratyphoid C." The patients from whom the organism was cultivated were suffering from "enterica," but no known bacillus of the enterica group was isolated and no serological confirmation was obtained. Professor Hirschfeld considered that the organism was distinct from the known paratyphoid bacilli isolated from the Serbian soldiers suffering from enterica, and he decided to add this bacillus to his preventive vaccine. In December, 1916, a vaccine was prepared in his laboratory at Sedes which contained *B. typhosus* and paratyphoid bacilli A, B, and C, and *V. cholerae*. This vaccine was employed in the Serbian army for preventive inoculation in 1916, 1917, and 1918. In December, 1916, a bacillus was obtained by blood culture from a Serbian soldier at an Anglo-Serbian hospital suffering from enterica, and as it was found to be atypical it was sent to one of us (L. S. D.) for further investigation. This organism proved to be a strain of the para. C bacillus. An antiserum which was prepared with this strain of para. C corresponded to the para. C antiserum supplied to us by Professor Hirschfeld, and the organisms were in all respects similar.

It was decided to prepare a para. C antigen for the laboratories in Macedonia similar to those employed for the typhoid and paratyphoid A and B reactions at the Central Laboratory, and also a supply of para. C antiserum. At subsequent periods this organism was isolated by blood culture from Serbian soldiers (6) in Anglo-Serbian hospitals, and further strains were obtained from the faeces of Serbs and others (10) who were suffering from severe diarrhoea or enterica. The organism was not isolated by us or our co-workers from the urinary tract. It is now known that, in addition to typical enterica, the *B. paratyphosus* C may give rise to infective conditions, such as severe diarrhoea, broncho-pneumonia, and general sepsis.

Castellani,¹ in an article on typhoid infections in the "Adriatic-Balkan Area," refers to a number of "atypical or mixed enterica infections." He states that six strains were isolated with the cultural characteristics of the *B. paratyphosus* B, but serologically distinct, and three strains culturally similar to the paratyphosus A, although distinct serologically.

Archibald, Hadfield, Logan, and Campbell,² in their report on the diseases affecting the troops in the Dardanelles, state that out of 147 cases of enterica, 21 were due to *B. typhosus*, 41 to *B. paratyphosus* B, and 70 to *B. paratyphosus* A, while 15 inagglutinable para. A strains and 14 para. B were also obtained.

Kennedy,³ in an article in the *Journal of the R.A.M.C.*, reports that in 1914 at the Enteric Convalescent Depot at Naini Tal he found five inagglutinable strains by blood culture, resembling *B. paratyphosus* A or B.

Macadam,⁵ Mackie and Bowen⁴ isolated a bacillus in

Mesopotamia which appears to be identical with the *B. paratyphosus* C of Hirschfeld. Macadam⁵ isolated this bacillus from 7 cases by blood culture, and on 2 occasions post mortem (1 from lung and 1 from bile).

Mackie and Bowen⁴ isolated the para. C bacillus from 12 cases, 10 from the blood stream, 1 from the urine, and 1 from the liver. The authors state that the paratyphoid C bacillus does agglutinate with some samples of antiparatyphoid B serum to low titre, and also that the para. B co-agglutinins are removed from the para. C antiserum by the para. C bacillus. Macadam noted on several occasions zones of inhibition of agglutination with the para. C reaction. Neukirch⁶ while working with the German Army refers to his findings in Turkey. He cultivated from the blood, urine, and faeces, bacilli allied to the paratyphoid B. bacillus, but serologically distinct. Although he does not give the name para. C to these organisms, it is probable from his results that some of his strains were identical with the bacillus of Hirschfeld. On clinical evidence some of the cases were typical enterica, others were dysenteric in character. Dienes and Wagner⁷ also obtained similar findings to those recorded by Neukirch.

Garrow⁸ has published a case recently of a paratyphoid C infection which occurred in East Africa. The patient presented the clinical features of a typical enterica infection. The paratyphoid C bacillus was recovered from the blood stream and the patient's serum contained specific agglutinins for this organism. No paratyphoid B agglutinins were present.

Fatal Cases.

We were able to obtain details of two cases of fatal para. C infection in the Balkans, although other cases no doubt occurred.

CASE 1.—Macedonian labourer. Investigated by Captain J. Anderson, R.A.M.C. *B. paratyphosus* C was isolated by blood culture from this patient who was profoundly ill with "enterica," and subsequently died. At the autopsy the spleen was found to be much enlarged, very soft, and congested. There was no intestinal ulceration, but marked patchy congestion of the intestinal wall.

CASE 2.—A Macedonian woman was admitted to hospital at Voden, and died on the eighteenth day after a severe illness. This patient was diagnosed clinically as enterica. No malarial parasites were found in the blood film, and the cerebro-spinal fluid was normal in all respects. An agglutination reaction on the thirteenth day of the disease gave a $\frac{500}{5000}$ reaction to para. C, while two days later it reached $\frac{1000}{5000}$, but no reaction occurred with the typhoid, para. A, or para. B antigens. No further observations were possible, as the patient was many miles away from a British unit.

Agglutination Reactions Obtained in Macedonia.

Captain Anderson, bacteriologist to an Anglo-Serbian Hospital, made the following observations:—

He examined the blood of 104 patients for evidence of typhoid and paratyphoid A, B, and C agglutinins with the antigens supplied by us. Of these patients, 11 were British, 9 French, 58 Serbians, and the remainder included the "mixed bag" of people met with in the Balkans.

Only 2 out of a total of 58 Serbians gave a reaction to the para. C antigen. In the first case the Serb had been inoculated against the enterica group one month previously with Hirschfeld's mixed vaccine and gave a reaction of $\frac{500}{5000}$ for para. C, $\frac{1000}{15000}$ for typhoid, and $\frac{50}{10000}$ for para. A, but no para. B reaction. In the second case the Serbian soldier had been inoculated against the enterica group one year previously, and showed a $\frac{20}{5000}$ reaction to para. C, a slightly greater typhoid and paratyphoid B reaction, but none to para. A. Further, although 4 cases gave a reaction of 1 in 100 or over with our typhoid antigen, and one case to $\frac{1500}{8000}$ with the para. B, there was no reaction at the lowest limit with the para. C antigen.⁹

To elucidate further the question of degree of response to the para. C portion of the quadruple vaccine this organism was embodied in the vaccine to be employed for the inoculation of 20 volunteers amongst the Bulgar prisoners, while the remainder received the triple vaccine. The blood of each man was tested for his agglutination response to typhoid, and para. A, B, and C before inoculation, and again ten days later. The local and general effects of the quadruple vaccine were considerable in many cases, while in all a definite local reaction occurred. In five cases pyrexia exceeded 100° F. on the second day after the inoculation, but in two of these men it was probably malarial in origin.

⁹ It is a matter of considerable difficulty to obtain reliable information concerning preventive inoculation among the Serbian soldiers.

In every instance enlargement and tenderness of the axillary glands occurred.

Agglutination Response.

It will be seen from Table I. that of the 20 Bulgars whose blood was tested before inoculation 10 gave a $\frac{50}{15000}$ reaction to the typhoid antigen, and 1 a $\frac{100}{15000}$, while only 3 reacted to the para. A antigen, one of them to the extent of $\frac{200}{10000}$. No reaction occurred with the para. B antigen, and in only one instance with the paratyphoid C. The agglutination response, therefore, to the paratyphoid antigens was feeble or entirely absent. No evidence was obtainable as to whether these men had been inoculated previously with a triple vaccine, although they had received a typhoid vaccine some months previously.

The inoculation of our quadruple vaccine excited an active response to the T. A and B antigens, but a C reaction occurred in only one instance (Case 2); here a reaction of $\frac{500}{5000}$ was obtained before inoculation, which rose to $\frac{100}{5000}$ ten days after the injection of the vaccine. In two instances a B reaction of $\frac{1000}{5000}$ was produced, but no C reaction was obtained.

The same strain of para. C bacillus was employed for the preparation of the vaccine and antigen.

TABLE I.—Agglutination Response to One Dose of Quadruple Vaccine in Bulgarian Soldiers.

Case.	Agglutinin response before inoculation.				Agglutinin response 10 days after inoculation.

20	50	50	0	0	200	200	1000	0

End-point of antigens, typhoid, 15,000; A, 10,000; B, 8000; C, 5000.
Note: 0 = 1/25, no reaction.

These agglutination reactions with the Bulgar prisoners agreed with our findings obtained with the Serbian soldiers, and may serve as an explanation for the absence of a reaction in the latter, although we had believed them to be inoculated with Hirschfeld's mixed vaccine. It must be remembered, however, that it was possible to test the agglutination reactions among the Bulgars on one occasion only after the injection of the vaccine, as they were required for military purposes. Further, the highest agglutination reaction observed among the cases of para. C infection by us was $\frac{500}{5000}$.

Animal Inoculations.

A rabbit was inoculated subcutaneously with 50 million of each organism in a quadruple vaccine, nine days later with 100 million, and again eight days later the dose was repeated. The agglutinin response is tabulated in Table II.

TABLE II.—Rabbit Inoculated Subcutaneously with T. A B C Vaccine.

T.	A.	B.	C.	
0	0	0	0	Before inoculation.
50 Million T. A B C Subcutaneously.				
$\frac{100}{15000}$	$\frac{100}{15000}$	$\frac{50}{8000}$	$\frac{200}{10000}$	9 days after first inoculation.
100 Million T. A B C Subcutaneously.				
$\frac{1000}{15000}$	$\frac{1000}{15000}$	$\frac{50}{8000}$	$\frac{1000}{15000}$	8 days after second inoculation.
$\frac{1000}{15000}$	$\frac{1000}{15000}$	$\frac{50}{8000}$	$\frac{1000}{15000}$	9 days after third inoculation.

A second rabbit was inoculated subcutaneously with 10 million of each organism employed in the quadruple vaccine, and seven days later with 20 million, but a similar agglutination response was obtained as shown in Table II.

The two rabbit experiments just referred to show that these animals give a response to each member of the quadruple vaccine when the immunisation has been obtained with large or average doses.

TABLE III.—To Show the Agglutinin Content of Immune Rabbit Sera Titrated with our Standard Antigens as Used in the Above Experiments.

Serum.	Antigen.	Agglutination end-point.	Serum.	Antigen.	Agglutination end-point.

Para. A	Para. A	$\frac{10000}{15000}$	Typhoid	Para. B	$\frac{1000}{15000}$

Cultural Tests.

Every strain of para. C tested by us has shown the same cultural reactions, and, further, these reactions have remained constant in stored laboratory cultures.

The organism is a motile Gram-negative bacillus. It ferments glucose, mannite, maltose, dulcitol, and sorbite with gas production, while cane sugar and lactose remain unchanged. Litmus milk is first acidified, the medium gradually returns to neutral point, and finally is rendered alkaline in three to four days. No strain which we have investigated has produced indol.

Since the above observations were made in Macedonia we have further investigated the serological reactions of the para. C bacillus and compared its antigenic properties with the other members of the enterica group of organisms. Rabbit antisera have been prepared and the reactions to the enterica group, including the para. C bacillus, have been studied. Three types of vaccines were employed: (1) heat-killed, (2) formalin-killed, and (3) vaccines grown in 1 per cent. dextrose¹⁰ and killed with formalin. Para. C vaccines have also been employed for the inoculation of men who offered their services, and the antigenic properties were observed in these healthy individuals, many of whom were ex-soldiers and whose sera contained typhoid and paratyphoid (A and B) agglutinins.

Methods of Preparation of Vaccines.

The vaccines employed by us in these investigations were made as follows:—

1. *Heat-killed vaccines.*—A 24-hour agar culture of this organism was emulsified in normal saline, filtered through fine linen, and heated to 56° C. for one hour. The vaccine was then placed in the ice chest, and later tested for sterility. Suitable dilutions of the emulsion were made with saline containing 0.25 per cent. carbolic acid.

2. *Formalin-killed vaccines.*—A 24-hour agar culture was emulsified in normal saline and filtered as above. To the emulsion 0.1 to 0.14 per cent. of formalin was added and the emulsion placed in the ice safe till sterile. Suitable dilutions were made as above.

3. *Acid dextrose vaccines.*—Organisms were grown in 1 per cent. dextrose in peptone water and the tubes were incubated for 24 hours. The acidified medium was centrifugalised and the supernatant fluid discarded. The deposit of organisms was diluted with saline containing 0.1 to 0.14 per cent. of formalin and treated subsequently as in method 1.

Some of the volunteers received one type of vaccine only, and others one type followed by another. Rabbits were also inoculated with the vaccines and the agglutinin response tested.

The antigens used were made as follows:—

The organism was subcultured daily for 10 days to obtain an active growth. Agar flasks were inoculated with the tenth subculture, and the flasks were incubated for 24 hours. The growth was washed off with 0.1 to 0.14 per cent. formal saline. The emulsion was filtered and placed in the ice chest till sterile. The antigen was diluted to standard, i.e., 1000 million bacilli per c.cm., and 0.25 per cent. carbolic acid added. The end-point of agglutination is expressed as a fraction, the numerator denoting the highest dilution in which agglutination occurred, the denominator being the end-point of the antigen on its homologous antiserum. Our methods for the agglutination reactions were constant, and we followed in certain details the technique recommended by Dreyer. The tubes were incubated at 55° C. for two hours, and the readings taken after half an hour at room temperature.

The absorption tests were carried out as follows:—

To one volume of the serum diluted to 1 in 10 with normal saline a creamy, thick emulsion of the absorbing bacillus¹¹ was added in three doses, i.e., one half and two quarter

¹⁰ This vaccine will be called subsequently in this paper the "acid dextrose vaccine."

¹¹ These emulsions were approximately of the same strength.

volumes, at intervals of three hours, and incubated at 55°C., unless otherwise stated. After nine hours the tubes were placed on the ice overnight. The treated emulsions were centrifuged and the test performed on the supernatant clear fluid. A control saline and serum tube was heated together with the emulsions.

Agglutinin Response of Rabbits to Injections of the Para. C Bacillus.

A rabbit was inoculated intravenously with a formol agar vaccine of the para. C bacillus, and the response is recorded with the dosage in Table IV.

TABLE IV.—*Intravenous Inoculation of a Rabbit with Formol Agar Vaccine of the Para. C Bacillus.*

Date of inoculation.	Dose.	Date of testing serum.	End-point of agglutination.
20/10/19	100 million	24/10/19	$\frac{500}{20000}$
24/10/19	250 "	26/10/19	$\frac{10000}{20000}$
30/10/19	500 "	31/11/19	$\frac{20000}{20000}$

This rabbit gave a rapid serum response $\frac{200000}{200000}$, that is, to the end-point of the antigen.

This para. C antiserum was tested against the stock laboratory antigens, *B. typhosus* and *B. paratyphosus* A, B, and C, with the following results: A control tube containing normal human serum and the para. C antigen was also observed.

Typhoid antigen and para. C antiserum					...	0
						20000
Para. A	1:1	1:2	1:3	1:4	1:5	0
						20000
Para. B	1:1	1:2	1:3	1:4	1:5	0
						20000
Para. C	1:1	1:2	1:3	1:4	1:5	0
						20000
Para. C	1:1	1:2	1:3	1:4	1:5	0
					normal serum	20000

From these results it will be seen that the para. C agglutinin is specific, as no reaction occurred with the typhoid or paratyphoid (A or B) antigens.

TABLE V.—*Absorption Test. Para. C Antiserum $\frac{200000}{200000}$, Saturated with B. typhosus and Paratyphoid Bacilli A, B, and C.*

Antiserum.	Absorbing bacillus.	Titre after absorption.	Control saline serum.
Para. C.	<i>B. typhosus</i> .	10000*	20000
"	<i>B. para. A.</i>	150000	50000
"	<i>B. para. B.</i>	15000*	20000
"	<i>B. para. C.</i>	10000	20000

* In all cases 1 in 15,000 dilution gave complete agglutination; the end-point was not obtained.

It will be seen from Table V. that no absorption of the "C" agglutinins followed the addition of the typhoid and the A and B bacillary emulsions. The effect of absorbing the stock para. B antiserum with emulsions of para. B and C showed that a B antiserum of 3333 titre was completely desaturated by a para. B bacillus, while the para. C emulsion removed none of the para. B agglutinins.

It will be seen from the above-mentioned experiments that the other members of the enterica group absorbed none of the agglutinins from a para. C antiserum of high titre, and that the para. C bacillus absorbed none of the agglutinins from this sample of para. B antiserum. It is necessary, however, to realise that some para. C antigens have a definite B fraction, while apparently a B fraction may develop in a C antigen which was pure when the organism was first isolated.

We conclude that the para. B and para. C bacilli, although identical in fermentation reactions, are distinct bacteria as judged by serological reactions, as Professor Hirschfeld originally stated.

The agglutinin reactions and absorption tests with a para. C antiserum were tested against two strains of Gaertner bacilli and Aerttrycke bacilli kindly supplied to us by Colonel S. L. Cummins, A.M.S., with the results shown in Table VI. It will be seen from this table that the paratyphoid C strain has apparently no relationship with the Gaertner or Aerttrycke group of bacteria, as in no case was any agglutination or absorption phenomenon observed.

Sir Frederick Andrewes, to whom we are greatly indebted for showing us the results of all his investigations, has found that typical strains of suipestifer and para. C are identical serologically. We have tested the *original strain* of para. C isolated by Hirschfeld in 1916 with a standard strain of suipestifer furnished by Andrewes. On serological evidence the two strains are identical. Cultural differences with xylose, arabinose, and dulcitol may occur with some strains

of suipestifer and para. C. The results obtained by him would appear to us to be of the utmost importance epidemiologically.

TABLE VI.—*Agglutinin and Absorption Reaction of Five Bacteria on Para. C Antiserum.*

	Agglutinin reaction.	Absorption reaction.
Para. C antiserum on—		
Para. C bacillus	$\frac{0}{20000}$	$\frac{250}{20000}$
Gaertner, Bainbridge	$\frac{0}{20000}$	$\frac{15000*}{20000}$
Gaertner	$\frac{0}{20000}$	$\frac{15000*}{20000}$
Aertrycke, Newport	$\frac{0}{20000}$	$\frac{15000*}{20000}$
Aertrycke, Mutton	$\frac{0}{20000}$	$\frac{15000*}{20000}$

* The end-point of the reaction was not determined.

The Effects of the Injection of Multiple Vaccines Containing B. typhosus and B. paratyphosus A, B, and C into Rabbits.

Rabbits were injected with the quadruple vaccine subcutaneously and intravenously, as noted below. Three types of vaccines were employed: (1) heat-killed, (2) formol-killed, and (3) acid dextrose.

TABLE VII.—To Show Results of Injecting Subcutaneously
equally graduated Doses of Heat-killed Vaccines of
B. typhosus and B. paratyphosus A, B, and C.

Date of immunisation.	Dose.	Date of testing serum.	End-point of agglutination to—			
			T.	A.	B.	C.
5/1/20	100 million	5/1/20	0 8000	0 6000	0 5000	0 2000
		8/1/20	0 8000	0 6000	0 5000	0 2000
12/1/20	200 "	12/1/20	50 5000	50 5000	50 5000	0 2000
		19/1/20	200 8000	250 6000	400 6000	100 2000
	500 "	26/1/20	1000 8000	1000 6000	1500 8000	2000 2000

From Table VII, it will be seen that the agglutinin response was present to each component of the quadruple vaccine when the heat-killed vaccine was employed.

A similar experiment was carried out with the formalin-killed vaccine, and in this instance, as in the case with the heat-killed vaccine noted above, a similar rise of agglutinins was noted. The quadruple vaccine was given in doses of 100, 200, 400, and 500 million at six-day intervals, and the agglutinin titre of the serum rose from zero to 1000 with *B. typhosus*, 500 with para. A, 500 with para. B, and 2500 with para. C antigens.

TABLE VIII.—To Show the Results of the Subcutaneous Inoculation of Rabbits with the Quadruple Acid Dextrose Vaccine.

Date of inoculation.	Dosage.	Date of testing serum.	End-point of agglutination to—			
			T.	A	B	C
19/1/20	100 million	19/1/20	$\frac{0}{8000}$	$\frac{0}{6000}$	$\frac{0}{5000}$	$\frac{0}{20000}$
		26/1/20	$\frac{0}{8000}$	$\frac{25}{6000}$	$\frac{0}{5000}$	$\frac{25}{20000}$
30/1/20	200 "	30/1/20	$\frac{25}{8000}$	$\frac{100}{5000}$	$\frac{25}{6000}$	$\frac{100}{20000}$
7/2/20	400 "	12/2/20	$\frac{100}{8000}$	$\frac{100}{6000}$	$\frac{100}{5000}$	$\frac{200}{20000}$

A second rabbit was inoculated in this case intravenously with the quadruple acid dextrose vaccine, and the agglutinin response is recorded in Table IX.

TABLE IX.—To Show the Immediate and Active Response
Obtained with Quadruple Acid Dextrose Vaccine when
Injected Intravenously.

Date of inoculation.	Dosage.	Date of testing serum.	End-point of agglutination to—			
			T.	A	B	C
30/1/20	100 million	30/1/20	$\frac{0}{5000}$	$\frac{0}{5000}$	$\frac{0}{5000}$	$\frac{0}{10000}$
7/2/20	200 "	4/2/20	$\frac{0}{5000}$	$\frac{100}{2000}$	$\frac{500}{5000}$	$\frac{200}{1000}$
		11/2/20	$\frac{100}{5000}$	$\frac{500}{5000}$	$\frac{1500}{5000}$	$\frac{1000}{10000}$

The difference in response is very marked, as shown in these two tables. In 19 days the acid dextrose vaccine given subcutaneously excited but a feeble response to all four

antigens, whereas the same vaccine given intravenously excited in 11 days a marked reaction with the paratyphoid strains, but not with the typhoid.

It was thought that this feeble response to the acid dextrose vaccine employed subcutaneously might be due to the absence of reaction in the tissues at the site of inoculation. Two further rabbits were inoculated subcutaneously—(a) with acid dextrose vaccine only, while (b) received 0.5 c.cm. of ether at the site of inoculation to ensure a tissue response. In Rabbit (a) the agglutinin reactions were again feeble, similar to the previous experiment referred to in Table VIII., while in the case of Rabbit (b) no advantage was obtained by exciting a marked local reaction by means of ether. Rabbit (a) subsequently received two injections of the quadruple formol-killed vaccine subcutaneously and Rabbit (b) one injection of acid dextrose vaccine intravenously, and in both cases a marked reaction to all four antigens occurred.

From these experiments it may be concluded that as an antigen for the preparation of typhoid and paratyphoid (A, B, and C) agglutinating antisera the heat-killed and formol-killed vaccines are of greater utility than the acid dextrose if the subcutaneous method of inoculation is employed, but the acid dextrose vaccine gives an equally good result if paratyphoid vaccines are injected intravenously.¹²

The Result of the Subcutaneous Inoculation of Man with Paratyphoid C Vaccines.

Over 30 volunteers have been inoculated subcutaneously with paratyphoid C vaccines. The highest agglutinin responses were obtained with the formol-killed vaccines. The inoculation dosage varied in amount, and the resulting serum reactions appeared to have no relationship with the number of bacilli injected. Thus, after a single dose of 250 million of the formol-killed vaccine, a titre of $\frac{1500}{20000}$ was obtained; in another instance, although 11 inoculations were given over a period of four months, seven of which contained 1000 million bacilli, the para. C agglutinins never rose above $\frac{4000}{20000}$, while in other cases no reaction occurred. Two healthy men received two injections each of 250 and 500 million of a para. C vaccine at an interval of eight days. In one instance the titre of the serum to para. C rose from 0 to 1500 in four weeks, while in the other instance no response was effected in the same period. It would appear, therefore, that the agglutinin response to paratyphoid C in any particular individual is uncertain and may be altogether absent. These findings agree with our observations made on the Serbian soldiers, and on the Bulgarian prisoners in Macedonia.

Agglutination Response to the Inoculation of Formol-killed Paratyphoid C Vaccines.

Twelve men were inoculated with the formol-killed vaccine, and in all but two, in whom no response was excited, a marked agglutination reaction occurred. Local reactions were noted in a few of these cases. Four cases received a single injection of para. C vaccine, and the titres of the sera between the fourteenth and the twenty-first day were 1 in 500, 1 in 800, 1 in 1000, and 1 in 1500 respectively, with an antigen of 1 in 20,000 end-point. Three men received two doses of vaccine at intervals of six to eight days, and after 15 days the response to para. C was 1 in 200, 1 in 300, and 1 in 1500 respectively. Of the three remaining cases one received doses of 500 and 750 million, and two 500 and 1000 million, at an interval of seven days, and the titres of the sera for C agglutinins were 1 in 300, 1 in 100, and 1 in 1100 respectively.

From the above experiments, in which formol-killed paratyphoid C vaccines were used, a definite agglutinin response occurred, but the dosage of the vaccine did not correspond to the agglutinin reaction in any way, as one man after three doses failed to respond, while a second, who received a single inoculation of 250 million, gave a reaction of 1 in 1500.

The Inoculation of Men with the Acid Dextrose Vaccine.

The result of subcutaneous inoculation of the acid dextrose vaccine was observed in 11 cases. In no instance was any local reaction observed, and with one exception, in which a slight para. C reaction was obtained previous to inoculation, the responses excited were feeble. In the case referred to, doses of 250 and 500 million were given, and at the end of three weeks a reaction of 1 in 1500 was obtained. In two cases in which 250 and 500 million bacilli were injected with a 5-day interval, no agglutinin response was

obtained, while in eight instances the men received two or more doses varying from 250 to 1000 million, but only a very feeble agglutination reaction occurred.

It would appear, therefore, that the acid dextrose vaccines, when given subcutaneously in man, fail to excite any marked agglutinin response, and these findings are similar to those made in rabbits when this form of vaccine was used subcutaneously.

The Action of Heat on Human and Rabbit Paratyphoid C Agglutinins.

Seven human para. C antisera were obtained by the subcutaneous injection of paratyphoid C vaccine. Four of these antisera diluted to 1 in 10 with normal saline gave titres of 1 in 800, 1 in 1000, 1 in 1100, and 1 in 1500 respectively. These sera were heated for nine hours at 55° C., and when re-tested it was found that the end-points had fallen to 1 in 200, 1 in 200, 1 in 25, and 1 in 400 respectively. The three remaining para. C antisera, when diluted, were heated at 55° C. for six hours. The end-points of agglutination before heating were 1 in 150, 1 in 300, and 1 in 2000; after heating the end-points had fallen to 1 in 50, 1 in 200, and 1 in 800 respectively. It will be observed that in all cases the paratyphoid C agglutinins were reduced by heat at 55° C. In one experiment in which a sample of human antiserum was heated at 37° C. for nine hours a considerable loss of agglutinin content occurred. Two rabbit antisera were heated along with the human antisera at 55° C. for nine hours, but in one case a slight fall from 1 in 25,000 to 1 in 20,000 occurred, while in the other a fall from 1 in 1500 to 1 in 1250 resulted.

Thus the human paratyphoid C agglutinins appear to be partly thermostable, while the rabbit para. C agglutinin is but slightly affected by heat.

Absorption of Paratyphoid C Agglutinins from Human Sera: Zonular Agglutination.

The sera of four men who had been inoculated subcutaneously with paratyphoid C vaccine, and in whom a good response was excited, were absorbed with emulsion of *B. paratyphoid C*. Before the absorption test was carried out, the titres of the sera were 1 in 800, 1 in 1000, 1 in 1100, and 1 in 1500 respectively. In all four cases complete removal of the paratyphoid C agglutinins resulted, but, as already stated, the thermostability of the para. C agglutinins in man must be fully allowed for, as we found that in the serum saline control tubes the titres of the sera had fallen very considerably.

The absorption tests were carried out with two of these antisera at 37° C., instead of 55° C., but it was found that the agglutinins were completely removed, as occurred at the higher temperature.

Zonular agglutination was noted in 3 of the 35 men inoculated with the para. C vaccines in London, but was not observed in any of our rabbit antisera. The three human sera above referred to gave agglutination readings as follows:—

- (1) 1/25 = 0, 1/50 incomplete, 1/100 to 1/1000 complete, 1/2000 end-point of agglutination.
- (2) 1/25 a trace, 1/50 to 1/100 complete, and 1/1000 end-point of agglutination.
- (3) 1/10 = 0, 1/25 a trace, 1/50 and 1/100 complete, 1/1000 end-point of agglutination.

This phenomenon, which may give rise to fallacies when human antisera are under investigation, has also been referred to by Macadam⁵ while working in Mesopotamia.

The Formation of Paratyphoid B Coagglutinins in the Sera of Persons Inoculated with B. paratyphoid C.

Many of the men who acted as volunteers for these investigations had served in the army and had been inoculated with the triple enterica vaccine. The sera of these men were tested for the presence of typhoid and paratyphoid agglutinins. As a result of these observations the men were divided into two groups: (1) those who gave no reaction, and (2) those in whom a para. B response was present with a para. B antigen of 1-5000 end-point.

Each group was inoculated with a formol-killed paratyphoid C vaccine with doses varying from 250 to 1000 million, and as a result it was found that some men of both groups showed a definite rise in the titre of the para. B agglutinins, while others failed to respond. This para. B agglutinin response was not dependent upon the amount of paratyphoid C vaccine injected.

Para. C Infection in London.

In March, 1920, the *B. paratyphoid C* was grown in blood culture from a case of enterica admitted to St. Thomas's Hospital. On March 18th a girl (M. N.), aged 12 years, was admitted under the care of Dr. C. R. Box, who has kindly permitted us to publish the following notes.

The patient had been ill for two days, suffering from headache, vomiting, and general malaise. She had a rigor immediately preceding admission. On admission the temperature was 102° F. and the pulse 112. No spots were seen. The spleen was enlarged and palpable. On March 21st the temperature reached 104°, and the patient was delirious. Pulse 132. Epistaxis occurred. The temperature lasted for six days after admission, and then fell to subnormal

¹² It must be noted that the para. C antigens prepared by us in London were considerably more sensitive than the typhoid and paratyphoid A and B, and that the results of the C agglutinin response must be considered with due regard to this factor.

and remained so throughout convalescence. Bowels were constipated throughout. A blood culture was made on March 22nd, and the serum was also collected. The blood culture in distilled water grew a Gram-negative motile bacillus, which gave the cultural reactions after seven days' incubation of the B and C bacillus.

The serum was tested on March 22nd and 29th and April 9th. On the first occasion against *B. typhosus* and *B. paratyphosus* A and B no agglutination occurred. The para. C reaction was also tested on the second and third occasions, but no reaction was obtained. This bacillus was not agglutinated by the patient's serum, and when tested with the stock typhoid and paratyphoid A, B, and C antisera gave the following results: T = O, A = O, B = 400%, and C = 9999%. The faeces were examined on four occasions, but the para. C bacillus was not recovered. No history was obtained of any relative having been in the East. The father, a soldier, had been in France, but had never suffered from any enterica-like infection.

Sir Frederick Andrewes has very kindly informed us of a case of para. C infection which occurred at St. Bartholomew's Hospital in 1919, in a man who had been in Mesopotamia. The organism was obtained by blood culture and from the urine. The case, however, was not enterica on clinical evidence.

In conclusion, we offer our thanks to Professor Hirschfeld, who supplied us with the original strain of the *B. paratyphosus* C in 1916, and to our various colleagues in the Balkans who assisted us with our observations, more especially to Captains W. J. Deadman and J. Anderson, R.A.M.C.

SYPHILITIC AORTITIS.

BY S. B. BOYD CAMPBELL, M.C., M.B.,
F.R.C.P. EDIN.,

PHYSICIAN TO OUT-PATIENTS, U.V.F. H. SPITAL; MEDICAL TUTOR,
ROYAL VICTORIA HOSPITAL, BELFAST; LATE MAJOR, R.A.M.C.

WHILE working at the Ulster Volunteer Force Hospital with Dr. J. E. MacIlwaine I was greatly struck by the fact that the Wassermann reaction had been positive in all the cases which showed evidence of an aortic lesion, and I therefore have sent every aortic case met with at pensions boards to have a Wassermann test done. The result showed how important it is to have the blood examined in these cases. Of 25 cases met with in the hospital and at the boards only one gave a negative Wassermann. In this case there was a definite history of rheumatism in a young man and the aortic lesion was a stenosis, thus differing from the syphilitic type, which is never a true stenosis.

The Aetiology of Aortitis.

Any infection may cause aortitis, but the two most common are rheumatic fever and syphilis.

The relative age-incidence in these two diseases is important. In patients below 40 a fair proportion give a history of acute rheumatism. The recruiting for the war showed that a considerable number of aortic lesions had a rheumatic history, while in recent pensions work the great majority of cases point to a specific infection. There is often great difficulty in making a definite diagnosis as to cause, especially where syphilis is denied and a Wassermann test is negative. The post-mortem room is a great teacher, and often upsets a clinical diagnosis, as recent work by Warthin¹ has proved. He has shown that spirochaetes are present in the aorta, aortic valves, and even in the myocardium in a great many cases in which a clinical diagnosis of syphilis had not been made.

The history of rheumatic fever does not exclude the possibility of a coexisting syphilitic lesion. For instance, one of Dr. MacIlwaine's cases in the U.V.F. Hospital gives a history as follows:—

Pensioner, age 33. Rheumatic fever in January, 1916. Discharged from the army in June, 1916, with V.D.H. In June, 1917, he contracted syphilis, and received very inadequate treatment. He was admitted to hospital on Jan. 1st, 1920, with a history of dyspnoea and attacks of sudden, sharp, stabbing pain across the upper part of left chest at intervals varying from two weeks to two months; occasional fainting turns; great feeling of alarm and dread. On examination the heart was found slightly dilated. No increase in cardiac dullness in aortic area. A rough pre-systolic with accentuated first sound in mitral area. B.P. 130—diastolic 96. X ray showed a normal aorta and the "pear-shaped" type of heart. Wassermann was ++ with both Harrison's and Fleming's technique, which positive result, accompanied by pain, dyspnoea, and great depression, led one to suspect an early aortitis in addition to a rheumatic mitral lesion.

Syphilitic Aortitis.

This may be acute or chronic. Cases have been published where well-marked symptoms and signs have

been present within two years of the primary lesion, and one case is on record where the aorta ruptured three months after the primary sore appeared.

In the majority of the cases the aortitis is of a much more chronic nature, and has been latent for a number of years, a sudden exacerbation of the lesion drawing attention to its nature. The majority of cases in the U.V.F. Hospital come into this chronic type. Syphilis has almost always been denied at first, probably due to the fear of loss of pension, and partly to the fact that the men thought they were completely cured because no signs have been seen for many years.

McCrae and Adami² divide arteries into two types—the elastic and the muscular. The aorta and its main branches are of the former type, and this elasticity is of the greatest importance. The aorta receives the first impulse of the blood wave, and is subject to sudden expansion. The elastic fibres, alternating in the media with the muscle fibres, are needed both to prevent undue distension and to bring the vessel back to normal. The change in this middle coat is the important one in syphilis, as it interferes with the contractile and expansile power of the aorta.

The ascending and transverse portion of the aorta are specially susceptible. Some attribute this to the infection being carried by the vasa-vasorum, a theory which also accounts for the frequent involvement of the cerebral arteries. Another theory is that the spread is a lymphatic one, and the first part of the aorta, containing a large number of lymphatics, is most frequently affected. These lymphatics follow the vasa-vasorum, and account for the perivascular infiltration. The change is principally in the media, and is of a chronic inflammatory nature. The tunica adventitia is also involved, producing a connective tissue overgrowth. Intimal changes are secondary and also show a connective tissue hyperplasia. If the weakening of the media is slow, the secondary thickening of the intima counteracts the strain, and the dilatation, if present, is slight; if change in the media is rapid the wall may give way, with formation of an aneurysm. Dilatation may be either local or generalised, and depends partly on the strength of the aortic wall and partly on the internal pressure.

Non-syphilitic arterio-sclerosis differs from the syphilitic type both in distribution and in the coat affected. In the former the patches are usually seen at the orifices of the aortic branches, especially the intercostals, and the change is primarily an intimal one, often with calcareous deposits. In the latter the patches are usually transverse, bear no relationship to emergent vessels, have a puckered appearance, and are usually secondary to a mesaortitis.

The aortitis arising from acute rheumatism, streptococcal infections, and so forth, tends to subside as the primary lesion improves. In syphilis the lesion is progressive unless vigorous antisyphilitic treatment is carried out, and even then it is very refractory to treatment. The aorta is one of the most frequent sites of latent syphilis; Warthin demonstrated active lesions of the aorta in every case of latent syphilis examined.

The lesion usually leads to a dilatation of the aorta, either general or localised. The aortic insufficiency is often attributed to a relative incompetence following the aortic dilatation, but the finding, by the Levaditi method, of spirochaetes in the aortic tissues shows that the insufficiency is an organic one, and, as is usual in syphilis, the change is one of dilatation due to sclerosis of the valves. According to Mix³ syphilis never causes an aortic stenosis.

The specific change may involve the heart muscle, leading to all the symptoms of a myocarditis. Two of the cases that died in the U.V.F. Hospital showed well-marked signs and symptoms of myocarditis. There was a post mortem on one case, and the heart showed myocarditis. Spirochaetes were not looked for, so the specific origin was not proved.

Symptoms.

Early diagnosis of these cases is important. Advanced cases of aortitis, with definite, well-formed aneurysms, show usually the signs and symptoms of the latter. The symptoms and signs of syphilitic aortitis are numerous. They are divided into those due to the actual lesion and those due to pressure, which latter are a late manifestation. Of the early symptoms, pain and dyspnoea are the most important, with, in addition, a peculiar, septic, sallow look, sometimes accompanied by fever.

The patients usually have a feeling of lassitude, depression, and dread. Pain in aortitis is referred to the upper end of the sternum, or beneath it, and is often anginal in character, radiating to the shoulder and arms, and either constant or intermittent. When referred to the apex it is generally due to an accompanying myocarditis. A characteristic feature of the pain is its occurrence during the night. Often there is merely a feeling of oppression about the heart or at the upper end of the sternum (one of the patients who died complained of a sudden "catch" at the root of his neck), and this

is usually accompanied by a feeling of alarm and dread. In certain cases the pain is referred to the epigastrium, and may lead to errors in diagnosis. Pain is a more prominent symptom in some patients than in others, and does not seem to depend entirely on the extent of the aortitis or on the amount of dilatation. The cause of the pain is, according to Sir Clifford Allbutt,⁴ due to an involvement of the aorta, especially just above the sigmoid valves; the undue tension of the fibrous outer coat being the immediate cause.

The dyspnoea usually has a sudden onset without any exciting cause, or occurs after slight exertion or excitement. The chief difficulty is an expiratory one, and, like the pain, it is usually much more marked at night. A sudden onset of dyspnoea in a man above 40, without any definite exciting cause, should always make one suspicious of an aortitis. The peculiar, shallow, septic appearance is striking, and in pensions work I always send such a case to have a Wassermann done, the result in the majority of cases being positive.

Vertigo has not in my experience been a very troublesome symptom. It is attributed by some to a cerebral endarteritis and cerebral ischæmia, by others to perverted impulses from an abnormal aorta being conducted through vagus to the brain.

Physical Signs.

The physical signs are variable; in an early case there may be little or no evidence of an organic lesion of the aorta or heart.

Often the first sign is an accentuation of the second aortic with a diastolic shock on palpation. The second aortic may have a peculiar ringing, musical character, and which extends to the bruit if present. A systolic murmur is often present, and points, not to a stenosis, but to a dilatation of the first part of the aorta. Other physical signs are fullness of the veins of the arms, neck, and shoulders, pointing to some obstruction to venous return; marked visible arterial pulsation in neck; suprasternal pulsation, or pulsation in second right or left interspaces; tracheal tug. Percussion sometimes reveals an increased dullness in aortic areas, but this is often difficult to estimate correctly. The two most important diagnostic tests, however, are the Wassermann test and an X ray of the aorta.

The X ray shows either an increase in density of the shadow or a change in the contour. At least four different types have been described: (1) Elimination of the aortic knob. As the aorta turns to the left and downwards there is a small localised bulging called the "aortic knob." In a dilatation this becomes obliterated and the shadow is continuous. (2) Increase in aortic shadow to right, especially if the heart is not enlarged. (3) Uniform dilatation of the shadow. (4) Definite aneurysms.

In early cases the pathological process is usually limited to the first portion of the aorta, near the aortic valves, and at this stage the vessel is but slightly thickened, giving in an X ray merely a doubtful dilatation of the vessel in this region. As the aortitis develops we get secondary changes such as dilatation and hypertrophy of the heart.

Prognosis and Treatment.

The prognosis is bad, especially if there is any evidence of myocardial involvement; œdema is a very bad sign. The prognosis is often worse with a small than with a large aneurysm. Treatment is mainly anti-syphilitic, though any cardiac symptoms have to be dealt with also. Pot. iodide up to 3ss. doses three times a day, with mercurial inunctions daily, have been used. Novarsenobillon in small doses, 3 gr. every ten days, has also been tried. Most of the cases showed some improvement, but, unfortunately, they are nearly all cases in which syphilis has been present for a number of years, and in consequence are very refractory to treatment.

Conclusions.

1. A Wassermann test should be done in every case of aortic disease.
2. Anginal pain is very frequently associated with an aortitis. The aorta, therefore, in every such case should be thoroughly investigated.
3. Cases of syphilis which are refractory to treatment are often found to have a specific lesion of the aorta.
4. Sudden fatal cases are often found, on post-mortem examination, to have died from a syphilitic aortitis.

I am greatly indebted to Dr. MacIlwaine for his kindness in allowing me to have access to the cases in his wards.

Reviews and Notices of Books.

THE DIAGNOSIS OF NERVOUS DISEASES.

Fifth edition, revised and enlarged. By Sir JAMES PURVES STEWART, K.C.M.G., C.B., M.D., F.R.C.P., Senior Physician to the Westminster Hospital, &c. London: Edward Arnold. 1920. Pp. 584. 30s.

It is some three years or more since we last reviewed Sir James Purves Stewart's text-book of "Diagnosis of Nervous Diseases," which appears now in a fifth edition. Some 10 or 15 new illustrations have been added, and the whole book revised and in part rewritten. It takes its place as an eminently practical compendium of neurological doctrine on both organic and functional sides, characterised by wealth of clinical observation and succinct embodiment of information gleaned from a minute knowledge of neurological literature. It is nothing if not up to date. Limited though its scope may appear, it furnishes the physician and student with a thoroughly sound and extremely readable presentation of neurological knowledge, and its popularity is abundant evidence of its usefulness.

THE NEW PSYCHOLOGY AND ITS RELATION TO LIFE.

By A. G. TANSLEY. London: Allen and Unwin, Ltd. 1920. Pp. 284. 10s. 6d.

SINCE the appearance, now many years ago, of McDougall's "Introduction to Social Psychology" no psychological work more fascinating or more important to the general public has appeared than this. Mr. Tansley endeavours to describe the development and advances of psychology within recent years and its application to the problems of life. The book is based mainly on the writings of Freud, Hart, Jung, and Trotter, but its author has the courage of his convictions and does not hesitate to differ from these authorities where he thinks fit to do so. The result is an exceedingly temperate and thoroughly trustworthy account of present-day psychology, for which a wide circle of readers can be confidently guaranteed. Few psychologists will agree entirely with the writer's views, but none will be found to deny their reasonableness and their sanity. A detailed or technical criticism of them would be out of place here. It will suffice to recommend the book wholeheartedly to the cultured reader who desires a fair presentation of the general position of modern psychology and of its bearing on human life.

NERVOUS AND MENTAL DISEASES.

Ninth edition, thoroughly revised. By ARCHIBALD CHURCH, M.D., Professor of Nervous and Mental Diseases in the Northwestern University Medical School, Chicago, &c.; and FREDERICK PETERSON, M.D., formerly Professor of Psychiatry, Columbia University, &c. London and Philadelphia: W. B. Saunders Company. 1920. With 350 illustrations. Pp. 949. 30s.

WE reviewed the last edition of this well-known American text-book in 1914, commenting favourably on its presentment of the subjects with which it deals, and on its excellent illustrations and format generally. The present edition contains many additional paragraphs derived from war experiences in neurology. We feel, on looking through the volume, that the chapters devoted to hysteria and the neuroses and psychoneuroses generally rather stand in need of modernising, and it appears unnecessary to give the morphology of the hysterical fit in such detail when comparatively little space is allotted to a discussion of the pathogenesis of hysterical symptoms. A section given to hypnotism is included under "Disorders of Sleep." Some of the rarer nervous diseases, such as torsion spasm, tuberosc sclerosis, Alzheimer's disease, encephalitis periaxialis diffusa, do not appear to be mentioned. The volume, nevertheless, will continue, we think, to meet with that favourable reception which it has so long earned.

A MANUAL OF NEURASTHENIA (NERVOUS EXHAUSTION).

By IVO GEIKIE COBB, M.D., M.R.C.S., Neurologist, Ministry of Pensions; formerly Neurologist, Brinnington Section, Second Western General Hospital. London: Baillière, Tindall, and Cox. 1920. Pp. 366. 12s. 6d.

NOTWITHSTANDING the whittling down of the conception of neurasthenia by the disciples of the psycho-analytic school to the results of auto-eroticism in young people, nervous exhaustion exists to a somewhat larger extent than a perusal of their treatises might lead the student to suppose, and will continue to exist when teachers, if ever, have all become psychoanalysts and psychoanalysis is a part of the educational curriculum. If neurasthenia was rife enough in the nineteenth century to be called "American nervousness" or the "English malady" in the eighteenth, it is scarcely likely to have all but vanished in the twentieth. According to Dr. Cobb, it is on the increase. Our terminology or our nosological limit matters little, in fact, so long as we agree that neurasthenia is a syndrome or symptom-complex and not a disease per se. Neurasthenic symptoms of fatigue, mental and physical, with accompanying headache, insomnia, and subjective sensations of all sorts, with or without more obvious gastro-intestinal symptoms, are well known to every practitioner of medicine, who would find a panacea therefor if only to be himself saved from the neurosis. No amount of terminological juggling avails to preserve him from daily contact with neurasthenic reality. To all such we recommend Dr. Cobb's volume. With sound judgment he avoids extremes of ætiological opinion at the same time as he accepts symptomatological facts. And he will be blessed by the worried physician for having devoted almost one-half of his book to treatment.

FUNCTIONAL NERVE DISEASE.

An Epitome of War Experience for the Practitioner. Edited by H. CRICHTON MILLER, M.A., M.D., late Consulting Neurologist, 4th London General Hospital. London: Henry Frowde and Hodder and Stoughton. 1920. Pp. 208. 8s. 6d.

THE appearance of a symposium on "Functional Nerve Disease," contributed mainly by psychologists and psychotherapists, and edited by a psychotherapist, is doubtless a sign of the times. There are many "functional nerve diseases" not so much as mentioned in the volume, which deals almost entirely, one gathers, with hysteria. Though a section is entitled "The Anxiety Factor," Dr. Prideaux, in his contribution, restricts "anxiety neurosis," as opposed to "anxiety hysteria," to cases of physical origin, secondary to organic conditions of the viscera and endocrine glands, and declares they are not amenable to psychotherapy. Other psychopathologists, of course, disdain a somatic origin for any "anxiety" state whatever. "Neurasthenia" and "psychasthenia" do not find much favour with the contributors, but we learn a great deal about "conflict" and "adjustment," about "repression" and "regression." Dr. Crichton Miller, in his introduction, adopts the wholly commendable attitude that the psychical and the physical interact, and that to ignore either at the expense of the other is fatally obscurantist; despite which the work, as a whole, tends to ignore physical ætiology and physical symptomatology. We are not surprised, therefore, to find one contributor stating that "drugs should have no part in psychotherapeutics; tonics are unnecessary, the virtue of valerian is a superstition, a placebo is anathema, and the use of bromides not only rests upon heresy, but is physically and mentally harmful." From such iconoclastic comment let the practitioner turn back to another page, where he will find that "drugs are often of undoubted value; the bromides are used for their sedative effect in conditions of restlessness and general nervous irritability; strychnine and *nox vomica* are of value when exhaustion and fatigue are prominent symptoms," &c. It is but right to state, however, that the editor has been so well aware of the "conflict" among the psychotherapists themselves that he has asked Dr. William

McDougall to make a critical summary in a final chapter, and this has been done with conspicuous fairness. In fact, without this last contribution the practitioner would be in a poor way towards understanding better what the war has really taught the psychologist. Considered individually, the contributions will be scanned with interest by the neurologist, who nevertheless may raise a mild complaint that the title of the book does not give an adequate clue to its contents.

PSYCHO-ANALYSIS.

A Brief Account of the Freudian Theory. By BARBARA LOW, B.A. Introduction by ERNEST JONES, M.D., M.R.C.P. London: George Allen and Unwin, Ltd. 1920. Pp. 187. 5s.

Miss Low's précis of Freudian lore is intended for those who have not time to study original authorities, and it embodies a useful presentment of the subject strictly from the viewpoint of the founder of the theory. The exposition follows lines with which the student of Freudian doctrine is, of course, familiar, and is given in simple language with useful illustrative instances. Miss Low, who is not, apparently, a member of the medical profession, speaks on various pages of "patients treated by myself," and thus the important point is incidentally raised to what extent ignorance of or indifference to psychotherapy on the part of the profession results in patients going to the unqualified for what they want. She repeats the stock tenet of the Freudian that the physician—Miss Low rather avoids the word and speaks almost invariably of the Analyst (with a capital)—must not be teacher, suggestionist, ethical adviser, and so forth, but simply a seeker after the patient's own discovery of himself; yet almost on the same page she talks of the analyst using the influence which he obtains over the patient, of his leading the patient to weave the disentangled threads into a new whole, and so on. The book concludes with a sanguine forecast of the probable social and educational results of psycho-analysis, among which, it seems, are to be numbered the transference of buildings once occupied as prisons into educational institutions, and the removal of repressive law and custom from their action in imposing penalties on impulse-freedom. Children, it appears, even infants, if of opposite sexes, will not share beds with each other, or bathe together, or be dressed or undressed in each other's presence, or, worst of all, sleep with their parents; yet, oddly enough, these will not be so apt to be "over-clean, over-nice, over-proper" in regard to the behaviour of the very young, but will allow them to "play freely with actual dirt of any kind they spontaneously find, and fully express their interest in their own bodily functions."

TREATMENT OF THE NEUROSES.

By ERNEST JONES, M.D., M.R.C.P., President of the British Psycho-analytical Society. London: Baillière, Tindall, and Cox. 1920. Pp. 233. 10s. 6d.

THE greater part of Dr. Ernest Jones's readable volume on the treatment of the neuroses is concerned with hysteria and its handling by the various psychotherapeutic methods at present in vogue—viz., suggestion, including hypnotism, re-education, and psycho-analysis, though physiological measures and the general management of hysterical cases are not ignored. He writes fairly and judiciously of all methods, pointing out their advantages and disadvantages, but deals with psycho-analysis at greater length and with greater persuasiveness than in the case of any of the others. He has rather reversed the position formerly taken up by himself in regard to the treatment of mild cases of psycho-neurosis, apparently holding that they should have the most radical treatment of all—i.e., the psycho-analytic treatment—in order to avoid subsequent relapses and increasing psychotherapeutic difficulty. He has only heard of one case in which another method, the hypnotic, succeeded better than the psycho-analytic. It can thus be maintained that failures in psycho-analytic treatment are the result of insufficient psycho-analysis. Notwithstanding Dr. Jones's able advocacy of the surpassing

advantages of psycho-analytic measures, his argument is unconvincing that as he himself has had experience of the methods and obtained the best results with psycho-analysis it is most to be commended for general use. The physician equally with the psychotherapist must judge for himself which method to pursue, and whether any method can be pursued solely and strictly by itself.

THE NEW PHYSIOLOGY IN SURGICAL AND GENERAL PRACTICE.

Fourth edition, revised and enlarged. By A. RENDLE SHORT, M.D., F.R.C.S., Senior Assistant Surgeon, Bristol Royal Infirmary; Lecturer on Physiology, University of Bristol. Bristol: John Wright and Sons, Ltd. 1920. Pp. 291. 9s. 6d.; paper covers, 7s. 6d.

THE last edition was published just before the war and bore a slightly different title. This edition has undergone considerable transformation, and much of it is new. Into the chapter on "Food Deficiency Diseases" have been incorporated most of the newer observations on the growth factors and on neuritis, scurvy, and rickets. The section on "Researches on Blood" deals in detail with blood transfusion after severe hæmorrhage, with coagulation of the blood as the basis of an exact pathology of hæmophilia, purpura, and hæmorrhagic jaundice, with anaphylaxis, and with the therapeutics of calcium salts. An entirely new chapter on the heart, by Dr. Carey Coombs and Dr. Herapath, is devoted to the polygraph and electro-cardiograph and an analysis of the results obtained therefrom. The chapter on "Surgical Shock" has been entirely rewritten in the light of war experience. Before diagnosing shock, it is considered necessary to exclude or allow for considerable loss of blood, concussion of the central nervous system or thorax, and various forms of toxæmia. In shock the heart is not primarily at fault, the arteries and superficial veins are contracted, and if the blood volume is between 65-70 per cent. of normal, and the blood pressure below 90, the condition is grave. The experimental means of inducing shock-like conditions in animals are described, and useful practical information is given as to the best means for its prevention and treatment. Adrenalin is accounted dangerous; transfusion of saline solution or gum-saline is inferior, both theoretically and in practice, to blood transfusion, which is the best remedial measure in our armamentarium. The recent work on the functions of the stomach and intestines is dwelt upon in connexion with injuries, diseases, and operations on these organs. It would seem "that the colon is not a necessary organ." The remarks on the colon as an organ of absorption raise the whole question of feeding by nutrient enemata. "Feeding with nutrients composed of peptonised milk is sheer starvation, but better results may be obtained with enemata composed of dextrose and long-pancreatised milk."

War surgery and bone-grafting have revived the question of the growth of bone, and the observations of Sir William Macewen as to the regeneration of bone are given some prominence. Whatever view is accepted, the practical point is that, even if bone deprived of periosteum can survive and form a useful graft, the periosteum should always be preserved if possible. The obscure relation between growth of bone, the healing of ununited fractures, and certain endocrine glands is indicated. The necessity of a more extended study of the genital glands and of the endocrines is emphasised. To the surgeon the chapter on the immediate and remote poisoning by chloroform is suggestive and explanatory. The functions of the spinal cord and peripheral nerves are next considered and the diagnosis of lesions discussed. The chapter on localisation of function in the brain has been brought up to date. Both these chapters will prove useful to surgeon and physician alike.

We cordially commend a careful study of this volume to all who wish to keep pace with the modern advances in diagnosis and treatment, as illuminated by the "new physiology," and set forth by one of its most accomplished and earnest students.

SURGICAL TREATMENT.

By J. P. WARBASE, M.D., F.A.C.S. London and Philadelphia: W. B. Saunders Company. 1920. In three volumes. With 2400 illustrations. Vol. II., pp. 829; Vol. III., pp. 861.

A REVIEW of the first volume, which deals with the principles of treatment, operations, infective surgical diseases, and the surgery of bones and joints, was published in THE LANCET of Feb. 1st, 1919. The part at present under review consists of Volume II., which is concerned with regional surgical treatment, and Volume III., covering the special treatment of the intestines, genito-urinary organs, and so forth; a small separate volume contains a combined index to the whole publication, additional to the index provided with each part. The work represents an endeavour to provide the surgeon with an account of all varieties of treatment that apply to all surgical diseases, clearly a very difficult undertaking; yet despite the difficulty of the task the result is on the whole satisfactory.

It is unlikely that any really complete work on such a large subject could be produced, even in three volumes of this size. There are necessarily omissions. For instance, in the chapter dealing with the surgical treatment of hernia, no account is given of the use of the fligree in the repair of specially weakened abdominal walls. Possibly the author regards this as an obsolete operative measure, though he makes several mentions of the use of silver wire as a suture in hernia cases. He considers that it should be replaced by the employment of fascial or other grafts, methods of which he gives only the briefest accounts. But the test of the worth of such a work is whether or no it is of practical use. Will the surgeon engaged in the treatment of any particular case refer to it with confidence? It must be admitted that some sections are inferior to others, and even the best are not entirely complete. On the whole, however, the book has a genuine value, and will be of special use to the surgeon of limited experience, who will find in it helpful descriptions of surgical procedures with which he may not be familiar. If he refer to it for advice concerning matters of which he has a wide practical knowledge he may be disappointed.

There are abundant illustrations, mostly good, much new work is described, and the text is well arranged for easy reference.

AIDS TO ELECTRO-THERAPEUTICS.

By J. MAGNUS REDDING, F.R.C.S. London: Baillière, Tindall, and Cox. 1920. Pp. viii. + 196. 5s. net.

ABOUT one half of this book is devoted to electro-therapeutics. Of the remainder, 47 pages deal with X ray therapeutics, and then follow short chapters on radium, photo-therapy, and electro-diagnosis. The book concludes with an index of treatment. A considerable amount of information is thus conveyed in this small volume. Common forms of apparatus and the methods of using them are described in some detail, while the theory discussed is confined to that necessary to explain the mode of action of X rays and electric currents in the treatment of disease. The chapter on electro-diagnosis deals almost entirely with paralysis due to nerve injury, and much more of it is devoted to the clinical than to the electrical side of the subject. The electrical examination of paralysis due to inflammatory lesions, one of the most important parts of medical electricity, is not considered. The diagram shown in Fig. 2 does not represent the alternating current on the main, and the account in Chapter VIII. conveys the idea that the sinusoidal currents used in medicine differ from those taken from the A.C. main. However, the descriptions are for the most part clear and easy to understand. The book will be of use to those who are reading for the higher examinations in medicine and surgery, and its contents will form a useful résumé of some of the subjects required for the recently established Diploma in Medical Radiology and Electrology.

ADVICE TO CONSUMPTIVES.

Second edition. By NOEL DEAN BARDSWELL, M.V.O., M.D., F.R.C.P., Principal Assistant Medical Officer, Public Health Department, London County Council, and Medical Adviser to the Insurance Committee for the County of London; late Medical Superintendent, King Edward VII. Sanatorium. London: A. and C. Black, Ltd. 1920. Pp. 153. 3s. 6d.

THIS book is prefaced by a short note by the late Dr. C. Theodore Williams. It consists for the most part of a series of lectures given by the author to patients at Midhurst. A methodical turn of mind has induced Dr. Bardswell to keep a note of every question about consumption asked him by his patients, and the work is a classified collection of his answers, written with the authority given by experience, and it contains information of value to that section of the lay public which can afford to follow the advice.

With regard to rest and exercise the author seems, on the whole, to belong to the "active" rather than to the "passive" school, and he believes golf to be the best game that the consumptive can take up when he is completely convalescent. He also considers bathing, especially sea-bathing, as beneficial to most patients. Cycling, too, he regards as permissible for the majority of patients, provided it is made a means to an end, not an end in itself. But cricket, tennis, skiing, and tobogganing are tabooed. Breathing exercises are also recommended, and smokers will be pleased to read that three pipes a day of good mild tobacco may be indulged in, provided there is no weakness of the throat. The managers of sanatoriums, catering rather for the amusement than for the health of their patients, might well study the author's remark that: "To go to a health resort and sit all day in a smoking room, playing cards, is not a good programme for the consumptive in search of health." A specially valuable section of this book is that which deals with emigration; the most important colonies and other places abroad are discussed from the point of view of the prospective consumptive emigrant.

The author's views as to risk of infection show much common sense, and the following lines are typical of his own attitude towards this problem. "For some years I shared a sleeping chalet with a friend who was suffering from somewhat advanced consumption. The chalet, open on three sides, was placed in the garden; our beds were about a yard apart. My day was spent for the most part in the open air, and my life generally was a healthy one. I never felt the least fear of becoming infected under these conditions of close contact. At the same time I should have absolutely declined to work day by day at the same desk with this patient in a stuffy city office."

EARLY ENGLISH MAGIC AND MEDICINE.

A Paper read before the British Academy, Jan. 28th, 1920. By Dr. CHARLES SINGER. London: Humphrey Milford. 1920. Pp. 34. 4s.

ALL researches into early medicine are interesting as showing the foundations of our present knowledge, and the medicine of our British and Anglo-Saxon forefathers should be of especial interest to us. Dr. Singer has collected a wonderful amount of information upon the subject, although, as it happens, a good deal of the ground had already been covered by Dr. J. F. Payne in his first series of FitzPatrick lectures. Dr. Singer distinguishes eight elements which go to make up the medicine of our early forefathers—namely, Greek medicine filtered through Latin; ecclesiastical elements; Salernitan texts; native Teutonic magic and herb lore; Celtic magic; herb lore from Southern Italy; Byzantine magic; Pagan Roman spells. Dr. Singer possesses a wonderful fund of by-ways of knowledge—e.g., he notes in commenting upon Byrhtferd of Ramsey's diagram of the relations of macrocosm to microcosm that the initials of the four cardinal points which are given in Greek, Arcton, Dysis, Anatole, Mesembrios, make the word Adam, and that Adam is called *protoplastos*. This word, says Dr. Singer, is liturgical, and is found in

the Mozarabic liturgy but not in liturgies of later Roman origin. The term *protoplasti*, we may add, is applied to the first men by Tertullian, an African father, and the word may have got into the liturgy through the Moors. Altogether, the paper is well worth reading.

RECENT AMERICAN WORKS ON FOOD AND DIETETICS.

Diet in Health and Disease. By JULIUS FRIEDENWALD, M.D., and JOHN RUHRAH, M.D. Fifth edition, reset. London and Philadelphia: W. B. Saunders Company. 1919. Pp. 919. 25s.—The outstanding feature of this volume is the attention that has been given to the important question of diet in disease, this section occupying rather more than half of the contents. It is preceded by general considerations in regard to the chemistry and physiology of digestion, the various classes of foods, and the factors concerned in the diet of individual cases. The composition of foods is discussed with some detail, and the now familiar unit, the calorie, and the value of foods based on calorific estimates claim full consideration. The accessory food factors come in for attention, whereas in previous editions their importance was not so much in evidence. As we have implied, however, the value of the work rests largely on the adaptation of a dietary to a patient's needs and comfort as set out in a well-written series of chapters on diet in disease. These will form a useful source of reference to the general practitioner.

Bacteriology and Mycology of Foods. By FRED. WILBUR TANNER, M.S., Ph.D. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1919. Pp. 591. 28s.—The subject of foods is not directly reached in this volume until the reader comes to Chapter VI., when the proteins, carbohydrates, and fats are considered. The previous chapters are devoted chiefly to bacteriological technique, including one (Chapter V.) with quite extensive sections on sterilisation and disinfection, and a somewhat elaborate reference to the standardisation of tar acid disinfectants based on what is called the "Hygienic Laboratory phenol coefficient," deduced from a modification of the method established by the researches of THE LANCET Commission on the subject in 1909. "THE LANCET Method" is described as an introduction to the modified method of the Hygienic Laboratory (United States Public Health Service). These chapters are succeeded by sections, amongst others, on water hygiene, milk and milk products, the bacteriology and composition of eggs, meat and meat products, food preservation, and, lastly, epidemiology. The section on eggs is one of the most interesting in the book and bears largely on the question of the diagnosis of the age of the egg and the characteristics shown by the stored egg, pickled egg, and so forth, as manifested by transparency to "candling." The coloured illustrations here are a remarkable feature of the book, in giving a faithful portrayal of the fresh and stale article. We agree with the author that the field of food microbiology is a broad one, but he seems to have encountered some difficulty in keeping up a smooth sequence of events within the limits of this publication.

Milk. By PAUL G. HEINEMAN, Ph.D. W. B. Saunders Company. 1919. Illustrated. Pp. 684. 25s.—Milk would be a difficult subject to exhaust, but the work in front of us is remarkable in its extensive and intensive treatment of all questions connected with the hygienic aspect of milk-supplies. Laboratory work is outlined describing the important methods for carrying out sanitary milk examinations, and the bulk of the subject-matter is based on a series of lectures delivered in the Department of Hygiene and Bacteriology of the University of Chicago. This course deals with the physical and chemical properties of milk, the biology of milk, including bacteriology, and methods of producing, handling, and distributing milk. Whilst an admirable example of compilation, many of the numerous chapters give direct evidence of original work. The references to enzymes, vitamins, and sterilisation show the author's acquaintance with modern work done upon

these subjects by British authors, as, for example, that of Lane Claypon, Starling, Halliburton, Harden, Hewlett, Woodhead, and others. Communications which have appeared in THE LANCET are cited in the copious bibliography at the end of each section, and reference to these will show how high British research stands, where the composition and qualities of milk are in question, making our practical treatment of distribution a scandalous discrepancy with our science. The concluding chapters relate to milk products, including condensed and desiccated milks. The author points out the advantages of dried milk, but appears to have overlooked, when he refers to the shipping of milk powder from one country to another, the troublesome property of the fat in full-cream powders sooner or later becoming rancid. This publication will advance its readers in all modern knowledge concerning milk.

Food: its Composition and Preparation. By MARY T. DOWD and JEAN D. JAMESON. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. Pp. 173. 6s.—The authors of this book are teachers of household science at the Washington Irving High School, New York, and they deal admirably with a subject of capital importance. The physiology and chemistry of foods are described in clear and simple terms, and the chapters on practical matters, the preparation, selection, and cooking of food, should be most serviceable. Science and practice are here well partnered, and there is set out an excellent course of training in regard to the things that nourish us and how to present them attractively, as well as scientifically, for consumption.

Diet Lists of the Presbyterian Hospital, New York. Compiled with notes by HERBERT S. CARTER, A.M., M.D. Second edition. W. B. Saunders Company. 1919. Pp. 165. 6s.—This book affords a useful synopsis of approved diets in pathological conditions. After a consideration of the suitable diets for convalescents, the following series are dealt with: typhoid diets, pneumonia diet, nephritic diet, diet in arterio-sclerosis, gastric diets (including gastric tests), diets for intestinal conditions, diabetic diets, purin-free diets, obesity diets, low calcium diets, convalescent children's diets, followed by a number of miscellaneous recipes in the concluding chapters. Since the compilation is based on the latest studies in all countries of the various subjects entailed, and on the inferences derived therefrom in practice, the book offers a useful source of reference to consultants and practitioners alike.

The Nation's Food. By RAYMOND PEARL, Ph.D., Sc.D., LL.D. W. B. Saunders Company. 1920. Pp. 274. 16s.—The chief interest of this work lies in food statistics, but the copious returns given refer mainly to the position of the United States in regard to these matters. The question of the relation of food imports to food exports, as outlined in Chapters VI., VII., and VIII., invites attention, however, on this side, as well as also Chapter V. on "Total Human Food Production." The book brings out clearly the interdependence of nations on food-supplies, as is instanced in the opening section on "The Food Problem." We find here a food map of Europe showing in diagrammatic form where the shortage of production is. The map is marked in four sections as follows: (1) famine conditions, (2) food shortage approaching famine point, (3) serious food shortage, and (4) sufficient present supply, but future serious. It is interesting to note that England, France, Scandinavia, and Spain are placed in the last category, while Russia, Poland, Serbia, and Armenia come under the first section. The book focuses attention upon very important social and economic food problems affecting the health and well-being of the nations at large, and this collection of statistics will be valued coming from an authority who during the war was chief of the Statistical Division of the United States Food Administration under the control of Mr. H. C. Hoover.

Text-book of Meat Hygiene. By RICHARD EDELMANN, Ph.D. Fourth revised edition by JOHN R. MOHLER, A.M., V.M.D., and ADOLPH EICHHORN, D.V.S. New York and Philadelphia: Lea and Febiger; London:

J. and A. Churchill. 1919. With 161 illustrations and 5 coloured plates. Pp. 472. 24s.—Our impression of the value of this volume to those engaged on meat inspection, expressed in a review of the previous edition, which appeared in THE LANCET of March 29th, 1913, receives answer in the fact of a fourth revised edition being issued. The rules and regulations governing meat inspection of the Bureau of Animal Industry of the United States form largely the text of the chapters, and these rules are a model for other nations. Laboratory methods are clearly described, and, generally speaking, this revision may claim to present the latest knowledge on modern developments of meat hygiene. There is no subject of greater importance to the community than the advanced study of meat hygiene with the view of letting free to that community only sound and wholesome animal food. This book fulfils a well-defined purpose.

JOURNALS.

Tubercle. A Monthly Journal Devoted to all Aspects of Tuberculosis. Vol. I., No. 9. June, 1920.—The *Rôle of Heliotherapy in Surgical Tuberculosis* is the title of a lecture by Sir Henry Gauvain, which was delivered at Alton to post-graduates, and gives a general survey of the use of sunlight with a well-balanced estimate of its value. In contradiction of Rollier and others, the author assigns the first place to general and local conservative methods and puts insolation among adjuvant means with X rays and vaccines. The psychological value of sunlight is known to all, though some persons are much more affected than others, and this value is no doubt increased when the solar radiation is intentionally directed to therapeutic ends. The local or direct action of sunlight appears to be due to short-waved rays of low penetrative power and is thus limited to the superficial structures; it is potent as a bactericide chiefly in lupus and similar conditions. This direct effect is obtainable in any patient. Not so is the remote or indirect effect which depends not only on the qualities of the radiation, but on the physiological responses of the tissues, the most obvious of which is pigmentation. This factor is regarded as enormously important, for in some unexplained way pigmentation is so closely associated with recovery that it becomes a measure of resisting power and a sign of great prognostic significance. Heliotherapy is also the subject of a series of abstracts in this number. Dr. Holmboe, of Mesnali, Norway, has combined the method with sanatorium treatment of pulmonary tuberculosis without interfering with the ordinary routine, and is satisfied that under careful dosage the patients benefited. No case suffered any harm, and high fever is almost the only contra-indication. The writer aims at pigment formation, following Rollier, who believes that pigment acts as a transformer of ultra-violet rays into others of greater penetrating power. Reyn, on the contrary, avoids pigmentation as far as possible, because he regards pigment as a barrier converting the beneficial long waves into the short-waved ultra-violet rays, but it is difficult to believe the result of a normal physiological process can be other than useful to the organism.

In a review of the annual report of the Canadian Association for the Prevention of Tuberculosis, attention is drawn to Dr. Dobbie's views on the vitally important question of prevention. It is easy enough to say that the surest way of suppressing tubercle would be to segregate all infectious cases, but we are dealing with human beings, not animals. Dr. Dobbie has a more excellent way. He approaches the matter from the standpoint of the susceptible subjects, dividing them into three groups in order of susceptibility: (1) infants under 3; (2) children over 3; and (3) adults. Infants should be totally isolated from any infective source, be this mother, father, or any other. Surely this course of procedure should not meet irreconcilable opposition. In the case of children over 3 Dr. Dobbie thinks isolation neither necessary nor desirable, since infection must occur sooner or later, and the main thing is to avoid massive infection while immunity is being developed. Lastly, the case of adults needs but little care, the great majority being already infected, but when advanced cases are a danger to others they should be compulsorily detained. There is much to be commended in this scheme.

Dr. Esther Carling contributes a report on cases of Pulmonary Tubercle treated by Artificial Pneumothorax, and this procedure is the subject of a long series of abstracts. The work of the Community Health Station at Framingham, Mass., U.S.A., is the subject of two articles. This great experiment in public health has now been carried on for more than three years and its results will be watched with increasing interest.

THE LANCET.

LONDON: SATURDAY, JULY 3, 1920.

The Annual Meeting of the British Medical Association.

THE Annual Meeting of the British Medical Association is proving a great success: it will have terminated before these words are read, but with its admirable setting at Cambridge, with a President so famous on the highest scientific planes that his official post confers dignity on the body over which he presides, and with a programme in which hard business, high thinking, and judicious levity are aptly combined, there can be no doubt that the meeting will end as it has begun, and form a memorable occasion.

We publish this week a summary of the proceedings at the four sessions of the Representative Body, which lasted four days. From these it will be seen how various were the professional subjects discussed, and how careful the Representatives were in their consideration of the mass of recommendations made by the Council, and of the riders and amendments arising thereout. This thoughtful attitude was well marked in the way in which the Representative Meeting dealt with the Interim Reports to the Ministry of Health from the Consultative Councils. The door was here open to all sorts of mistakes by way of too hasty criticism of avowedly interim documents. It is true that the meeting had before it a careful Report from the Ministry of Health Committee of the Association, but even with such guidance there were many opportunities for allotting general praise or general blame to prominent features of schemes which have been put forward as ideals for trial, and not as concrete proposals for imminent legislation. The opportunities were not taken, but a vote of real appreciation of the Consultative Councils' activities was recorded in terms that will afford Lord DAWSON, as the first chairman of the English Consultative Council, whose findings were under particular consideration, legitimate gratification, and, what is far more important, practical support for the future. The work of these Councils has yet to be done, and the demeanour of reserve was correct, but that it is not habitual with the Representative Body when expressing opinions is well shown by the resolutions passed where all the circumstances could be judged. The Representatives had no hesitation whatever in saying that, whether it were legally or officially inconvenient or no, the contents of remedies administered by the medical profession must be disclosed to the profession; while they turned down the idea of a whole-time State service of medicine uncompromisingly.

The scientific work of the Association was inaugurated nobly by the Presidential Address, appearing substantially at the front of our issue, wherein Sir CLIFFORD ALLBUTT discussed the part that should be played by the universities in the improvement of medical practice and the further-

ance of medical research. He brought the history of the great seats of learning, the lessons of liberal education in the past and present, and his intimate knowledge of the medical profession as student, practitioner, psychologist, and professor, all to bear upon his theme; and by showing how directly the treatment of the sick is enlightened and fortified by, even if not based upon the ancillary sciences, he proved that no university can have a nobler faculty than that of medicine, and that no calling demands more universality in its education than the calling of the doctor.

The Teaching of Obstetrics.

AT the last meeting of the General Medical Council, a report on practical midwifery was presented by the Education Committee, and a general discussion took place upon this important subject. It is of course common knowledge that at many of the medical schools the regulations of the Council with regard to the proper teaching of this subject are not being carried out, and that by the major number of the examining bodies they are not insisted upon. At the present time we believe it is only the universities of Oxford and Cambridge which require that the student shall actually receive practical instruction in lying-in wards before presenting himself for his examination in midwifery. Other examining bodies only require attendance on a certain number of cases in the extern maternity department, where the teaching received by the student is often very imperfect, carried out as it is by junior residents or occasionally by a rather more senior registrar. If the teaching of practical midwifery is to be put upon a proper basis the examining bodies must be persuaded to alter their regulations and to require attendance and adequate instruction for every student in a properly equipped intern department; and in order that this change may be brought about it is imperative for the other members of the teaching staffs of the medical schools to recognise that the importance of practical midwifery for the average practitioner is just as great as that of practical medicine and surgery. At the present time the number of the beds, less than one-twentieth, allotted to lying-in cases in the principal London hospitals is absurdly small, and it is impossible in most cases for the obstetric physicians or surgeons, always in a numerical minority, to persuade their colleagues to hand over to their charge the beds necessary for the proper teaching of their subject. The right balance will hardly be struck until all the examining bodies make the bedside teaching of midwifery compulsory.

It is, we fear, little use for the General Medical Council to make recommendations which the examining bodies ignore, and which, therefore, the medical schools do not carry out. The teaching of practical midwifery to medical students in London at the present time is extremely inadequate, as the report from the Obstetrics Section of the Royal Society of Medicine on the teaching of obstetrics and gynaecology to medical students clearly shows. This report has been circulated, we believe, to all the medical schools, but, so far as we are aware, no action has been taken. It is hardly reasonable to hope that physicians or surgeons will give up beds until they are required to do so by the regulations of the examining bodies, while in the present state of

hospital finances the managing committees cannot be expected to enlarge their institutions for this purpose. Still, it is impossible to reiterate too strongly that the teaching of midwifery will never be on a satisfactory basis until all the examining bodies insist upon proper practical instruction being given, and until every medical school has attached to it a complete obstetric department, officered by men adequately trained for teaching and supplied with the necessary number of beds and the requisite laboratories and other requirements not only for teaching but also for research. At the moment infant welfare is in the ascendant, but given a certain limited supply of money and effort it might be better to spend these upon the mothers rather than upon attempting to keep alive unhealthy and delicate children whose ill-health and delicacy are in many cases due to the lack of proper care of the mother before and at the time of her confinement. Of course, any properly equipped obstetric department will have associated with it an infant-welfare centre, and until such departments are instituted in the metropolis the teaching of obstetric medicine, including antenatal care, will remain unsatisfactory.

Consultant Medical Service on a Graduated Income Basis.

DETAILS have recently been made public of an important experiment in providing a complete medical service for the staff and workpeople of a London business house. The experiment was inaugurated on a small scale some time ago by Messrs. THOMAS DE LA RUE AND CO., Ltd., and has met with such success at their hands that the Company is now commending it to other employers. The kernel of the matter is that a number of consulting physicians and surgeons have agreed to treat privately at reduced fees patients sent to them by the Company, the fees to be based upon what is described as "adjusted income." This includes private means as well as salary, one-fifth of the total being deducted on account of a wife and a further one-tenth on account of each child or other dependant member of the household. The fees payable vary from 10 to 60 per cent. of the norm for operations and from 25 to 100 per cent. in the case of consultations and medical treatment, a minimum of a guinea for a single visit being payable in all cases. In order to ensure that cases are not sent to the consultant staff without due cause, a certificate is required in each case from the Company's medical adviser, the patient then going on to the consultant with a voucher stating the proportion of the normal medical fee payable by him. The Company thus constitutes itself as almoner to private practice, relieving the consultant of the onus of making tiresome inquiries. A further proposal is now made with a view to the provision of a great central nursing home for the reception of employees from a number of business houses at reduced fees, it being suggested that a private institution of this kind with a large number of beds could be run at considerably less expense than at present prevails in the smaller nursing homes now available. Mr. STUART DE LA RUE, who holds an official position on the King's Fund and on the Hospital Sunday Fund, states that his scheme has so far received the whole-hearted support of the medical profession.

The Promise of Peat Potentials.

THE scarcity of fuel concerns us all, and, should it get acute, may well give rise to ill-health. This consideration adds a medical interest to a lecture delivered by Professor PIERCE F. PURCELL on the Peat Resources of Ireland before the Royal Dublin Society, and now published by the Fuel Research Board (Department of Scientific and Industrial Research). The story is mainly technical, but conveys clear and simple lessons to the intelligent reader. In a prefatory note the Director of Fuel Research, Sir GEORGE BEILBY, points to the revival of interest in the question of peat now that there is an admitted scarcity of other kinds of fuel. The peat industry requires wide knowledge, perseverance, and a strong financial backing, for its development is capricious, and fortunes have been lost in it. Professor PURCELL points out that though 98 per cent. of the coal used was imported into Ireland in pre-war times, the supply was ample and the price relatively low, but these happy conditions will return no more. The supply is now reduced, while the price is beyond the means of most, and this reduction of fuel and shortage of food helped to increase the severity of the epidemics of influenza which prevailed in the coast towns of Ireland two years ago. It has been claimed that there is less illness in those houses where peat is employed as a fuel. There is certainly less smoke and dirt produced by the combustion of peat, while bread baked by such fuel holds among the peasantry the highest reputation.

The physical properties of peat are remarkable. The material may contain anything up to 95 per cent. of water and still remain a solid. It is interesting to contrast this with milk containing 12.5 per cent. of solids and 87.5 per cent. of water, in spite of which it is a mobile fluid. Most meats contain 70 per cent. of water, but in such cases the water must clearly be in a kind of combination with tissue or substance, although easily liberated from it by heating or cooking. Evidently the rôle and exact location of water in animal and vegetable tissues calls for investigation. Water is the main trouble in peat. In order to produce one ton of air-dried peat it would be necessary to handle 15 tons of raw peat containing 95 per cent. of water. The net calorific value of dried peat, according to Professor PURCELL, would be 6000 to 7000 B.T.U., and reckoning the average heating value of coal at from 12,000 to 14,000 B.T.U. this means that two tons of dried peat are the equivalent of one ton of coal. It should be noted, however, that the mineral matter in peat averages only 4 per cent., while coal may contain anything up to 20 per cent.

The real problem about peat is the economic elimination of its obstinate water contents. Professor PURCELL's interesting lecture discloses the possibilities of utilising important national reserves to supply our fuel needs, and raises questions of the greatest importance when we consider the vast peat areas in the country hitherto practically untouched. The peat deposits in Ireland, or bogs, as they are commonly termed, cover no less than one-seventh of the area of the country, and already form the entire fuel supply of 62 per cent. of the farming industry. It is to be hoped that this illuminating lecture will so stimulate the coöperation of science and industry as to bring a fund of fuel to the prompt disposal of a necessitous community.

Annotations.

"Ne quid nimis."

THE "TOMES" COLLECTION.

THE Museum of the Royal College of Surgeons of England has received from Sir Charles Tomes, F.R.S., a gift of great scientific value—namely, the microscopic preparations of teeth made by the donor and by the donor's father, the late Sir John Tomes, F.R.S. The collection thus presented consists of more than 1300 specimens of ground or otherwise prepared sections of the teeth of vertebrate animals. The dental anatomy of all forms of mammalian teeth is depicted more fully than in any other collection. The "Tomes" collection, which thus becomes accessible at the Royal College of Surgeons to all students of dental anatomy, will prove of the utmost use to those who are investigating problems in dental structure. Many of the specimens used by Sir Richard Owen in the preparation of his "Odontography" are also preserved in the Museum of the College. The oldest microscopic preparations in the College collection are those made by Hewson in the later part of the eighteenth century.

INDIVIDUAL COUNTY SCHEMES OF MEDICAL SERVICE.

A SIGN of the increasing interest in a better organisation of medical service throughout the country is the effort being made by various counties to formulate medical schemes for local use. Among the most progressive counties in this respect is Gloucestershire, whose County Council reviewed the situation early in 1918 and outlined a scheme, modified in 1919, which has now received the approval of the Ministry of Health. Some 50 "out-stations" will be provided, each to cover a radius of about three miles. The out-stations will be provided and equipped by the County Council primarily for examination and treatment in connexion with venereal disease, tuberculosis, ex-Service cases, school, maternity, child-welfare, and other clinics, for which provision has been made, or may in the future be made, at the public expense. They may also be used by the medical officers for other patients by arrangement with the County Council. Besides the regular staff, consisting of local practitioners, there will be consultants—the visiting staff of the general hospital, and the tuberculosis and venereal disease officer of the County Council—a district nurse, a masseur, and a V.D. orderly and nurse. The out-stations will be opened weekly for attendance by the medical officer, periodically for attendance by consultants, as often as may be necessary for intermediate treatment by the nursing staff, and at such other times as are convenient to the medical officer for seeing his own patients and hospital cases. An ambulance service is also proposed. The expenses will be paid partly by the County Council direct, and partly by the hospital out of sums provided by the County Council. After the first year the advisability of rearranging the scale of payments on a case or attendance basis will be considered in the light of the experience gained. It will be seen that the proposals of the Gloucestershire County Council coincide in important respects with those formulated by the Consultative Council on Medical and Allied Services, which quotes the scheme in its interim report, and the results of their practical application will be watched with the keenest interest by the whole country. The county of Cheshire appears specially alive to the need for a more efficient supply of the ancillary services, and has just issued a statement, prepared by the Local Medical and Panel Committee, of the provision made for diphtheria antitoxin, vaccines, diagnostic and other clinical facilities for the use of the general practitioner. The facilities for pathological diagnosis of venereal diseases, tuberculosis, diphtheria, typhoid fever, *B. coli* infections, dysentery, C.S.F., and malaria available for each rural or urban district are detailed in tabular form. The nearest places where

treatment in the form of arsenic injections, antitoxin, vaccines, serums, and oxygen can be obtained are indicated, as are also the districts in which nursing for ophthalmia neonatorum, influenza, pneumonia, and measles is at present available. Of the home counties, one or two are making special efforts to enhance their already established reputations for infant welfare work. Sussex has recently shown its approval of the sanatorium treatment of tuberculosis by sanctioning the purchase and conversion of two large private estates for this purpose at a cost of some £70,000. The London County Council has established a network of clinics for venereal disease, while the Portsmouth district is making a special effort to cope with this problem on even more vigorous lines. Concentration on one special problem by a local authority, pending the entire reorganisation of the medical services of the country, is hardly less desirable than a trial on a small scale of more general changes; both experiments should be productive of useful results. The value of sanatorium treatment, the effect of the establishment of lying-in hospitals on maternal and infant welfare, the best line of attack against venereal disease—all these are problems the solution of which might be worked out regionally by observation and experiment before huge sums of money are spent simultaneously throughout the kingdom. At the same time, there must be no delay in providing all strata of the community with those medical services hitherto enjoyed only by the rich and, in urban districts, the poor.

HIPPOCRATIC FINGERS.

IN a communication made to the Society of Medical Science at Milan,¹ Dr. Vittorio Ronchetti described the case of a girl, 11 years of age, who died in the Ospedale Maggiore from extensive amyloid degeneration of the liver and ascites following a tuberculous spondylitis, and who showed to a marked degree the so-called Hippocratic or drumstick fingers. At the autopsy, besides the amyloid infiltration of the liver and spleen there were a few scattered sclerosing foci of tubercle at the apices of the lungs, the largest being the size of a pea, some fibrocaseous nodules in the glands at the hilus, and dorsal kyphosis from old Pott's disease. There was neither pulmonary cavitation nor bronchiectasis, nor any miliary tubercle. Dr. Ronchetti draws attention to an interesting fact in this case, not easy of explanation—namely, the coincidence of extensive visceral amyloid disease (the liver weighing 2500 g. and the spleen 150 g.) in comparison with the scantiness of tuberculous lesions; that the few bacilli present immobilised in cicatricial tissue or circumscribed in fibrocaseous foci, encapsuled and semi-calcified and incapable of becoming sufficiently active to produce any miliary diffusion, should have acted as possible causative agents of such intense amyloid degeneration. He expresses his inability to give any adequate solution, but pertinently asks whether amyloid degeneration once started may not be able to persist and progress even though the primary disease which determined its origin becomes extinct or reduced to an infinitesimal degree. The condition of the fingers, which must be distinguished from the hypertrophic pulmonic osteoarthropathy of Marie, is also little capable of definite explanation. Its pulmonic origin can no longer be accepted, at least not univocally, and, moreover, neither the existence of broncho-pulmonary or pleuritic disease, nor the production of putrid substances in the organism can represent the only and exclusive cause, since there are many cases of empyema, bronchiectasis, and tuberculous cavitation in which it is entirely absent, and it is not easy to understand why it is frequent in bronchiectasis and rare in tuberculous vomicae, nor why it should be very common in congenital heart disease and absent in acquired morbus cordis, even after long periods of failing compensation. Dr. Ronchetti states that this is the first time he has met with this condition in amyloid disease of the liver,

¹ Atti della Società Lombarda di Scienze, Mediche e Biologiche, vol. viii., Fasc. 3-4, June 27th, 1919.

and for an explanation falls back on the theory of Ferrio, who attributes it to reflex vaso-motor action causing disturbance of circulation and chronic stasis. A curious fact noted by him is that he has seen it disappear in a case of empyema with thoracotomy and the formation of a pleuro-pulmonary fistula after the patient got well. It is many centuries since the Father of Medicine described *οι ὀνυχες περιτεταμέναι* as diagnostic of empyema, but we have yet much to learn about them.

SURGERY ON THE MOVIES.

RECENT improvement in the reproduction on the film of surgical procedures has been rapid. By means of powerful arc lamps it is now practicable to produce films showing all the details of an intricate operation. At the recent demonstration held under the auspices of the Fellowship of Medicine at the House of the Royal Society of Medicine films were exhibited showing the application of the kinema to the various branches of medicine, surgery, and odontology. The value of such films for teaching and demonstration purposes, especially for post-graduate work, was apparent to all. From a description in print it is not easy to follow all the intricacies of such an operation as an inlay bone-graft, but on the kinema every detail is seen as clearly by the spectators as by the surgeon and his assistants at the actual operation. Particulars of a further series of short film demonstrations, to be given on Monday and Friday afternoons at 5.30 P.M., will be found in our Medical Diary. We warmly commend these demonstrations to all who wish to keep in touch with present-day technique.

HÆMOPHILIA IN WOMEN.

A NEW interest has been aroused in the subject of hæmophilia by the work of H. W. C. Vines, who has shown¹ that the condition can be temporarily alleviated by the production of a slight anaphylactic shock in the patient. Although this cannot be used as an emergency procedure, an extended use of blood transfusion has placed in our hands the means of at once arresting hæmorrhage and of replacing the lost blood. The anaphylactic shock method of treatment has now made it possible to perform upon a hæmophiliac, during the period of remission of the disease, any surgical operation that may be necessary without fear of hæmorrhage. The pathology of hæmophilia remains obscure, and all that it is possible to say is that the coagulation time of the blood is so much lengthened that no clot will form upon a wounded surface; which constituent of the blood is deficient remains a matter for speculation. It was not until the beginning of the nineteenth century that hæmophilia was described as a clinical entity, but already by 1820 enough evidence had accumulated for Nasse, professor of medicine at Bonn, to state that males alone were affected and that the disease was transmitted through apparently normal females mated with normal males. This view of the sex-limited character of the disease has been generally accepted since that time, but the rule has, nevertheless, frequently been challenged. The best general account of hæmophilia in English, with special reference to its manner of inheritance, was published by Bulloch and Fildes in Parts V. and VI. of the "Treasury of Human Inheritance," a very valuable collection of monographs issued by the Galton Eugenics Laboratory in 1911. These authors came to the conclusion that none of the recorded cases of hæmophilia in women would bear analysis, since the statements were unsupported by adequate evidence. The whole literature of the subject, numbering 911 references, was collected by them, and it might have been thought that the question was closed. Since then, however, cases of supposed hæmophilia in women have been reported and this has led to a further interesting contribution to the literature by Dr. Constantine Bucura, of Vienna, in his "Hämophilie beim Weibe."² Dr. Bucura has collected 202 alleged

cases and has subjected them to a critical examination. He finds that almost every known condition in which bleeding, in one form or another, is a feature, has been confused with hæmophilia. The majority of the cases have presented some abnormal hæmorrhage of gynæcological origin and this has been accepted as a manifestation of true hæmophilia, though presenting none of the features which distinguish the disease in the male. Bleedings from the female genital organs are, as Dr. Bucura points out, often difficult to explain. Menstrual blood is deficient in some of the constituents of normal blood, so that normal menstruation amounts to a local hæmophilia of the parts; the balance of the processes involved is easily upset and abnormal hæmorrhage may result, but this does not justify the inclusion of such cases among true hæmophiliacs. There is only one final pathological test for true hæmophilia and that is the measurement of the coagulation time of the blood in the general circulation during a period of hæmorrhage. In true hæmophilia this is increased six or seven times, a degree incomparably greater than is found in any other hæmorrhagic disease. Dr. Bucura finds that no authentic case of hæmophilia in a female has yet been recorded. His conclusions, though negative, are none the less valuable and constitute an authoritative confirmation of the views expressed by Bulloch and Fildes nine years ago.

TYPHUS IN POLAND.

THE serious increase of typhus in Eastern Europe has given rise to an appeal for funds to send a completely equipped unit to cope with the 250,000 cases of typhus at present known to be actually occurring in Poland alone. The signatories include the Bishop of London, Cardinal Bourne, the Chief Rabbi, Lord Treowen, Lord Stuart of Wortley, Sir Arthur Stanley, Mr. T. P. O'Connor, and, among medical men, Sir Humphry Rolleston, Sir James Cantlie, Dr. William Hunter, and Dr. J. C. McClure. We have already pointed out¹ that the westward spread of typhus epidemics is a matter of grave concern to the rest of Europe and can only be prevented by energetic action. The endemic prevalence of typhus in Poland, the nature of the conditions likely to cause its spread, and the proposed measures for its eradication were considered in the Report of the Inter-Allied Medical Commission to Poland, presented to the League of Red Cross Societies in October, 1919. The excellent proposals of the newly established Ministry of Public Health in Poland were also recorded in the report, and suggestions were made for the development of the Polish Red Cross Society, under whose auspices the present appeal is issued. Donations should be sent to the Princess Sapiéha, 45, Grosvenor-square, London, W. 1.

THE SYNDROME OF THE GENICULATE GANGLION.

AT a meeting of the Société Médical des Hôpitaux of Paris, M. A. Souques reported a case of a rare and little-known syndrome, characterised by zona of the external ear, facial paralysis, and auditory troubles on the same side, which he termed "the syndrome of the geniculate ganglion." On Jan. 15th a woman felt severe shooting pains in the right external ear and retro-auricular region. She had at the same time headache and malaise. On the 19th she found that the right side of her face was paralysed and that the ear was red and swollen and showed some "little buttons." Almost at the same time as the pains began, three or four vesicles appeared on the upper surface of the anterior half of the tongue. On examination on Jan. 30th there was complete paralysis of the facial nerve, which gave no reaction to the faradic or galvanic current. There were three groups of fading herpetic vesicles—in the antihelix, concha, and fossa of the antihelix. On the tongue were vestiges of vesicles. The pains which had preceded and accompanied the eruption had disappeared and there was no anæsthesia, but pain was provoked on pressure on the right half of the face. Taste for salt and sugar was diminished

¹ THE LANCET, 1919, ii., 741.

on the right side of the anterior half of the tongue. The patient had not noticed any auditory symptoms, but marked loss of hearing was found on the right side. All these symptoms can be explained by inflammation of the geniculate ganglion. It is now recognised that, like the spinal nerves, the facial is a mixed nerve, and that this ganglion corresponds to the ganglia on the posterior roots of the spinal nerves. The sensory root of the facial is the intermediary nerve of Wrisberg, and the sensory branches are the great and little superficial petrosal nerves and the chorda tympani, which is the nerve of taste in the anterior portion of the tongue. An American neurologist, Dr. J. Ramsay Hunt, has exhaustively described the various forms of herpes zoster due to inflammation of the ganglia of the cranial nerves. He has thus mapped out the cutaneous distribution of the facial nerve in cases of inflammation of the geniculate ganglion: the concha, part of the antihelix, the fossa of the antihelix, and the summit of the antitragus. The connexion of the ganglion with the facial nerve explains the propagation of inflammation from the one to the other and the facial paralysis. Similarly, the proximity of the auditory nerve explains the auditory symptoms. However, direct affection of the peripheral ganglia of the auditory nerve (the ganglia of Scarpa and Corti) cannot be excluded. It is well known that the virus of zoster often attacks several ganglia. There may also be zona of the second and third cervical nerves, as there was in a case shown by M. Souques at the Société de Neurologie. The hyperæsthesia of the face and the pain behind the ear, in the case related above, suggest that either the sensory distribution of the facial is more extensive than has been stated, or that other ganglia were affected. A knowledge of the syndrome of the geniculate ganglion, complete or incomplete (zona of the ear alone or with facial paralysis), is of great practical importance. It may explain certain cases of facial paralysis the cause of which has escaped detection. The presence of pain in a case of facial paralysis would suggest this origin. M. Souques is disposed to think that the prognosis of this form of facial paralysis is better than that of other forms, but admits that his experience of it is very limited.

THE CONTRIBUTION OF VULPIUS TO ORTHOPÆDICS.

Professor Vulpius, of Heidelberg, has a more than European reputation as an orthopædic surgeon, which has been earned by good work done in the specialty. Probably he is best known by his publications on tendon-transference and cognate procedures. Although Nicoladoni first introduced the treatment of the deformities resulting from anterior poliomyelitis by transferring the insertion of an over-acting tendon to that of one which is hopelessly paralysed, he did not live to pursue the subject far. To Vulpius belongs the credit of being a leader in the investigation and proof of the applicability of the method, and if at one time it may have seemed that his enthusiasm outran his judgment, yet a good deal was learnt from the wide scope of his labours in tenoplasty. He has now published in a pamphlet of 80 pages¹ the conclusions which are the outcome of his 25 years' practice as an orthopædic surgeon, together with a review of the history, development, and scope of the specialty and the means best suited to carry out its aims. In a series of short essays he defines the lines upon which the treatment of the most important deformities and joint and bone diseases should be conducted. All these chapters are worthy the perusal of everyone who has to deal with orthopædic problems. Orthopædic surgery, which at first was limited to the instrumental treatment of deformities, took on fresh growth when subcutaneous tenotomy was introduced, seemed likely to be swallowed up by general surgery when Lister widened the field of treatment by operative means, but had been mostly reconquered by specialism ere the beginning of the war.

The experiences of the war led to a surprising extension of the application of orthopædic methods and induced many of our younger surgeons to study and practise them. Some years ago a great step in advance was taken in Germany when a census of cripples was made and the profession and public were startled to find how much cripple treatment had been overlooked and what a great expansion of means of cure was necessary to cope with the problem. There is crying want of such a census in the United Kingdom, and it is to be hoped that the Ministry of Health will undertake the task as an essential to the organisation of preventive and curative measures. The treatment of cripples of all sorts—tuberculous, paralytic, congenital, rachitic, and others—needs special institutions, specially trained surgeons, special apparatus, and much time. The problems of the pre-war period are still waiting to be solved, and to them has been added the burden of war cripples, including amputees. The need of improvement in artificial limbs calls for the collaboration of the orthopædic surgeon, the engineer, and the limb-maker. It can easily be demonstrated that the early and thorough treatment of the nation's cripples will pay for itself in the resulting improved earning capacity of the patients. There is need of many properly equipped orthopædic hospitals, preferably in the country, where all the most recent methods of diagnosis and treatment would be available. Not only for the pauper are such institutions wanted, but also for those of moderate means, since the greatly increased cost of up-to-date treatment bids fair to put it beyond the reach of all but the very poor or the very rich.

CARE AND AFTER-CARE IN TUBERCULOSIS.

In a leading article on Tuberculosis and Residence, which appeared in our issue of Feb. 21st, we discussed some of the economic difficulties in the efficient treatment of a disease so ubiquitous as tuberculosis. The paper under the title of this annotation read by Dr. Stanley Tinker to the Tuberculosis Congress at Leeds was a further practical contribution to the problem of how to make sanatorium treatment more permanently beneficial.¹ Sanatorium treatment fails for two reasons: bad selection of cases and failure to maintain the improved health obtained during absence from home. The former is simply a matter of wise and unbiassed administration. The latter is a huge, and so far unsolved, problem for which after-care committees have been formed and immense and costly settlements are proposed. Care committees are undoubtedly doing good work, but their outlook is, for the most part, too limited, and they are hampered by lack of funds. The proposal to send consumptives to labour colonies to be established for them in healthy country districts, where all the conditions would be conducive to the continued amelioration begun at the sanatorium, would be, as Dr. Tinker says, ideal if it were practical. The Government has promised to create ten such settlements for 200 to 250 men at a cost of £1,000,000. But to provide for the tuberculous sailors and soldiers alone in this way would cost 200 millions, and estimating the civilian tuberculous as low as 200,000, another 1000 million pounds would be required for a complete scheme. "To remove the cases as they occur and to transport them into ideal villages is but to play with the very fringe of the subject." There must, in the first place, be more thorough dealing with the sources of the disease by municipal authorities, and Dr. Tinker thinks that it should be a principal duty of care committees to stir up public opinion and press the borough councils (and the Government?) to do their duty. He rightly says that it is not necessary to wait till the housing problem is dealt with. It is not so much the houses themselves as the dirtiness, ignorance, alcoholism, and other remediable factors associated with industrial areas which are the cause of tuberculosis. Dr. Tinker's alternative to newly created tuberculosis industrial settlements is to leave the consumptives in their homes, but provide within easy reach special workshops where hours.

¹ Medical Officer, June 12th.

ventilation, meal-times, and other conditions are suited to the capacity of the persons employed.

A scheme on these lines is being inaugurated in Wimbledon for the employment of discharged tuberculous sailors and soldiers. The workshops will consist of two parts—one for training and one for permanent employment. It is expected that the men will be trained to be machinists rather than skilled mechanics. This will simplify training, and make the man more or less self-supporting at an early period. Trade-union rates of wages will be paid, and their pension will sufficiently supplement the wages of those unable to work full time. The workshops are to have ample air-space, but Dr. Tinker does not recommend open-sided sheds. On each site there will be a workshop for 30 to 50 men, with a recreation room, dining room, kitchen and managers' office, instructors', implement, and store rooms, lavatory and washing accommodation. It is expected that the output of work will pay the wages of the men, but of course the workshops will be run at a loss, estimated at 30s. a head, and the Government has been asked for a grant to cover this deficiency. We shall look forward with interest to see the Wimbledon scheme actually at work. It is certainly much more practicable than a new industrial settlement, which in any case cannot materialise for some years. If borough council and care committee coöperate on the lines of Dr. Tinker's paper we should expect very great results, and in any case the mere adjustment of the work done to the capacity of the consumptive which the scheme should primarily ensure will probably very greatly increase the men's prospect of maintaining the improvement commenced at the sanatorium.

ANTIMALARIAL MEASURES AT TARANTO.

TARANTO, in the hollow of the instep of the Italian boot, has a wonderful harbour; a large deep-water bay, entered by a canal; perfectly secure against submarines. It is also the nearest harbour attainable from England by land on the way to Salonika, Egypt, and the East. It was therefore established in 1917 as a great forwarding port with a large rest camp. The southern part of Italy is very malarious, and Taranto is no exception. Antimalarial measures were taken at once, but those taken proved insufficient, and Colonel J. C. Robertson, C.M.G., C.I.E., I.M.S., Sanitary Commissioner with the Government of India, was sent there to plan and carry out what further measures were needed. Of his campaign he gives account in the *Journal of the Royal Army Medical Corps* for May. He was fortunate enough to travel out with Sir Ronald Ross, and in December, 1917, they planned together the necessary works. Naturally the scheme devised by these experienced officers stood the test of practice. The camp was on a hill at the edge of the sea, with higher ground at the back of it and two marshes lying on its flanks. Colonel Robertson discusses antimalarial methods at considerable length and very helpfully, and his reports will well repay perusal. Here it must suffice to say that, commencing as he did in the winter, he first decided to destroy as many mosquitoes as he could at once while they were hibernating. They had to be searched for in houses, huts, and sheds, a toilsome procedure, which, however, gave a census of mosquitoes, and besides trained the staff to recognise and catch them. The mosquito breeding-grounds were next attacked, first those within the camp and then those in successive circles round it. In the camp area wells, tanks, and cisterns were sealed or drained, all hollows in tree trunks were plastered up, and no breeding-ground then remained within the camp. Next he attacked the inner circle zone around the camp. The wells here were sealed, and pumps installed in lieu, the trees were treated as within the camp, the surface drains were cleared and regraded, all springs were underdrained and their water carried to outfalls in which automatic oil drippers were placed. There remained the more extensive, more remote, outer circle zone. The marshes over a mile from the camp were treated similarly but less completely, the nearer marshes were treated as the inner

circle had been. All drains were constantly watched and kept clear of the vegetation which grew up very quickly, wet spots were oiled by hand, and the poor female mosquitoes had nowhere to lay their eggs. The results were eminently satisfactory. Before he began, in the latter half of October, 1917, 32 anophelines were found in the daily search of 11 tents in the camp. In the same weeks of the following year, in the whole of the camp and in three adjacent houses, only 8 were found, while from April 22nd to June 3rd not one anopheline was caught in any hut or tent within the camp. The huts in the camp were also made mosquito-proof with wire gauze, and the effect of all this on the health of the troops was striking, whereas in 1917 among 1500 men there had been 220 malarial cases with 28 invalidings and 6 deaths, in the last eight months of 1918 among 2400 British troops there were only 55 new cases, of which but one was infected in Taranto camp, and among 3000 British West Indians not one primary infection was recorded. On the 1917 liability there would have been, among the 3000, 440 cases, 56 invalidings, and 12 deaths, and among the 2400, 370 cases, 50 invalidings, and 10 deaths. So Colonel Robertson's foresight and judgment may be credited with a saving of 800 cases, 100 invalidings, and 20 deaths, and the debt the troops at Taranto owe to the R.A.M.C. will not even by these figures be fully declared, for they take no account of the large numbers of troops who were always passing through the camp in safety. The paper is illustrated with valuable charts, and its detailed discussion of the principles and practice of malarial prevention make it not only informing but interesting, and a valuable record of a worthy feat of preventive medicine.

ALBEE'S OPERATION FOR CARIES OF THE SPINE.

THE advantages of the free exchange of experiences and ideas between British and American medical men during the war are well illustrated in a paper on the Modern Treatment of Tuberculosis of the Spine by Mr. A. Rendle Short.¹ In conversations with American surgeons Mr. Short was greatly impressed by the glowing terms in which they spoke of Albee's operation for tuberculous caries of the spine. It was described to him as "one of the most gratifying operations in surgery." This seems to be his opinion, too, and he has already performed the operation in four cases, with striking success three times and comparative success once. Yet two of his four patients had been treated unsuccessfully for years by other methods. Albee has used the method since 1912 and described it for the first time in Europe at the International Conference of Surgery at Berlin in 1914. It had already been practised for some years in America at the Mayo Clinic. The operation consists of taking a graft of bone from the tibia, splitting the spines of the vertebrae at the level of the angular curvature, and inserting the graft in the cleft thus made. The spines are split not quite in the middle line, and in addition to the most prominent spine at the apex of the curvature, the four adjoining spines, two above and two below, are also split. When the graft has become welded by firm, bony union to the two vertebral spines above and below the apex of the angular deformity, the five spines form one rigid mass which acts efficiently as a splint. Various modifications of technique have been introduced in recent years, the most important being the use of a semi-circular skin flap to avoid the coincidence of the cutaneous scar with the grafted bone. The operation is subject to the danger, common to all surgical intervention in tuberculous lesions, of spreading the disease. There is also the possibility that the graft may not "take" owing to faulty technique or secondary infection. Dr. Delchef, of Brussels, discusses the operation in *Le Scalpel* of May 1st, 1920, where he states that in 1918 he felt justified by the good results obtained both in Europe and in America to operate on a child of 6, whom he had been treating for two years for Pott's disease in the lower thoracic region. The operation was successful in

¹ Bristol Medico-Chirurgical Journal, March, 1920.

curing the disease, but X ray plates showed a gradual absorption of the graft in spite of extensive contact with spinal bone and without any infection. Such aseptic resorption of the inserted bone is not inconsistent with surgical experience in other parts of the body, but provided that the splint remains in position long enough for the lesion to become healed the method may yet prove of considerable value in certain cases. Mr. Rendle Short believes that, considering the slight risks of the operation and its many advantages, this should be the routine treatment for all cases of tuberculous disease of the spine, with certain reservations, but he has declined to operate in a case in which there were two tuberculous foci in the spine, in another case because several bones and joints were affected, and in a third because paraplegia was present. He also notes that in children under 12 the vertebral spines are so slender that it is difficult to split them properly. This objection holds good for the cervical region at every age. The advantages claimed for this operation are numerous and great. The period of complete recumbency in bed is reduced from 12 or 18 months to two months; the subsequent period during which an apparatus or jacket must be worn is also considerably shortened. And, most important of all, further increase of the deformity is avoided. This operation seems to be particularly suited for working-class patients, to whom the tediousness of more conservative treatment is exceptionally trying. It is probably too early to estimate the proportion of failures to be expected from the procedure, but it appears that non-union of the graft has seldom, if ever, been observed in the absence of gross suppuration. In skilled hands the operation does not involve much shock or hæmorrhage, and it is evidently one which promises to save many patients from disfigurement.

BABY WEEK.

THE scientific tendency to search for and treat only the ultimate cause of such evils as racial degeneration has led to the tracing of a vicious circle from the C 3 adult backwards through the adolescent, the school-child, the infant and its mother, the pregnant woman, and industrial conditions back once more to the young adult. Such continuous reference back leads no further in reform than it does in committee unless a pause is made at each definite stage reached and progress reported. It is satisfactory when the representatives of one section of the public conscience make a stand at one of the stations of the circle and announce their intention of building up a strong edifice of public opinion at a particular point. Four years ago certain people decided that their energies should henceforth be devoted to the care of infants. Realising that endeavour cannot be kept at equal tension throughout the year they formed the National Baby Week Council, to concentrate on an annual effort "to arouse the public to a sense of the importance of infant life, to promote right ideas and ideals regarding maternity and child welfare, to further those methods of safeguarding infant life already existing for its preservation." The welfare of the baby is the particular care of the National Baby Week Council, whose gala week is now being celebrated throughout the country. The fact that a baby's health at birth depends much on that of its mother, and its subsequent development largely on her instructed care, is not ignored by the Council, neither does it lose sight of the fact that a baby is not an end in itself, the chief function of a perfectly good baby being to reach a sturdy maturity. Conferences are being held at Leeds, Manchester, Brighton, Bradford (July 6th), and Wrexham (July 7th), at which the medical speakers will include Dr. C. W. Saleeby, Dr. Eric Pritchard, Dr. H. W. Pooler, and Dr. J. J. Buchan. The subjects to be discussed are widows' pensions, the home and its substitutes, infant-welfare work, and the decay of parenthood. There will also be propaganda meetings, baby shows, fêtes, and mothercraft exhibitions all over the country. There is perhaps no organisation that appeals more to all sorts of men and women than this one, and the latter especially will

find congenial occupation combined with social service in the promotion of a firm, plump, and cheerful babyhood. We have no doubt whatever as to the success of Baby Week.

THE SIGNIFICANCE OF YELLOW SPINAL FLUID.

ACCORDING to Dr. Charles H. Nammack,¹ of New York, who discusses the various conditions in which a yellow spinal fluid occurs, the complete Froin's syndrome consists in (1) a spinal fluid which coagulates at once or upon standing; (2) a yellow coloration or xanthochromia; (3) a marked increase in cells and albumin. The coloration appears to be due to the presence of blood pigments, especially bilirubin, and the increased coagulability to an increase in fibrin. In Dr. Nammack's nine years' work at the Meningitis Division of the New York Health Department yellow spinal fluid was found in 96 out of 5801 cases, or in about 1·6 per cent. After excluding 36 cases in which the diagnosis was never confirmed definitely or there was a lack of sufficient data, the cases were as follows: Tuberculous meningitis, 40; poliomyelitis, 13; cerebral hæmorrhage, 3; meningeal hæmorrhage, 1; cord tumour, 1; pachymeningitis, 1; cerebro-spinal fever, 1. A complete Froin's syndrome was met with in only 6 instances—viz., 2 of meningeal hæmorrhage, 2 of tuberculous meningitis, and 2 of poliomyelitis—the rarity of the complete syndrome being attributed to the fact that acute or subacute types of disease were almost exclusively seen. The amount of cerebro-spinal fluid withdrawn in these cases varied from 3 c.cm. to 50 c.cm., and the colour ranged from the faintest yellow to the deepest canary. In the majority of cases the albumin and globulin were considerably increased. Dr. Nammack concludes that in acute or subacute conditions the presence of yellow spinal fluid strongly suggests the diagnosis of tuberculous meningitis or poliomyelitis.

THE MacAlister Testimonial Fund closes to-day (Saturday) and the testimonial to Sir John MacAlister will be presented, in the form of a cheque, at the annual meeting of the Royal Society of Medicine on Wednesday, July 7th, at 4.30 P.M.

WE remind our readers of the Eleventh Annual Meeting of the Oxford Ophthalmological Congress, which will take place on July 15th and 16th, in the University Museum, Department of Human Anatomy. A detailed programme of the Congress will be found in our news column.

MANCHESTER, in common with other provincial centres, has difficulty in forming a nucleus for advanced graduate work. The large influx of students augments this difficulty. Some of the local hospitals, however, have held successful courses open to all qualified men with the object especially of bringing recent work in concise form before local practitioners. The course at the Manchester Royal Infirmary, which began in October, 1919, was continued on successive Tuesday afternoons and ended on June 29th. The members of the honorary staff of the hospital have each given one or two lectures on subjects in which they were most interested, and which were most likely to be useful to general practitioners. The attendance has been good and the course has apparently been appreciated. It is proposed to resume the work in October next.

INDEX TO "THE LANCET," VOL. I., 1920.

THE Index and Title-page to Vol. I., 1920, which was completed with the issue of June 26th, will be published in THE LANCET of July 10th.

THE BRITISH MEDICAL ASSOCIATION AT CAMBRIDGE.

ANNUAL REPRESENTATIVE MEETING.

FRIDAY, JUNE 25TH.

THE proceedings of the session commenced on Friday morning, June 25th, punctually at 10 A.M., in the Examination Hall, with the Annual Representative Meeting, presided over by Dr. T. W. GARSTANG, the chairman.

It was settled to take the agenda in the printed order of the motions, save that certain recommendations of the Council, in reference to the salaries of medical officers of health and their assistants, were relegated to Saturday, when those officers would be represented by their society; and that the Report of the Medical Consultative Councils to the Ministry of Health, the subject of several motions by the Council of the British Medical Association, was set down for debate on Monday.

The Annual Report of the Council, with the balance-sheet for 1919 and the financial estimates for 1920, was then received and adopted, after which the meeting unanimously accepted the recommendation of the Council that the annual meeting of the Association for 1921 should be held in Newcastle-on-Tyne, with Professor David Drummond as President. It was also agreed that the annual meeting for 1922 should be held at Glasgow. In analysing the financial position Dr. G. E. HASLIP, the treasurer, mentioned that the Government had made a payment of £5000 towards the expenses incurred by the Association in respect of the Central Medical War Committee, a sum, however, which met very little more than one-third of the actual expenditure.

Increase of Subscription and Office Salaries.

A recommendation of the Council that on and after Jan. 1st, 1921, the annual subscription to the Association shall be £3 3s. for a member resident in any part of the United Kingdom and £2 2s. for members resident elsewhere was then considered. To ascertain the feeling of the members, an amendment was voted upon, substituting £2 12s. 6d. for £3 3s., and after debate was lost, when the meeting adopted, by 116 to 22, the recommendation of the Council. The vote was taken by roll-call in order to ascertain to some extent the local feeling of the dissentients. A debate on the necessity of fixing the salaries of certain new officials in accordance with a definite and rising scale led to highly appreciative remarks by the meeting as to the way in which the work of the Association was being done. The motion was withdrawn.

Organisation: The Transformation of the Association into a Federation of Medical Bodies.

Mr. RUSSELL COOMBE, the chairman of the Organisation Committee, brought forward a recommendation of the Council that the Association should take steps to obtain further powers, without altering its present position as an association of individual members, to become, in addition, a federation of medical bodies. It was pointed out that this proposal had been before the Association for some time, notably in 1914; and has now become topical in regard to the Irish Medical Association, which wishes to be legally independent and yet to work in loyal connexion with the Association.

The following Recommendation of Council was adopted:—

That the Representative Body instruct the Council—

(1) To arrange for there being held at an early date a conference of representatives of the overseas branches, especially the branches in the Dominions, with representatives of the Association at home and with representatives of other bodies, if any, who in the opinion of the Council should be invited to such a conference, with a view to arriving, if possible, at a full agreement as to what should be the lines of the proposed new articles and by-laws.

(2) To report further as soon as practicable to the Representative Body on the subject, with, if possible, such draft alterations of the articles and by-laws as the Council may suggest with a view to taking further powers under the constitution of the Association in the way proposed.

(3) To arrange that the draft new articles and by-laws shall *inter alia*: (a) Define the classes of organisations to be admissible,

whether directly, or by means of nominees, to membership of the Association. Such classes to include any portion of the Association which may incorporate itself separately but also desire admission on the new basis, and to include also medical bodies outside the Association and bodies representative of the allied professions anywhere within the Empire. (b) Assign to the Representative Body the settlement of the general conditions of such membership, including decision as to what shall be the minimum numerical backing, within a body seeking to become such member of the Association, which shall render a request for such membership eligible for consideration. (c) Assign to the Council the duty of submitting to the Representative Body, with a view to such membership, the name of any body proposing, or proposed by the Council, to become such member of the Association. (d) Assign to the Representative Body the decision as to whether any individual body applying shall be admitted as such member of the Association, and if so upon what special conditions, if any, in the individual case.

The Supplement to the British Medical Journal.

A rider to a motion, which had been accepted, adopting the remainder of the Annual Report, under the heading "Organisation," embodied an instruction to the Council to ensure an adequate setting forth of the current work of the Association in the Supplement of the *British Medical Journal* week by week.

A debate ensued in which it was pointed out that the question had been anxiously considered by the Organisation, Propaganda and Journal Committees, and that the implied criticism had already been largely met. The rider was adopted, when it emerged from the speeches that while there was much criticism of the Supplement because it did not contain certain things, there had been very little support of those responsible for the production of the paper in the way of useful contributions.

Professional Secrecy.

On Saturday morning the following motion, brought forward originally on the previous day in slightly different terms, by Dr. Langdon Down, the chairman of the Central Ethical Committee, was adopted, after a protracted debate:—

That having further considered the question of professional secrecy, viewed from the standpoint of the medical profession, and with special regard to venereal diseases, the Representative Body reiterates the opinion that a medical practitioner should not, without his patient's consent, voluntarily disclose information which he has obtained from such patient in the exercise of his professional duties.

A rider to this motion seeking to pledge the meeting to the view that the medical profession "should be placed on the same footing as to professional secrecy as clergy, barristers, and solicitors," was lost.

Secret Remedies.

A recommendation of Council, put forward by the Central Ethical Committee, was adopted to the effect that a registered medical practitioner should not make use of or recommend any remedy of which the principal ingredients are not disclosed. This was preceded by a debate revealing considerable divergence of opinion, it being the opinion of some speakers that there were remedies the composition of which could not be familiar but which were of proved value in illness. The wide use of secret remedies by medical men was put in evidence in a striking and amusing manner by Dr. Cox, the Medical Secretary.

Minimum Salaries for Public Appointments.

An interesting debate on this subject took place on Saturday afternoon, the salaries in question being those of whole-time medical officers and assistant medical officers of health. An invitation had been extended to and accepted by the Society of Medical Officers of Health to send representatives of that society to join in the discussion, and accordingly Professor H. R. Kenwood, Dr. W. J. Howarth, and Dr. G. F. Buchan were present. A very large number of amendments were set down.

Mr. E. B. TURNER, chairman of the Medico-Political Committee, said that a certain scale of salaries had been agreed upon by the Society of Medical Officers of Health for their whole-time members. This scale was the subject of recommendations to the meeting from the Council, and had been arrived at, Mr. Turner said, after anxious attention on all sides, and he urged that if the representatives of the society present could make out their case it would be the duty of the association to support them.

An amendment that the recommendations should be referred back to Council being lost, Dr. G. F. BUCHAN explained and advocated the scale as it affected five classes:—(1) Whole-time medical officers of health; (2) whole-time assistant medical officers of health; (3) whole-time senior medical officers in charge of departments; (4) whole-time medical officers employed in departments; (5) whole-time medical officers in hospitals and sanatoriums. The scale of salaries set down for the first class was as follows:—

Population of administrative area.	Proposed minimum salary.
Up to 50,000 ...	£800, rising to £1000 within a period of not more than 5 years.
50,001 to 100,000 ...	£1000, rising to £1200 within a period of not more than 5 years.
100,001 to 200,000 ...	£1200, rising to £1500 within a period of not more than 5 years.
200,001 to 500,000 ...	£1500, rising to £1800 within a period of not more than 5 years.
Over 500,000 ...	£1800.

With, in addition, bonus according to the Civil Service award in force for the time being.

Dr. Buchan, who spoke with clearness and conviction, pointed out that there were three causes of dissatisfaction among his colleagues: their salaries were too small; their duties and responsibilities had been much increased; and there had been no increase in salaries as the result of rise in expenses, except so far as these were met by the war bonus. He pointed out that the scale of fees proposed, which was the essence of the reforms advocated, was the outcome of joint deliberations between the Society of Medical Officers of Health and the British Medical Association. In answer to questions, he said that there were 1400 medical officers of health in England and Wales, of whom about one-third were whole-time officers. He urged the Association to assist them.

Dr. COX pointed out the extreme difficulty in which the business department of the *British Medical Journal* would be put if the adoption of the scale of salaries proposed were followed, as it must be, by the refusal of advertisements from all Authorities which did not accord with the scale. A letter from the Editor of *The Lancet* was read confirming this view, and saying that in such circumstances every advertisement would have to be returned in the first instance to the Authority to ascertain exactly to which class of officer it applied, and how that officer was affected by the size and population of the administrative area.

Dr. H. B. BRACKENBURY said that the practical question was whether the Society of Medical Officers of Health could fight with success the Authorities and those of their medical colleagues who were not in agreement. He instanced Nottingham, using it as an example only because of its particular size, as a city where the whole-time medical officer of health would, under the scale, receive £2400 per annum. Were they to refuse advertisements offering, say, £2200 and ostracise persons who accepted such a salary? Perfectly suitable candidates would come forward in reply to advertisements elsewhere than in *The Lancet* and the *British Medical Journal*, and the Society of Medical Officers of Health and the British Medical Association would suffer from the rebuff. He advocated heartily the increase of the salaries of the officers concerned, and endorsed a later recommendation of the Council that the following definition be adopted:—

Definition.—An assistant medical officer of health is a medical officer duly appointed as assistant medical officer of health by the local authority to assist the medical officer of health in the general administration of the Health Department, and the carrying out of the various Acts, by-laws, orders, rules, regulations, &c., required to be or usually administered by the medical officer of health; the title assistant medical officer of health to be limited to medical officers carrying out these general duties.

An amendment from Newcastle-on-Tyne affirmed that a substantial addition is needed to all public health salaries, but that it is inadvisable for the Association to commit itself further at present.

MONDAY, JUNE 28TH.

The annual meeting of Representatives continued its sittings on Monday, June 28th, Dr. GARSTANG in the

chair. The earlier part of the day had been reserved for the discussion of the

Report of the Ministry of Health Committee.

The Report of the Council under "Ministry of Health," presented by Dr. BRACKENBURY, having been approved, Mr. E. B. TURNER, the chairman, presented a Special Report of the Ministry of Health Committee dealing with the Interim Reports of the Consultative Councils on Medical and Allied Services. He described the work of his Committee, which had been specially directed to the fact that the Reports to the Ministry of Health were interim and not final. An amendment to the adoption of Mr. Turner's Report, put forward by Dr. C. A. BUTTAR and seconded by Sir JAMES BARR, asked the Representative Body to see that the general principles of Lord Dawson's Report were more defined; the Representatives had not had time to digest the arguments. With regard to the establishment of Primary Centres as an essential there were differences of opinion.

LORD DAWSON having put before the meeting the purposes of the Interim Report in a clear and convincing manner, the Representative Body adopted a motion, proposed by Mr. BISHOP HARMAN and seconded by Dr. F. W. GOODBODY, that the establishment of Primary Health Centres was the pivotal idea of the changes recommended in Lord Dawson's Report. This attitude was further upheld in the following motions, put forward by the Brighton division and adopted:—

That in order to attain the objects of an ideal system of Medical and Allied Services it is necessary that the prevention of the occurrence of disease as well as the provision for its treatment should be based on the Domiciliary Medical Service, and that general practitioners should be actively encouraged in the practice of both.

That it be an instruction to the Council to consider and make recommendations as to the scheme which could be submitted to the Minister of Health as requisite for an ideal part-time General Practitioner Domiciliary Medical Service on which all other Medical and Allied Services could be based.

The Ideal Health Council.

An interesting debate ensued upon what should be the proper constitution of a Local Health Authority, in the course of which Lord Dawson explained fully the constitution of the Consultative Councils, their function, and their possibilities.

The following resolution was then adopted unanimously by the meeting:—

That the Representative Meeting welcomes the establishment of the Medical Consultative Council and regards it as an important step in affording essential, organised means whereby the medical profession should exercise its rightful influence on the health policy of the nation.

Dr. BRACKENBURY then moved two resolutions taken, and to some extent adopted by consent, from the Report of the Ministry of Health Committee. The first affirmed the principle that the composition of the Local Health Authority in each area should provide for adequate representation of the medical profession residing in the area, while the second was as follows:—

That for each area there should be established a Statutory Medical Committee to be directly elected by the medical practitioners resident in the area; that the administrative expenses of such Committee should be a charge on the funds of the Local Health Committee; that the duties of this Committee should be to appoint the representatives of the medical profession on the Local Health Committee and on any other committees containing such representatives, and to advise the Local Health Committee on any medical matters; and that this Medical Committee should have the right, whenever it thought desirable, to present its views not only to the Local Health Committee, but also to the Ministry of Health and the public.

The resolutions were approved.

At this point also a unanimous resolution was passed against the principle of a Whole-time State Service.

Resolutions were also passed affirming that postage on the notification of infectious disease should be prepaid by the responsible authorities, and that the fees for post-mortem examinations should be raised by 50 per cent. A resolution was also passed that the fees for police calls should be: day calls 7s. 6d., night calls 10s. 6d. And it was suggested that, as to-day the eight hours day was recognised widely while medical men were on duty all round the clock, for the purposes of adjusting higher night fees, night should be considered to run from 6 P.M. till 9 A.M. the following day.

Report of the Medico-Political Committee.

On a general motion for the adoption of this Report two interesting resolutions were passed among others. It was agreed that the fees for medical witnesses should be raised to 3 and 2 guineas respectively, and that the Council should press for the raising of the fee for the notification of infectious diseases to 5s.

A debate arose under a motion for the restraint of unqualified practice worded as follows:—

That in the opinion of the Representative Body serious steps should be taken in the public interest by the Association to bring to the notice of Parliament the injurious effects of unqualified practice in medicine and surgery.

In reply to the suggestion that the actions of the British Medical Association in this direction had been ineffective, because the evil had so much increased during and since the war, Mr. TURNER told the meeting that at any rate the Government was now alive to the situation, and that sooner or later legislative remedy might be expected.

Fees for Practitioners Summoned by Midwives.

On a motion that the fees for practitioners summoned by midwives should be amended, Dr. BRACKENBURY said that the difficulty was that while the £2 2s. suggested by the Ministry of Health appeared satisfactory in some parts of the kingdom, notably in Scotland, practitioners in many parts of England found the sum insufficient. The following resolution was adopted:—

That the fee of £2 2s. suggested in Para. 1 of the Ministry of Health's proposed amended scale of fees for medical practitioners called in on the advice of midwives is too small to enable the Association to urge practitioners to respond to these calls in areas or cases where they are unwilling to do so.

Motions attempting to allot the payment of the fee between patients and the Authority, and to define the period more justly over which illnesses arising out of pregnancy were treated under the responsibility of the Authority, were lost.

TUESDAY, JUNE 29TH.

The proceedings on Tuesday began punctually, Dr. GARSTANG presiding, with a discussion upon the situation of the medical practitioner in respect of

The Vaccination of Insured Persons.

The debate arose out of a resolution, sent up from the Glasgow Southern Division, protesting against the action of the Scottish Board of Health in saddling the profession with the free vaccination of insured persons.

A resolution was passed instructing the Council to obtain legal advice as to whether this service comes within the scope of the agreement with Insurance Committees.

The Limitation of Panel Lists in Glasgow.

A resolution was passed reflecting severely upon the action of the Glasgow Burgh Insurance Committee in attempting to limit panel lists to 1500, in breach of the agreement entered into between the Government and the Insurance Acts Committee.

Public Health and Poor-law.

Dr. Garstang vacated the chair to move the approval of the Representative Body of the Annual Report of Council under "Public Health and Poor-law," and briefly recounted the long and practical help rendered by the Association to the Public Health Medical Service. He called attention also to the vigorous help extended to this work, in their different capacities, by Sir Philip Magnus and Dr. Herbert Jones. The Report was approved unanimously.

The Payment of Voluntary Hospital Staffs.

Dr. BOLAM, Chairman of the Hospitals Committee, submitted the following motion on behalf of the Council, and it was unanimously adopted:—

That for all work for soldiers and sailors, whether discharged or not, for any disease or injuries connected with the war, undertaken at voluntary hospitals, the medical staffs should be adequately remunerated. For the present the remuneration should represent an addition of not less than 25 per cent. to the cost of maintenance of in-patients, and not less than 25 per cent. of the ascertained cost per patient per attendance for out-patients, the additional sum to be placed at the disposal of the medical staff; that in the case of special clinics—e.g., aural and

ophthalmic—the fee payable to the medical practitioner should not be less than the fee payable by the Ministry of Pensions for identical or similar services—viz., £2 2s. per session.

Paying Patients at Poor-law Hospitals.

A resolution was adopted, asking the Council to arrange for an inquiry and report upon the work of Poor-law hospitals in relation to medical practice outside. During a brief debate it was brought out that there were paying patients who found their way into these institutions, many of which at the present are far from full, and who came accordingly under the care of the medical superintendents, the private practitioners having no access to them.

Paying for Maintenance by Hospital Patients.

The Representative Body adopted a motion—

That the Representative Body is of opinion that the suggested remedy for existing financial straits of hospitals—namely, to demand contributions in aid of their maintenance from the patients, fundamentally alters the basis of the relationship hitherto existing between the honorary medical staffs and the subscribers; and refers the question to the Council for consideration and report.

The Work of the Naval and Military Committee.

Lieutenant-Colonel R. H. ELLIOT, I.M.S., the chairman of the committee, submitted the following as representatives of the Services on the Council for the period 1920-23, and they were duly nominated: Surgeon-Captain Meaden (Royal Navy); Colonel T. D. Barry (Royal Air Force); Lieutenant-General Sir W. Babbie (R.A.M.C.); and Colonel Sir W. J. Buchanan (I.M.S.).

Colonel Elliot then described the work which had been done by the British Medical Association over a long period of years, largely through the assistance of Sir Havelock Charles and Mr. Montague, the Secretary of State, in behalf of the Indian Medical Service. This work, he said, had resulted in raising the Service into a good career.

Sir HAVELOCK CHARLES testified to the work done by the Association in behalf of the medical officers of the Services, and he added that to-day in India a great future awaits the young officer of the I.M.S., but the recruit to that Service must be physically strong and devoted to the work.

Colonel NEEDHAM, Deputy Director-General, I.M.S., said that the British Medical Association's action, while working for reform, had led to a shortage of officers in the Service, and that the logical sequence, now that acceptable terms had been obtained, would be for the Association to recruit for the Service.

A resolution was carried unanimously recording the satisfaction of the Representative Body with the terms now offered to the officers of the I.M.S. Votes of thanks were also passed to the Secretary of State and Sir Havelock Charles.

General Approvals.

The meeting closed with votes of general approval of the annual report and supplementary report of the Council and the election of the new officers and committees.

THE ANNUAL GENERAL MEETING.

The annual general meeting was held, in respect of its first stage, at the Examination Halls, on Tuesday afternoon, Sir CLIFFORD ALLBUTT presiding.

On the evening of the same day the Presidential Address to the Association was delivered in the Senate House, while the honorary degree of LL.D. of the University was conferred upon the following gentlemen:—Sir Clifford Allbutt, Regius Professor of Physic in the University and President of the British Medical Association; M. Jules Bordet, President of the Faculty of Medicine and Director of the Pasteur Institute at Brussels; Dr. Simon Flexner, Director of the Rockefeller Laboratories; Dr. Piero Giacosa, Professor of Experimental Pharmacology at the University of Turin; Sir George Makins, President of the Royal College of Surgeons of England; and Sir Norman Moore, President of the Royal College of Physicians of London.

The ceremony was followed by a reception in King's College, when Sir Clifford Allbutt was presented with the beautiful portrait subscribed for by the members of the Association and painted by Sir William Orpen.

THE MEETING OF THE COUNCIL: RESIGNATION OF DR. MACDONALD.

At the first meeting of the Council for 1920-1921, Dr. J. A. MACDONALD expressed his intention not to present himself for re-election to the office of chairman, an announcement that was received with great regret by this body. Dr. R. A. Bolam, of Newcastle-on-Tyne, was elected in his place. Sir JENNER VERRALL moved, and Dr. T. W. GARSTANG seconded, a cordial vote of thanks to Dr. Macdonald for his eminent services, and speakers representing the medical profession generally in England and Wales, Scotland, Ireland, and the Overseas Dominions, as well as past holders of office in the Association, supported the vote in unqualified terms.

Dr. Macdonald, in a brief reply, explained his resignation as arising out of his feeling that new men should be constantly called upon to serve in these administrative positions in the Association. He thanked his colleagues on the Council for their loyalty to him during his office, pointing out that it was the chairman's duty in the intervals between the meetings of Council to act upon his own initiative, when he had ever striven to make the decisions in accordance with what he believed would have been the sense of the Council in conclave. He concluded by referring to the pleasure that he anticipated deriving from his mission to South Africa in behalf of the Association work.

THE EXHIBITION.

Sir CLIFFORD ALLBUTT opened the exhibition of surgical instruments, drugs, and foods on Tuesday, June 29th. The organising committee are to be congratulated on securing such an admirable building as the Corn Exchange for the purpose. An artistic building, and lofty, with excellent lighting in the shape of an oval glass roof, gave the exhibitors an opportunity of displaying to the best advantage their exhibits. The show was well staged, the tout ensemble was good, and the materials, generally speaking, were of real scientific interest. We doubt if this section of the meeting has come into greater prominence before or attracted more attention.

MEDICINE AND THE LAW.

Does Parental Refusal of Operation Constitute Neglect?

At the Greenwich police court recently a defendant of foreign origin was summoned for neglecting his daughter, a "young person" 15 years of age, by refusing to allow an operation for adenoids to be performed upon her. At the first hearing it appeared that the father and mother were unwilling to have pain inflicted upon their offspring, that they had been told that the case was not serious, that they regarded the administration of an anæsthetic with apprehension, and were generally anxious, no doubt in good faith, to make all the excuses, and raise all the objections usually heard on such occasions. The magistrate was tactful but firm. After hearing all the evidence and explaining the law to the father, including the nature of the penalties involved, he told him that his attitude was obstinate, stupid, and cruel, and gave him a fortnight to think the matter over. When the adjourned case came up for hearing good advice had had its result. The parents had considered the possibility of the father having to undergo imprisonment if he remained obdurate, and had consented to have the operation performed. It had been performed successfully, so the matter ended happily in the taking of the usual recognisances.

The "calling in a doctor" has no doubt long been realised to be the duty of parents when their children are "ill." This duty has, however, at times been distinguished in their minds from that of having a "surgical operation" performed, and "an operation under an anæsthetic" has seemed to them an alarming step, very different from the administration of drugs. In this attitude they have had a measure of public support. For example, we observe that in commenting upon the case above referred to the *Evening News* said:

"Thousands of parents with ailing children will realise with surprise and not a little apprehension that they are liable to imprisonment if they ignore a doctor's advice to have an operation performed." This may indicate the mental attitude of persons who are uninformed upon many other subjects besides their duties as parents; but the law, ignorance of which does not excuse the transgressor, is clear on the subject and in its origin at any rate, older than most of the parents whom it affects. That is to say, the provision of medical aid for children under 14 years of age was first imposed as a duty on their parents by the Poor-law Amendment Act, 1868. No direct reference to medical aid in connexion with the neglect of children was made in the later Prevention of Cruelty to Children Act of 1894 or in an intermediate Act which might have been expected to provide for it. But in 1899, in the case of *R. v. Senior*, in which the Peculiar People were concerned, Lord Russell of Killowen carefully went into the question of this omission, and held that it could not be thought that the legislature intended a step so retrograde as to deny medical attendance to children who had before been entitled to it. He defined the medical aid under discussion as belonging to the class of essential things that reasonably careful parents would provide, and referred to the possibility of occasions arising when the intervention of a surgeon would be included in the treatment necessary. The statute now in force, the Children Act, 1908, includes young persons—i.e., children between 14 and 16 years of age—and, by Section 12, makes it an offence punishable by fine or imprisonment, if a parent (or other person defined as responsible) wilfully neglects in a manner likely to cause a child or young person unnecessary suffering or injury to his health, "including injury to, or loss of, sight or hearing or limb or organ of the body and any mental derangement." The same section adds that a parent or other person liable to maintain a child or young person shall be deemed to have neglected him if he fails to provide "adequate food, clothing, medical aid, or lodging," and further declares that those who cannot themselves procure what is necessary must have recourse to the Poor-law. It will be observed that no obligation is laid upon the medical witness to state with certainty the result of taking or refusing to take any steps recommended, the essential point for the court to consider being whether the alleged neglect is "likely" to cause unnecessary suffering or injury to health. The words quoted which specify injury to sight or hearing, or limb, or organ of the body would be meaningless in connexion with the duty of obtaining medical aid, if "medical" were to be interpreted as excluding all surgical intervention. Attention was called to the bearing of this passage in the section by Mr. Justice Darling in his judgment in *Oakey v. Jackson*, 1914, 1 K.B., p. 216. In that case there was an appeal on the ground that magistrates had wrongly refused to convict, and the operation which the defendant had refused to have performed on his child was for adenoids, so that the Greenwich magistrate had direct authority to guide him. In *Oakey v. Jackson* the magistrates found the facts against the defendant—that is to say, they found that adenoids were causing mental dullness, imperfect breathing, and deafness; that the child was suffering injury to health; and that removal of the adenoids was the only possible remedy. Nevertheless, they had acquitted the defendant, apparently thinking that they had no right to seek to enforce the performance of an "operation," and the Divisional Court ruling otherwise sent the case back to the magistrates for their reconsideration.

An important point, however, expressly laid down in *Oakey v. Jackson* must be borne in mind. Medical men concerned in such cases should note that a refusal to allow an operation is not necessarily such a failure to provide adequate medical aid as to amount to wilful neglect causing injury to health. The question in each case is one of fact to be decided upon the evidence given, and the magistrates must take into consideration the nature of the operation and the reasonableness of the parents' refusal to permit it. "Wilful" neglect in the section has also been definitely

held to mean neglect that is wilful and intentional and not arising through accident or inadvertence. It will be seen from the above that the law on the subject of operations to children has existed for some little time, and that it is clear and comprehensive. The publicity given from time to time to cases which arise under it when parents allow their apprehensions or their ignorance to render their conduct "unreasonable" should have made it fairly familiar to all. There is, moreover, in such cases a right to be tried by a jury, but it must be claimed before the charge is gone into by the magistrate.

The Danger of Headache Powders.

At an inquest held recently at Grimsby the medical evidence attributed the death of a woman to the taking of a "headache powder," combined with a full stomach and heavy clothing. The coroner informed the jury that an analysis of similar powders made for the British Medical Association showed that "a powder" would contain approximately 6·3 gr. of acetanilide. Medical evidence as to the effect of the drug was given, assigning 5 gr. as a dose which might produce collapse. A verdict of "Death by misadventure" was returned by the coroner. It is to be regretted that he did not define the "misadventure." A rider might have been useful to the effect that it was a "misadventure" or "misfortune" for such as the deceased woman that the law should allow the unrestricted sale of possibly dangerous drugs to ignorant persons under the guise of "patent" medicines.

Advertisements in the Medical Press.

The efforts of the Worcestershire County Council to secure ten medical men in connexion with its medical service scheme at salaries of £450 per annum have already been noted in our columns.¹ At a recent meeting of the Council the chairman, Mr. Willis Bund, who was himself one of those who expressed anger at the refusal of *The Lancet* and the *British Medical Journal* to publish the Council's advertisements, had to report to the meeting that advertisements of the posts had been duly inserted in accordance with the Council's instructions by the committee in the lay press. The committee had had many replies to these, but he was obliged to add that nearly all were from persons not suitable for the posts, and that out of the "very small" number who were apparently regarded as comparatively suitable only one could be finally selected for possible appointment. There were, Mr. Bund said, a large number of Irishmen and some Scotsmen among the candidates, but they had not had experience in the class of work which the Ministry of Health required, and he very much doubted whether the Ministry would have approved the appointments. Discussion followed. The Council was advised on the one hand to "put its foot down," and that there were "young men walking the hospitals in London who would be only too glad to accept the salary offered." They were also reminded, not unreasonably, that the posts involved no work at night or on Sundays. On the other hand, Dr. H. E. Dixey, who presented the case from the point of view of the medical profession with clearness and force at the first meeting on the subject, brought to the notice of the Council that salaries such as it was refusing to offer were already being paid in other counties, and that the whole medical service of Worcestershire would be stopped if it did not appoint medical officers. Eventually a motion to give the committee power to go beyond £450 per annum as the salary for the posts offered was carried. The £500 per annum now to be offered as a commencing income can hardly be regarded as the equivalent of more than £250 per annum in 1913. It is better than £450 as a salary with which to commence, and that is all that can be said with regard to it. The Worcestershire County Council, and more particularly those who voted for the increase, are to be congratulated upon having discontinued a struggle for economy at the expense of efficiency, which has had as its result the waste of money spent in useless advertisements and of several months of valuable time.

NOTES ON HOUSING.

(FROM AN AMERICAN CORRESPONDENT.)

The Problem in America.

NOTWITHSTANDING the estimate of the United States labour department that at the close of the war there was a deficiency of 1 million houses, the problem in America cannot be considered as serious as it is in England. The rate of construction of new houses diminished steadily from 1909 to 1918, and although it has risen since that date there is certainly leeway to be made up. A considerable part of the present tension is due to the influx of workers from country districts to large towns in search of the high wages which were recently offered by war industries. At present there are many houses unoccupied in certain country districts. Housing reformers are confident that in a few years the need for buildings of any kind will have disappeared. Their attention is, therefore, mainly concentrated upon the task of maintaining a high standard of planning and construction in the houses at present being built. In this they are aided by the standards drawn up by Mr. Lawrence Veiller, secretary of the National Housing Association, on March 7th, 1918, and subsequently adopted with some slight modifications by the Housing Bureau of the Department of Labour. The standards, it is said, are not intended as inflexible requirements, but any plans which fail to conform to them are not likely to be accepted unless supported by very strong reasons. The standards are contained in a pamphlet¹ of 15 pages, which should be procured by all interested in hygienic housing, for every detail of construction, and even of furniture, has received careful attention. The paragraph on ventilation gives a fair idea of the general standard.

"17. Ventilation.—Every room to have at least one window opening directly to the outer air. Two windows in each room generally preferred; one window sufficient in small bedrooms. Each room to have a window area of not less than 12 square feet.

Cross ventilation as direct as possible to be provided through all rooms, through windows, transoms, or doors; communicating door recommended between front and rear bedrooms in row houses.

Every bathroom to have a window of not less than 6 square feet opening directly to the outer air.

Every water-closet compartment to have a window of not less than 4½ square feet opening directly to the outer air. A skylight in the roof, with an equal amount of glass area and provided with adequate ventilators, will be accepted in lieu of such window, but skylights are not desirable."

The Housing Corporation set a good example when in July, 1918, they were entrusted by Congress with \$100,000,000 to be spent on housing. Refusing to construct temporary shelters, the Corporation set to work to build permanent dwellings, and provided not only for ideal planning but also for adequate travelling facilities for the inhabitants. The Corporation has received a good deal of criticism on account of the expense incurred per house—the average cost at Bridgeport, Connecticut, was \$7263, but temporary buildings would have cost \$2000 and would have been of little "salvage value." More important still, the moral value of the Corporation's activities would have been lost.

A Committee of Women Graduates.

It is impossible for the English visitor in America not to be struck by the attention which the more leisured classes devote to various forms of social service, and by the scientific spirit with which they approach the various problems of social need. This characteristic is well illustrated by the formation early in 1917 of a committee on housing by the Association of Collegiate Alumnae, a national organisation with a membership of over 8000 women graduates. The committee reported on April 2nd last, and we learn from an article in the current number of *Housing Betterment*² that in addition to formulating principles of housing reform "to be attained through restrictive and constructive housing legislation and town planning," they have already

¹ Standards recommended for Permanent Industrial Housing Developments, Department of Labour, Washington, 1918.

² *Housing Betterment*, a journal of Housing Advance. The National Housing Association, 105, East Twenty-second-street New York. May, 1920.

established 46 local housing committees for educational propaganda along the lines determined. The same number of this journal announces that the University of Wisconsin is now offering a course in City Planning and Housing. The course will deal with (1) City Planning; (2) the Housing Problem in General; (3) Industrial Housing; (4) Parks and Playgrounds. It is to be conducted by Professor Leonard S. Smith.

Ourselves—as Others See Us.

It is a salutary exercise to read an American's criticism of our own housing problem and of our methods of dealing with it. The opportunity is given by Mr. F. T. Miller in a pamphlet just published.³ Some of the criticisms are undoubtedly deserved, though we doubt if Mr. Miller has quite realised how large is the problem with which this country has to deal. Some of the criticisms, as, for example, that precious time has been lost in "discussion of substitutes for unavailable building materials" appear to us to be unfounded. The two most important, however, are worthy of some consideration. It is said that after subsidising the tenant we have now by the Act of 1919 instituted a policy of subsidising the producer. Mr. Miller holds that it is only by subsidising the owner that a proper impetus will be given to private enterprise. He has apparently overlooked the fact that under the present law any private house of the required specifications built before Dec. 23rd, 1920, will receive the full Government subsidy, and that by this arrangement the owner of the house pays £180 less to the builder than he would otherwise have to pay. We grant that this is only temporary legislation, and it may be that a wider and more permanent scheme is desirable. We see, however, an objection to the use of Mr. Miller's incentive of "unearned increment" to tempt the private owner; for unearned increment is most readily acquired on the margins of large cities.

Philadelphia, Pa., U.S.A., June 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Scottish Hospital and Nursing Services.

THE Scottish National Health Insurance Commissioners' report on the hospital and nursing services in Scotland has just been issued. It states that the lack of accommodation in voluntary hospitals is mainly surgical, but that it also extends to convalescent treatment, epilepsy, neurasthenia, paralysis, chronic diseases of the heart and respiratory organs, and incurable diseases generally. Many of the smaller hospitals are badly equipped with modern appliances. In hospitals controlled by the local authorities more accommodation is needed for cases of tuberculosis, for infectious diseases in certain thickly populated parts, and for mental cases. There is no evidence that the income of voluntary hospitals is diminishing, but it does not grow in amount sufficient to meet the increased calls. There is need for the greatest economy in utilising and extending the present hospital services. For convalescents and chronic cases use might be made of holiday homes, at present open only during the summer months, and possibly also of some of the auxiliary hospitals at present in existence. The Commissioners draw attention to the present casual relationship between the general and special hospitals, and suggest greater coöperation; they also draw attention to the waste entailed by several hospitals in a centre making separate appeals to the public, instead of combining their efforts. The report pays a tribute to the valuable nursing services rendered, but suggests that the time has come for reorganising in order to obtain better conditions for those engaged in the work, and still further to improve its efficiency.

Small-pox Epidemic in Glasgow.

The outbreak of small-pox in Glasgow as yet shows no signs of abating, and fresh cases are still being reported daily. The disease, however, does not appear

to be spreading with any increase of rapidity, as the number of fresh notifications remains about the same—namely, four to six per day. Since its commencement the epidemic has been almost entirely confined to Glasgow, an occasional case only having been seen in other districts. The danger period, however, is just approaching, when the people of Glasgow enjoy their term of holiday. It is customary for them to go in large numbers not only to the West Coast seaside resorts but to many places farther afield, particularly to Fifeshire and to Midlothian. It seems not unreasonable, therefore, to fear that the holiday period may be accompanied by a much greater dissemination of the disease than has hitherto been witnessed.

Edinburgh Royal Infirmary.

The great campaign to raise funds for the maintenance and improvement of the Royal Infirmary has been most energetically carried out during the last few weeks, and the organisation of the appeal certainly reflects great credit upon those undertaking its direction. No effort has been spared to bring it before public notice and to make it a success. The first list of subscriptions, amounting to just over £50,000, bears witness to the many functions which have been promoted in its aid, and to the cosmopolitan nature of those who are endeavouring to render assistance. The remarkable demonstration which took place on May 22nd in Edinburgh and throughout 17 Scottish counties showed the complete unity of all classes in supporting the Royal Infirmary. The Edinburgh demonstration took the form of a grand parade, which commenced from the King's Park at 6 P.M. and traversed all the principal routes of the city. The procession was several miles in length and took about an hour and a half to pass any fixed point. It was certainly one of the largest—if not the largest and most representative—of all demonstrations which have ever been held in Scotland. A gratifying feature was the universal response made by the various trade organisations, friendly societies, and other similar bodies. It was apparent to everyone that an immense amount of trouble had been taken by those participating to ensure the success of the parade. Every trade carried suitable emblems which indicated the particular occupation of the bearers. Many lorries and other conveyances were decorated in comic style and gave rise to much amusement. Prominent among these were representations of patients in bed in typical infirmary garb, X ray apparatus, and various hospital departments and laboratories. The work of the students was much in evidence, and many of their societies, the Officers' Training Corps, and numerous bands also took part. There were a large number of collectors in fancy dress, and the immense crowds of onlookers lining the streets responded in a liberal manner. The unanimity of all classes, and their enthusiasm, provided a remarkable tribute to the high esteem with which the work of the Royal Infirmary is regarded by the public of Scotland. In the course of this month a special appeal has been sent to every householder in Edinburgh, and it is hoped for a liberal response. The sum required in all is a large one—£250,000—and its attainment is essential if the institution is to be kept efficient and up-to-date.

June 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

A National Institute of Hygiene.

THE creation of a Ministère de l'Hygiène et de la Prévoyance Sociale by the present Government has brought with it the establishment in Paris of a vast national Institute of Hygiene, which will coöperate with the administrative side of the Ministry in the technical organisation of research work, the propagation of knowledge, and the appointment of officials. The Academy of Medicine has been consulted on these great projects, which have already occasioned much dissension in its ranks. M. Léon Bernard, professor of hygiene at the Faculté de Paris, has submitted to a committee the text

³ The Housing Situation in England and the United States, by F. T. Miller. F. W. Dodge Company, New York. 1920.

of a scheme which he has formulated, obviously in conjunction with M. Breton, Minister of Hygiene. The institute will have five sections—epidemiology, social hygiene, dietetics, industrial hygiene, and sanitary engineering. Other departments may be foreseen if to this central institute are to be attached other services now spread over different ministries, such as school hygiene, colonial hygiene, and international legislation on hygiene. Each of these sections will have a research department, a teaching department, and probably a corresponding administrative department. The first will comprise the laboratories and all experimental work and statistical inquiries. The teaching will vary in standard according to whether it is addressed to medical students, to graduates who desire to specialise, or to the health staff about to be formed—nurses, health visitors, chemists, sanitary inspectors, and so forth. According to M. Bernard's report, the teaching would be affiliated to the University and would be under his own personal direction as the professor of hygiene of the Faculty. However, M. Delorme, the Inspector-General, has already formulated objections against this centralisation, which he considers unnecessary and costly—the cost of creating new posts and of the staffing of the teaching laboratories would run into some 700,000 francs. He also considers that centres in the districts concerned are more likely to deal understandingly with local problems. Certain conditions of hygiene are found in the north, others in the south, and others in mountainous regions. The needs of naval and colonial hygiene are better appreciated at the ports than in Paris. The provincial faculties have chairs of hygiene which are inspired by local needs and have developed traditions which should not be disturbed. These objections appear sound and will doubtless carry weight, but they do not interfere with the necessity of coördinating all these diverse efforts; this can only be achieved by a national institute attached to the Ministry of Hygiene and situated in the capital. The results of researches and inquiries made by departmental committees must have an official focus if they are to give rise to the formulation of useful general regulations. In a word, while it is desirable that work should be undertaken wherever it can be usefully performed, the practical application of the principles which emerge is only possible under a single authority. It is necessary to decentralise research and to centralise organisation. This is certainly the spirit of the new Ministry of Public Hygiene. Parliament cannot be said to have stinted this Ministry of money, since at a time of rigid economy it has even allocated a sum in excess of the Minister's demands.

A Giant Nursery.

Professor Pinard, now a Deputy for Paris in the new Chamber, has prepared a scheme for the adaptation of the asylum for the insane, called Asile Nationale de Charenton, into a nursery with room for 1500 children with their mothers. The aim is to establish the most modern and the largest school of puericulture in Europe. The inmates are to be removed before July 31st to give place to the infants. M. Breton, Minister of Hygiene, has recently confirmed the news, and has explained his reasons for adopting the scheme. During last year and these last few months thousands of children have died from lack of care. The maternity hospital and all the lying-in and convalescent homes were filled. The sick could not be kept there. Statistics show figures of infant mortality which are really alarming, and the creation near Paris of an institution of modern puericulture has become urgent. The more serious patients can remain at Charenton for two months, and 9000 children a year should thus be saved. This would make it well worth while to have moved 400 of the insane into the country, where the departmental asylums have 1200 vacant beds. The papers say that this giant nursery will receive patients from August, but the alienists are not accepting without protest the suppression of the most important of the institutions of their specialty in the Paris district. Under the leadership of Dr. Antheaume and Dr. Toulouse an effort was made by many Deputies to wreck the enterprise in the Chamber. They made the point

that the Charenton Asylum only accepts paying patients whose relatives have an actual claim upon the administration, and will not allow their friends to be transported away from Paris without their consent. They also object on the score of the expense originally incurred in the adaptation of Charenton Asylum to its purpose, which will be a dead loss; further, they question the advisability of such a vast conglomeration of children.

June 28th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Colpoplasty from the Ileum.

THE problem offered by malformation or complete absence of a vagina in an otherwise healthy female not infrequently presents itself to the surgeon. Professor Waibl demonstrated at a recent meeting of the Gesellschaft der Aerzte of Vienna a case in which he succeeded in obtaining an excellent result in a female, aged 26, by the following method. The patient, a well-developed healthy girl, had no vagina and desired to marry. Professor Waibl first made a channel between rectum and bladder up to the peritoneum. Then an abdominal section was performed; 12 inches of the lower segment of the ileum were separated, short-circuited, and lateral anastomosis performed. The piece of gut was removed, both ends being carefully closed, and was doubled on itself and then pulled down into the pre-formed channel, perforating the peritoneum. Having closed the abdominal wound, the surgeon fixed the apex of the portion of ileum pulled down to the opening of the artificial channel with silk sutures. The lumen was opened with a Paquelin cautery, and the result was an introitus vagina, patulous for one finger. This was dilated with laminaria for several weeks. The vagina was thus at first a double channel, but usually one of the portions gets wider, while the other narrows down so as not to be palpable. At present the canal is wide enough to admit two fingers. The secretion from the artificial canal is insignificant and not irritating to the vulva. Several methods have been devised to produce a functioning vagina, but the use of the colon or rectum is not so satisfactory. Care must, of course, be taken to use only healthy intestine.

Therapeutics and Pathology of so-called Grippe.

At a recent meeting of the Vienna Medical Society a discussion took place on the pathology and treatment of the severe epidemic of encephalitis lately prevalent in the city. Sometimes lethargic and sometimes choreiform in its manifestations, the term "grippe" has been generally used to designate it, leaving open the question of its precise ætiology. Dr. Neuda spoke of the results of his investigations, which suggest that the chief attack of the disease is directed against the peripheral circulatory system. He studied chiefly the convalescent stage, which showed the following prominent symptoms, all pointing to irritation of the vaso-constrictor system: (1) extreme dilatation of the pupils, which are most susceptible to weak cocaine solutions; (2) an "anæmic exanthem" on the wrist, the forearm, and the dorsum of the hands persisting for weeks, similar to the disseminated oedematous spots in the brain seen in cases of encephalitis; (3) extreme anæmic dermatography; and (4) severe salivation. Similar symptoms occur after extensive burning, also caused by irritation of the peripheral system. Dr. Neuda supposes that the constrictor condition manifested in convalescence is due to a dilated paralysed condition of the blood-vessels during the disease. As regards treatment, good results have been obtained by intravenous injections of a 10 per cent. aqueous solution of a combination of chloride of calcium and urea, staphylococcal vaccines, and horse serum, and hot baths have also been useful. Investigations conducted by Dr. Pollak and Dr. Pfeiffer showed that strychnine did not have the desired effect of raising the blood pressure for a protracted period. More effect can be obtained from caffeine or adrenalin, the

latter being less reliable. A combination of camphor with papaverin gave excellent results; the latter remedy acts directly on the coronary vessels and the heart itself, and has a useful sedative effect. Professor Schlesinger advocated the use of a combination of 5 c.cm. of a 1 per cent. solution of chloride of calcium in physiological NaCl solution, with 1 cm. of digipuratum; daily injections were found very useful in the cases of malaria complicated by grippé. Dr. Epstein gave details of a case of grippé affecting a 31-year old doctor, who died about a year after having suffered from the disease. His peripheral vessels, chiefly of the abdomen, showed severe defects of the muscular coats, proliferation of the interstitial tissue of the intima, and atheromatous changes. In the coronary arteries the media was partly calcified, as well as the elastica interna, with the proliferation noticed above. It seems that during the grippé necrosis of the contractile and elastic elements of the peripheral vessels takes place.

Death of Professor Kretz.

A few days ago Professor Kretz, one of the last living pupils of Kundrat, died after a protracted illness. He was born in 1865, and after studying in Vienna, became the professor of pathological anatomy in Prague and later in Würzburg. His investigations were directed to the physiology and pathology of the liver, and dealt also with diphtheria and serotherapeutics. His papers on antibodies and immunity, on disturbances of metabolism and the pancreas, as well as on embolism of the lung, are most instructive and afford a clear insight into the problems of these conditions. Although ill for many years—he had given up public work as teacher and returned to Vienna—he volunteered at the beginning of the war to serve in military hospitals, and was one of the leaders of the sanitation campaign which succeeded in stamping out war-born diseases from the "hinter-land." His death, though not unexpected, came as a severe shock to his numerous friends and pupils.

June 18th.

MEDICAL GOLF CHAMPIONSHIP.

THE Medical Golf Championship for this year was

THE LANCET Challenge Cup, held by Mr. R. R. Cruise, the medical golf champion for the year 1920. Dr. M. J. Bulger was champion in 1914, since when the contest has been in abeyance.

played for on the course of the Northwood Golf Club on June 24th, and was won by Mr. R. R. Cruise, with the score of two up on "bogey," winning at the same time THE LANCET Challenge Cup. Mr. T. H. P. Kolesar was awarded the Henry Morris Challenge Cup and the gold medal of the Medical Golfing Society for the score of five up on "bogey." In Class I., for players with handicaps of seven and under, the first prize was taken by Mr. Kolesar, of eight and

and in Class II., for handicaps over, the first prize was gained by Dr. G. E. Haslip.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Northampton.—In this county borough the groups of children systematically examined have hitherto comprised only the entrants and the leavers, and cases specially brought forward as needing medical care. From the present year onwards the intermediate group of children from 8 to 9 years old will also be systematically examined according to the usual practice. The total number of entrants and leavers so inspected in 1919 amounted to 3059. Amongst these only one case of definite pulmonary tuberculosis was discovered, and only 35 cases of defective nutrition. In 1918 there had been two epidemic "waves" of influenza, and in 1919 a third wave caused 873 cases among the school population, of which 790 were reported in February and March. The condition of Northampton children as regards vaccination is remarkable. In 1918 the percentages vaccinated of the particular ages 4, 5, and 6, were found to be 12·85, 15·06, and 18·87 respectively; in 1919 these percentages were only 9·00, 10·72, and 11·05 respectively. No provision is made for the adequate teaching of dull or backward children, "and they are at present compelled to waste much of their time in school." Neither is any provision made for open-air education. Dr. G. H. Skinner, the school medical inspector, dwells on the importance of this, which has been conclusively proved to be of the greatest and most lasting benefit to the majority of children. There is a sanatorium school for active tuberculosis cases, and with assistance given by the Northampton Crippled Children's Fund most of the children afflicted in this way are able to attend school comfortably, being provided with the necessary appliances. A special report by Mr. F. E. Ward, the organiser of physical training, furnishes interesting details as to the procedure adopted. He emphasises the importance of "a daily lesson of at least 20 minutes actual physical exercise in pure moving air"; he advocates Rugby football for boys and cricket for girls. From a return as to the employment of school children out of school hours, it appears that 613 boys and 203 girls do work of various kinds, chiefly going on errands (477 children), and delivering newspapers (136); 170 children work before school hours; 147 work after school hours; 30 children work before school hours, also during the midday interval and after school hours; 727 children work on Saturday in addition to other days. "It will be obvious from the above that the by-laws regarding the employment of children of school age are more honoured in the breach than in the observance." The Employment of Children Act, 1903, as amended by Section 13 of the Education Act, 1918, came into force on April 1st, 1920. A new set of by-laws will therefore be necessary, and Dr. Skinner "would urge that the employment of children before school hours be not permitted, and that the by-laws be strictly enforced." If the Northampton ratepayers could be brought to understand that a great deal of their money is wasted in the endeavour to teach children, whose capacity for being taught must be materially diminished by fatigue, due to the work they have to do out of school, there would probably be little opposition. The number of necessitous children fed has fallen from 160 in 1917 to 109 in 1919, and the total number of meals supplied from 70,701 to 41,659. The dietary is excellent and varied. Much good work has been done at the school clinic, where 2891 defects were treated (with 2521 cases), mostly the usual skin, eye, and ear affections. There was a considerable increase in scabies, and it is to be hoped that the recommendation that hot baths should be available at the clinic may be carried out. The difficulty in getting children to wear glasses when they have been prescribed is referred to: "Not unnaturally many children dislike wearing spectacles, and the facility with which they are forgotten or mislaid or lost is remarkable." As a routine procedure a letter has been sent to the head teachers of all children who have been provided with glasses, asking their help to ensure that they are regularly used.

Scarborough.—At Scarborough 1875 children were examined in the code groups during 1919 and in addition 325 special cases. An important but disquieting statement is made by Dr. C. J. W. Tatham, the school medical inspector, as to the increasing neglect of vaccination in this town, which has hitherto held a high reputation as a health resort. Among the children of 12 years of age examined the percentage bearing successful marks of vaccination was 53·64 in the boys and 49·31 in the girls. Among those of 8 years the percentages were 31·22 and 29·14, while in the group of entrants only 26·79 per cent. of the boys and 25·46 per cent. of the girls showed successful marks. For children of all ages taken together the successful vaccinations (which in 1910 had been 44·77 per cent. in the boys and 44·42 in the girls) had fallen to 35·41 and 33·46 per cent. respectively. On the other hand, of 267 special entrants of all ages (newcomers to the town) the proportions of successfully vaccinated children were 66·40 and 61·26 per cent. respectively. As Dr. Tatham points out, "the protection against small-pox afforded by vaccination is being increasingly neglected in Scarborough, the younger children showing the smallest percentages of successful vaccination. The marked neglect of vaccination here indicated may prove of grave significance should small-pox become epidemic in this part of England." If the children in question were to pass all their lives in Scarborough they might conceivably not be injuriously affected; but if their avocations call them to other parts of the world where they may, or indeed will, be in danger of infection, the generation that is growing up will certainly not arise and call their parents blessed. Of course, infection might be introduced into Scarborough any day, with consequent epidemic spread among the unprotected child population. The resulting loss of life in the children and of prosperity in the town can be imagined. The state of nutrition of the school children has not been injuriously affected by the war conditions of the past five years; in 1913 the proportion found to be actually badly nourished was 1·06 per cent., while 16·28 per cent. were considered to be subnormal; in 1919 these proportions were 1·01 and 5·54 per cent. respectively. "Salaries and wages have risen, there has been less unemployment, less poverty, and these have resulted in more food and better clothing." A very satisfactory feature is that "the increased amount of money available has to a large extent been spent on the children." The figures for clothing and for footwear are also considerably better than in 1913; 2·83 and 2·03 per cent. unsatisfactory, compared with 6·94 and 6·73 per cent. On the other hand, war conditions entailed the rationing of food, and it appears that in place of such valuable foods as milk, butter, and eggs substitutes have had to be used, with deficiency of vitamine constituents; and that this has led to spread of tuberculosis, influenza, and increased susceptibility to infectious disease. There were 222 cases of diphtheria with 28 deaths, a continuation of the prevalence in 1918; a large number of cases occurred among girls at the Gladstone-road school in November and December; all the girls were swabbed (353), and 55 were found to be bacteriologically positive. The department was closed for a fortnight before the Christmas holidays, and no more cases occurred. No drainage defects were discovered, but a "general dustiness" was complained of. It was arranged that all woodwork, desks, chairs, &c., should be wiped over with damp cloths soaked in cresol solution after the rooms had been swept and cleaned. With regard to the employment of children after school hours, as Scarborough is not an industrial town, there are not very many children affected; in 22 cases detrimental results were reported by head teachers. Although the situation and surroundings of Scarborough do not appear such as to make an open-air school a necessity, in view of some increase in tuberculosis, Dr. Tatham recommends the establishment of such a school for children that are physically defective. Much good work has been done in the dental department, where 1960 children have been examined and 1204 treated. As to the remedying of defects generally, the results have been most satisfactory. Out of the whole number (1486) treatment has been carried out in 92·79 per cent. of the cases.

URBAN VITAL STATISTICS.

(Week ended June 26th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had declined from 13·8 to 10·6 in the six preceding weeks, further fell to 10·1 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 10·3, or 0·3 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 4·5 in Enfield, 5·1 in Swindon, and 5·4 in Eastbourne and in Oxford, to 16·7 in Great Yarmouth, 16·8 in Exeter, and 19·1 in West Hartlepool. The principal epidemic diseases caused 200 deaths, which corresponded to an annual rate of 0·6 per 1000, and comprised 69 from infantile diarrhoea, 50 from measles, 40 from diphtheria, 33 from whooping-cough, 7 from scarlet fever, and 1 from small-pox. Measles caused a death-rate of 1·6 in Swansea, 1·8 in Leicester, and 2·0 in Great Yarmouth, but the rates from the other diseases showed no marked excess in any of the towns. The fatal case of small-pox belonged to East Ham. There were 1668 cases of diphtheria, 1646 of scarlet fever, and 3 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1705, 1654, and 5 respectively at the end of the previous week. The causes of 14 of the 3455 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham and 2 in Middlesbrough.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 13·6, 12·7, and 13·3 in the three preceding weeks, fell to 11·5 per 1000. The 266 deaths in Glasgow corresponded to an annual rate of 12·5 per 1000, and included 15 from infantile diarrhoea, 5 each from small-pox and measles, 3 from whooping-cough, 2 from diphtheria, and 1 each from enteric fever and scarlet fever. The 74 deaths in Edinburgh were equal to a rate of 11·3 per 1000, and included 3 from diphtheria and 1 from whooping-cough.

Irish Towns.—The 116 deaths in Dublin corresponded to an annual rate of 14·6, or 2·5 per 1000 below that recorded in the previous week, and included 4 from whooping-cough, 2 from infantile diarrhoea, and 1 each from enteric fever, measles, and diphtheria. The 109 deaths in Belfast were equal to a rate of 13·8 per 1000, and included 2 from whooping-cough and 1 each from scarlet fever, diphtheria, and infantile diarrhoea.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Cmdr. W. H. Daw placed on retired list at own request.
Temp. Surg. Lieut. A. W. McKorie transferred to permanent list.
Lieut. A. H. J. Stokes placed on retired list at own request.

ROYAL NAVAL VOLUNTEER RESERVE.

J. H. Garner-Howe reinstated in R.N.V.R. as Surg. Lieut. Comdr.
Surg. Cmdr. F. W. Smith placed on retired list.
The King has conferred the Royal Naval Volunteer Reserve Officers' Decoration on Surg. Cmdr. H. Reah.

ROYAL ARMY MEDICAL COLLEGE.

Lieut.-Col. J. C. Kennedy, R.A.M.C. to be a Professor.

ROYAL ARMY MEDICAL CORPS.

Major A. B. Smallman relinquishes the temporary rank of Lieutenant-Colonel.
Temp. Major C. H. G. Ramsbottom relinquishes the acting rank of Lieutenant-Colonel.
Temp. Capt. A. W. Willcox relinquishes the acting rank of Major on ceasing to command troops on a hospital ship.
Temporary Captains relinquishing the acting rank of Major: J. A. C. Roy, H. L. Neil, W. H. Hardy, T. C. Ritchie, R. E. H. Leach, R. MacDonald.
Capt. A. N. R. McNeill to be temp. Major whilst specially employed.
Capt. G. J. Keane retires, receiving a gratuity, and retains the rank of Major.
To be Captains: Capts. (from Special Reserve) J. W. Cannon, D. H. Murray, A. K. Robb.
Capt. H. G. Dresing, late R.A.M.C., to be Captain.
Temporary Captains to be Captains: E. Underhill, W. Millerick, J. V. McNally, J. S. K. Boyd, C. M. Forster, J. H. Sharpe, L. M. Rowlette, D. J. MacDougall, D. Crellin.
Captains, from Special Reserve, to be Lieutenants and [to be temporary Captains: J. R. S. Mackay, W. L. M. Gabriel.
Officers relinquishing their commissions:—Temp. Major O. Challis (retains the rank of Major). Temporary Captains granted the rank of Major: L. Meakin, G. D. McLean, E. L. Mackenzie.
Temporary Captains retaining the rank of Captain: P. G. A. Bott, F. De C. Keogh, D. Craig, J. W. Edington, G. M. Bluet, J. L. D. Lewis, J. F. Nicholson, K. D. C. Macrae, J. R. Mitchell, B. M. Carruthers.
Temp. Capt. J. P. Mitchell (Captain, R.A.M.C., Spec. Res.).

ROYAL AIR FORCE.

Cpts. C. F. Eminson, A. A. Wilkinson, and M. Hocken are transferred to the unemployed list.

Correspondence.

"Audi alteram partem."

THE PELLAGRA OUTBREAK IN EGYPT.

To the Editor of THE LANCET.

SIR,—In a paper appearing in THE LANCET of May 8th under this title Dr. J. I. Enright gives an account of pellagra amongst German prisoners of war in Egypt with observations upon the food factor in the disease. This contribution is of great interest with respect to several clinical points and very important in its bearing on the fundamental question of the aetiological nature of the disease. It is this latter phase alone that I desire briefly to consider. As the results of his study in relation to the causation of the disease he concludes (p. 1003) that a "food deficiency" can hardly be considered as of paramount importance. In his view "a critical analysis of the diets which these German pellagrins ate before capture and during their period of captivity prior to the onset of the eruption is sufficient to explode the food-deficiency theory as a predisposing factor. These diets were ample, both in quantity and quality, for any possible requirements, and were of such varied composition that it is perplexing to understand how they could have been improved." If, as Dr. Enright reports, these German pellagrins actually consumed before capture and during their period of captivity prior to the onset of the eruption diets that were ample both in quantity and quality for any possible requirements, then it must be granted that the "food-deficiency" theory is, indeed, exploded. Evidently the question upon which the validity of this conclusion depends is: "Did these prisoners actually eat the adequate diet that Dr. Enright believes they did?" Let us examine the facts presented by Dr. Enright and see.

First of all it may be well to note that the great majority of the 7000 to 8000 German prisoners, amongst whom a total of 65 cases are said by Dr. Enright to have occurred, were captured either in September or early November, 1918. The monthly incidence of the disease is stated to have been as follows: January, 13 cases; February, 11 cases; March, 12 cases; April, 14 cases; May, 4 cases; June, 2 cases; July, 7 cases. Certain details with respect to 32 of the 65 cases are presented in a table, from which it appears that in 2 of these 32 cases the period of captivity before onset of the rash was 2½ months; in 3 it was 3½ months; in 13 it was 4 to 4½ months, and in 14 it was 5 to 6½ months. No information as to this interval is given with respect to the remaining 33 cases, with the exception of two German East African cases, who are stated to have been in Maadi Camp, Cairo, for 13 months prior to the onset of the rash. In the absence of any statement of any shorter period it would seem fair to assume that the shortest period of captivity before the onset of the rash was that given in his table—namely, 2½ months. This is important, and should be kept in mind in relation to the points next to be considered.

On the theory of "dietary deficiency" there must, of course, be some period of deprivation before the clinical onset of the disease. As to the duration of this period the available knowledge is unfortunately very meagre. In the experimental cases in Mississippi convicts' mild subjective symptoms were definitely recognisable before the end of the second month, but the rash did not begin to appear until the close of the fifth month. This experience, however, is probably not altogether typical, for certain more recent observations by the writer, made in association with W. F. Tanner (unpublished), make it highly probable, if not certain, that this period may be as short as three months. Under these circumstances it becomes evident that the diet to be studied in relation to the cases of pellagra amongst the German prisoners is that which they ate after, not that before capture. When we attempt to do this we find that Dr. Enright gives us no account of the diet actually

eaten by the pellagrins during the period subsequent to their capture and prior to the onset of the pellagrous rash. He does, indeed, give an account of the diet of the pellagrins before capture, but the "diet after capture" is simply that with which the prisoners in camp and hospital were presumably furnished, not what those who developed pellagra had consumed. Dr. Enright evidently assumes that the pellagrins ate the diet as furnished. In connexion with a point of such crucial importance, however, this assumption is not permissible, as general experience with the vagaries of racial and individual taste in relation to foods, methods of preparation, seasoning, &c., and the literature of scurvy and beri-beri impressively teach. Interestingly enough, however, Dr. Enright himself, quite unconsciously, presents evidence that strikingly illustrates the danger of fallacy involved in the assumption under consideration. He states (p. 999) that "two [of the patients] had had symptoms of scurvy before the rash [of pellagra] appeared." Now, if Dr. Enright's assumption is allowed in relation to pellagra, it must, of course, be allowed in relation to scurvy; it would thus follow that a "food deficiency" can no more explain the origin of scurvy than it can, according to Dr. Enright, explain the origin of pellagra in these men, and consequently the "food-deficiency" theory of scurvy must be considered as "exploded" equally with that of pellagra. Far from being "exploded," however, the food-deficiency theory of scurvy was never more solidly established than at present. It follows, therefore, that the diets allowed the German prisoners were (1) not "ample both in quantity and quality for any possible requirements"; or (2) not distributed as prescribed; or (3) not eaten as furnished them.

Since the number of cases of scurvy and of those of pellagra were relatively very few, it is fairly certain that the diet allowed was adequate so that such faults as developed were probably the result either of improper distribution or of individual eccentricities of taste or, perhaps, of both. In this connexion it may be recalled that prior to capture these German prisoners are said to have lived on "the fat of the land," so that it seems not at all improbable that at least some of them did not find the prison camp diet furnished them after capture physiologically adequate, though it may have been altogether to their liking, leading such either to reduce their normal total intake or to reject certain, to them, objectionable (because of character, flavour, seasoning, mode of preparation, &c.) articles. That a "food deficiency," leading to such condition or conditions as scurvy, war oedema, beri-beri, or pellagra, should thus arise is no more than might be expected, particularly in such as might at the same time be suffering from a depressing illness or mental aberration.

From the foregoing considerations it is evident that Dr. Enright's conclusion that the food-deficiency theory of pellagra is exploded is not well founded, and it follows, further, that the "toxin hypothesis" which Dr. A. D. Bigland² felt it necessary to advance in explanation, seemingly, of Dr. Enright's cases, would appear to be superfluous. In this connexion brief reference may perhaps be made to Dr. Viswalingam's paper³ mentioned in the editorial on "Pellagra and Diet" in THE LANCET of May 8th (p. 1019). It appears that from his observations Viswalingam was "led to conclude that faulty diet in itself cannot cause 'pellagra,' and that there is a superadded infection." For, he argues, "if diet should be the sole factor, then the affected individual should improve, and there should be no recurrence when he is removed to a hospital and placed on a liberal diet, &c." "But," he goes on, "this is not so, as shown by cases that were kept in hospital for considerable periods and in which the disease, far from showing any improvement, advanced and the cutaneous lesions and gastro-intestinal disturbances were seen to recur at each succeeding season." One might accept this reasoning as perhaps conclusive if (1) the "liberal diet" is a biologically complete and adequate one, and, more important still, if (2) being "placed on" such a diet and actually

¹ Goldberger and Wheeler: U.S. Public Health Reports, Nov. 12th, 1915, and U.S. Hygienic Laboratory Bull., No. 120, February, 1920.

² THE LANCET, May 1st, 1920, p. 953.

³ Journ. Trop. Med. and Hyg., Feb. 19th, 1920, p. 46.

consuming it could be assumed to be synonymous. That this assumption can be allowed only as a broad general proposition and that it may fail in individual instances has already been sufficiently indicated in connexion with the essentially identical assumption by Dr. Enright. In the light of the results of large-scale experiments designed to test the preventability of pellagra by means of an appropriate diet,⁴ I may, perhaps, be permitted the suggestion that Dr. Viswalingam's unsatisfactory results may be accounted for on the ground either that this "liberal" diet was not really an adequate one, or, more probably, that the patients did not eat it. They may not have consumed this diet either because it was not given or because the patient refused some parts (poor nursing), or, finally, because he was dealing with complicated cases (evidences of dysentery, ankylostomiasis, malaria, and scurvy were present in at least 60 per cent. of his cases), or cases so far advanced that recovery was impossible. In this connexion it may be pointed out that the value and the significance of the results of the therapeutic test of diet is much inferior or, more properly, must be differently gauged from that of the preventive test. In evaluating the significance of the results of the former allowance must be made (exclusive of complications) for the varying degrees of severity and extent of the existing damage from the disease, so that recovery in the majority of (severe) cases is all that can, perhaps, be reasonably expected; in prevention, however, assuming proper control of the diet and of the pellagrin, practically complete eradication may with confidence be expected.

It follows from the foregoing that Dr. Viswalingam's hypothesis of a "superadded infection," like Dr. Bigland's "toxin hypothesis," has been invoked without substantial grounds, and like the latter must be regarded as superfluous.

I am, Sir, yours faithfully,

JAS. GOLDBERGER,

Surgeon, U.S. Public Health Service.

Washington, June 5th, 1920.

CARRIAGE OF MALARIA BY HIBERNATING MOSQUITOES.

To the Editor of THE LANCET.

SIR,—I have been reading Colonel S. P. James's most interesting book on "Malaria at Home and Abroad," which has just been published, and I should like to correct an error which appears on p. 14. He says that in the Balkans I showed that 40 days were required for the malaria parasite to attain maturity in the mosquito at a temperature of 62° F. I conducted a number of experiments with mosquitoes and malaria, but in none did I find such a long period of development, except in cases where the latter was intentionally arrested by exposing the mosquitoes to hibernating conditions. Large numbers of mosquitoes were dissected from Lehanah village, where there was a high malaria rate amongst the children and where the prevalent mosquito was *Anopheles superpictus*. These dissections were carried on through the summer and winter of 1918-19, and an interesting result was that partially developed oöcysts were found in mosquitoes all through the winter. The oöcysts appeared to be normal, and the question arose as to whether it would be possible for such oöcysts to continue their arrested development when temperature conditions became more favourable.

In the Macedonian village the anopheles pass the winter most usually in the barns or cow-houses below the living-rooms of the natives. In these the temperature is considerably higher than in the empty barns, where mosquitoes are more rarely found. During the winter the mosquitoes are constantly feeding on the animals. Experiments were instituted, and it was found that in mosquitoes which had been fed on malaria cases and then incubated for a week the development of the oöcyst could be completely stopped by exposure to a temperature corresponding to the winter hibernation temperature of the mosquitoes. After three weeks'

artificial hibernation the oöcysts continued their development when the mosquitoes were again incubated. It is thus quite possible, if not probable, that the oöcysts which I saw in the hibernating mosquitoes collected in the village, and which resembled in every way those seen in the experiment, would be capable of completing their development in the early part of the year when the temperature became sufficiently raised.

The experiments I carried out seem to prove that the malarial parasite can be carried over the winter by the hibernating mosquitoes. Exposure of infected mosquitoes with partially developed oöcysts to a low temperature in the ice-chest for 12 hours did not produce degeneration of the oöcysts, whereas a longer exposure did do so. It would seem that in nature a temporary exposure to a very low temperature on an exceptionally cold night would not prevent the subsequent development. I think it is possible that Colonel James has obtained the figure of 40 days from some of these hibernation experiments. I call attention to the carriage of malaria by hibernating mosquitoes because of its importance in antimalaria work, for it emphasises again the advisability of destroying the hibernating females during the winter. My experiments will be fully described in a paper which will be published later.

I am, Sir, yours faithfully,

Wellcome Bureau of Scientific Research, C. M. WENYON.
Endsleigh-gardens, Gordon-square, N.W., June 23rd, 1920.

VARIOLA, VARICELLA, AND ALASTRIM.

To the Editor of THE LANCET.

SIR,—In the annotation in your issue of May 29th entitled *Anomalous Cases of Small-pox*, a list of characteristics is given which are said to differentiate the disease called "alastrim" from varicella on the one hand and from variola on the other. It is not stated where or when the observations which must underlie these formal distinctions were made, or on what authority the claim that they serve to differentiate alastrim from varicella and variola is based. To enter upon a detailed criticism of each feature in the list would take up too much space, but considering the supreme importance of the accurate differentiation of the small-pox rash from other rashes of similar type, it seems to me to be remarkable that the value in differentiation of observations of the distribution of the rash is not even suggested. Is it to be assumed from this omission that the distribution of the rash in alastrim cannot be distinguished from the distribution of the rash in varicella or in variola? Or is this factor in diagnosis considered to be of minor importance in comparison with those given in the list? In either case it is desirable that the omission should be rectified and that any observer who has had the advantage of opportunities of comparing alastrim with varicella on the one hand and with variola on the other should set down the results, whether positive or negative, of his observations. Dr. S. Monckton Copeman in the last sentence of his letter in your issue of June 5th says: "In both outbreaks the symptoms and general course of the disease more nearly resembled those of alastrim than of typical small-pox," but he makes no reference to the existence of a distribution sign as a factor in diagnosis, and although I had the advantage of hearing the interesting paper which he read before the Epidemiological Section of the Royal Society of Medicine, I failed to appreciate that he had observed any differences in the features of the distribution between the cases which he cited and the cases of true variola which were associated with his cases in the Norfolk and Suffolk epidemic.

If I seem to lay undue emphasis upon this factor in diagnosis my excuse is that in the London Receiving Station and in this hospital, following the teaching of my predecessor, the late Dr. T. F. Ricketts, we have always regarded the features of distribution as of paramount and really overwhelming importance in the examination of suspected rashes of focal type. It may therefore be understood that a list of tests in which this factor finds no place must fail to inspire confidence in anyone who has appreciated Ricketts's teaching or has personal know-

⁴ Goldberger, Waring, and Willett: U.S. Public Health Reports, 1915, vol. xxx., p. 3117, and unpublished data.

ledge of the results which are obtained by the use of his method of differentiating the focal rash of small-pox from other rashes of similar type. In fact, if the claim that the conditions as set out in the list serve to differentiate alastrim from variola and from varicella is sound, there is no doubt that among the 11,000 patients admitted to the London Small-pox Hospital during the last 20 years there were many cases of alastrim and of varicella indiscriminately mingled with the cases of true variola. Under such conditions it is remarkable that during this period second attacks or relapse of disease or the intercurrent appearance of a focal rash (accidents of this nature might appear under any of these headings in the hospital records) have never been recorded. Vaccination has been used and is now used in a small proportion of difficult cases as a crucial test in diagnosis, but since only a very small proportion of the cases sent into hospital were subjected to vaccination for this purpose at the receiving station, and since it is claimed that vaccination confers an immunity of only limited duration to alastrim, the complete absence of secondary rashes of the focal type seems to require explanation.

Unfortunately I have had only one opportunity of examining a case in which the diagnosis of alastrim was suggested, and in regard to it I can only say that all the important signs of small-pox were present when the case first came under my observation. In my experience the full development of these signs may in some cases of genuine small-pox require five or even six days, counting from the appearance of the first lesions. The outbreak of epidemic small-pox is so frequently accompanied by the appearance of diseases similar in type of eruption but yet differing in a nondescript sort of way from true variola. It was so in 1902 when Cambridge was attacked. Again, a few years later a discussion was raised concerning "amaas" and its relation to small-pox in South Africa. Now we have alastrim. But no one has offered to explain why these nondescript diseases have been in all these instances associated and not infrequently in series with cases of typical and therefore unmistakable variola. Small-pox is a protean disease. At the present time the practical work of differentiating the focal rash of small-pox from other similar conditions must depend on clinical observation. Until the time arrives when an advance in bacteriological method may enable us to recognise the existence of varying types of the organism, it would seem to be the safe course for us in this country to continue to assume that variola and varicella are distinct diseases which breed true and differ in their clinical characteristics, that vaccinia is a relative of variola, behaves as such, and under certain well-defined conditions is a crucial test for the presence of small-pox. We may thus avoid on the one side the fallacy of the new disease or of the new benign type which is so prone to revert to the original savage, and on the other the absurdity of the suggestion that varicella should be isolated.—I am, Sir, yours faithfully,

A. F. CAMERON,

Medical Superintendent, River Hospitals and Ambulance Service, Metropolitan Asylums Board.
Dartford, Kent, June 26th, 1920.

THE ASSESSMENT OF HAND INJURIES.

To the Editor of THE LANCET.

SIR,—I am much interested in Mr. J. J. Scanlan's article on this subject in your issue of June 26th. Speaking only from a year's experience as chairman of a Pensions Board, I consider his suggestion of a diagram of the pensioner's hand excellent. I am inclined to think that too much time is at present spent in the minute description of scars, frequently to the exclusion of more important facts. It is, however, surprising how easily glaring errors in description may arise during the stress of actual examination. The differentiation of the thumb causes difficulties in the description of the hand to be greater than those of the foot, although dorsiflexion at the ankle provides pitfalls. It is easy in dictating a description of a hand injury to subconsciously associate the first metacarpal with the

first finger, and a momentary loss of concentration of attention, due, perhaps, to an adjacent board's struggles with a deaf pensioner, may even lead to the substitution of the word left for right, with disastrous results to the description.

The subject on which I should have liked a fuller expression of opinion is the proportional disability of the loss of the hand compared with amputations higher up the limb. Speaking again from my limited experience, amputation of a hand or complete loss of use is a very serious disability, and in my opinion a lesser assessment on the usual scale compared with amputations higher up is only justified if the man can be fitted with a useful appliance. A practical detail in the elucidation of the utility of the hand is that every pensioner should undress himself in the examiner's presence. Although when done as a routine it apparently leads to waste of valuable time, it is really of great importance, as he will often unconsciously demonstrate the presence of more usefulness in the hand than is apparent at the subsequent formal examination.

I have been disappointed hitherto with the types of artificial arms I have come across. It is true that some are marvels of ingenuity; the pensioner newly provided with such an arm will give himself a twist, the mechanism clicks, and he shows with evident pride how he can pick up a match from the table. But after a time the tendency seems to be to only wear the arm on State occasions. A much more useful contrivance seems to be that of a forearm piece into which the tools of a man's trade can be individually screwed.

But the point which I think has struck me most as regards disabilities in general in this age of specialisation is that so far as elderly men and adults are concerned it is of supreme importance to try to enable the pensioner to follow his pre-war occupation rather than to advise him to learn a new trade.

I am, Sir, yours faithfully,

FRANCIS HEATHERLEY, M.B., B.S., F.R.C.S.

Ashville, Audenshaw, Manchester, June 27th, 1920.

THE CLINICAL DIAGNOSIS OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I see from your issues of June 5th and 12th that my statements *re* the above have not been allowed to pass unchallenged, nor is it desirable that they should, for the subject requires critical investigation in order, if possible, to arrive at the truth. I am grateful to you and to your correspondents for their criticisms, and will reply to the various points *seriatim*.

(1) In reply to Dr. A. K. Gordon, I do not for one moment suggest that ocular diagnosis should be used "as an alternative" to bacteriological investigation. As a matter of fact, a bacteriological examination has been made in every case of "diphtheria" under my care at the fever hospital. This ought to be done in every case of ulcerative or membranous sore-throat. I maintain, however, that naked-eye diagnosis, *if reliable*, is much more important than the bacteriological, and I have always given my diagnosis from the naked-eye appearance, and have only in a few cases prescribed any antitoxin in "diphtheria" cases that did not show what I considered were the characteristic appearances of the disease; and then only as a possible preventive. (a) I have not been impressed with the difficulty mentioned by Dr. Gordon under this paragraph. How does Dr. Gordon diagnose scarlet fever in the absence of the rash? If the typical rash and sore-throat are present where is the difficulty? (b) How does the naked-eye appearance differ as it affects (1) adults, (2) children? I have failed to observe any difference, and shall be interested to learn what has been observed elsewhere. In not a single case of "diphtheria" where I made the diagnosis of tonsillitis did I succeed in finding the Klebs-Löffler bacilli, even after 24 hours' incubation. Is not the diphtheria germ occasionally found in the throat not only of healthy nurses but also in healthy individuals outside hospital? (c) So far as I am aware, there have been only two cases of scarlet fever sent into hospital as "diphtheria." It is clear, therefore, that in

this area scarlet fever is not "*the disease in which the differential diagnosis is most important*"; at any rate, it is not the one in which mistakes have most frequently occurred; whereas in regard to follicular tonsillitis and influenza mistakes have been common. Neither is it my experience that the co-existence of scarlet fever and diphtheria is "*commonly seen*" as stated under (a). In a few cases of scarlet fever the throat looked "*suspicious*," and I prepared cultures; in each case the result was negative.

(2) "*A Veteran*" asks if my method of diagnosis is not "*too good to be true*." The answer to this is that for over three years it has been true.

(3) I am particularly obliged for the remarks in your leading article on p. 1276, and agree with many of them. You say there, "*but cases are surely not uncommon in which a single patch is present in the tonsil*." In tonsillitis, I think if practitioners will examine *the whole* of the tonsillar area with care they will find the single patch extremely uncommon. With many cases of diphtheria there is some tonsillitis, but this is quite distinct from "*follicular tonsillitis*," and in the latter disease I have never seen a single patch since I began to examine the throat critically, and I have on several occasions seen three or four patches after being informed by other observers that there was only one. I have heard several medical men say they "*think*" they have seen such or such an appearance. May I draw the attention of my medical brethren to the fact that my statements are based on graphic records, made at the bedside of the patient, so that there has been no need to "*think*" whether the patch was single or multiple.

I should like to ask Dr. Gordon to be good enough to state what he considers the characteristic appearance of diphtheria (of the fauces); or if he always has to wait for the report of the bacteriologist. Is the report of the bacteriologist always reliable? I think not. Only a short time ago I sent a specimen to one of the leading professional bacteriologists in the kingdom and was informed that diphtheria bacilli were present; then, a few days later, I received another note stating that the bacilli present were not the true Klebs-Löffler bacilli, though indistinguishable from them as seen under the microscope. It is also well known that a negative result is not infrequently obtained on first examination, and afterwards a positive one in the same patient—i.e., at first the bacteriological diagnosis is *wrong*, and if followed as a guide to treatment would be likely to lead to the disastrous results which Dr. Gordon refers to as likely to arise from depending on the eye alone. I may add that the published drawings illustrative of my paper in THE LANCET are only a small selection of about 200; all the rest, however, illustrate the same points and might equally well have been chosen. In conclusion, allow me to express the hope that this discussion will ultimately lead to a more satisfactory diagnosis of infectious diseases of the fauces. The description that I have given relates to what has been seen at the Wrexham Fever Hospital and in my own private and consulting practice; it is for others to state what is seen elsewhere.

I am, Sir, yours faithfully,

Wrexham, June 19th, 1920.

H. DRINKWATER.

THE EPIDEMIOLOGY OF PHTHISIS.

To the Editor of THE LANCET.

SIR,—In the introduction to Dr. John Brownlee's recent research publication on the Epidemiology of Phthisis, the Medical Research Council say that the division of the disease into types is "*a challenge to the bacteriologist and clinician alike to coöperate in closer analysis of the different infections and of the responses to them made by the body at various ages and in particular environments*." "*These two (or perhaps three) types either correspond with separate types of infecting bacillus, as Dr. Brownlee inclines to believe, or they mark different types of physiological response made by the human body to the infection at different ages*," and I would add to the latter, "*with definite racial or family characteristics*."

I would like to present the case from another aspect, as a clinician, but in no way desire to differ from the most astute and painstaking observations by which Dr. Brownlee has shown us that phthisis must be definitely divided into types.

As a clinician I have unreservedly accepted Dr. Brownlee's young adults (Y.A.) and middle-age (M.A.) types. After reading Dr. Brownlee's first paper I divided into groups 31 deaths from the insured patients whose duration of illness was accurately known and was specially investigated for this purpose. These groups were three: The first, those dying within one year of first symptom; second group, those in whom known symptoms had existed over two years; and third, the intermediate and indeterminate group dying between one and two years from the onset of disease. None of the 14 constituting the first group dying within the year were found to be between the ages of 22 and 43, 7 (or half) were between 17 and 22 years of age, and the remaining 7 were all over the age of 43 and would presumably come in Dr. Brownlee's old-age (O.A.) group. There were 9 cases in the chronic class with symptoms of over two years' duration; 8 of these died between the ages of 22 and 43, and would constitute Dr. Brownlee's middle-age (M.A.) type. The intermediate group of those dying between one and two years after the first onset of symptoms, 9 cases in all, were of all ages from 17 to 55.

Clinically the three types apparently exist, and they coördinate with the duration of the illness. Y.A. and O.A. are acute and M.A. is chronic, and the other deduction seems also correct, that the middle-aged type (M.A.) is subject to environmental conditions and is eminently curable. Y.A. and O.A. types are far more difficult propositions, but in all families believed to be subject to Y.A. type, susceptible persons were given prophylactic doses of tuberculin (P.T.O.), which so far has proved efficient in preventing any subsequent cases developing among them. This accords with Dr. Brownlee's observations that early milk infection protects from Y.A. type. These cases are too few to found any positive deductions on, but are very suggestive that, clinically, coördination exists between the age and the type of the disease, as suggested by Dr. Brownlee's paper.

Coming now to the cause of the type, I started out with the idea it was strainal, or caused by a special variety of tubercle bacillus, but have now come to the opinion it is a physiological age response accentuated by certain family or racial characteristics. The response of the human tissues to the tubercle bacillus is an age response all through, both in its active and in its immune periods, but acts quite differently in men and women. In early years the danger to woman is very great, but in her case it steadily diminishes with her increasing resistance as age progresses till, in Australia at any rate, it is almost non-existent among women between the ages of 45 to 50. In the male the danger to those attacked between 15 and 25 is not so great, but reaches its highest point between 45 and 50. Physiologically men and women are under very different conditions. A woman usually reaches her maximum strain before 30 and then steadily diminishes, but a man's maximum strain is not reached till after 40.

In regard to the proposition advanced, "*How far has the elimination of the susceptible made for the improved urban conditions?*" there are fewer susceptible families, I think, than is generally supposed. In 125,000 people investigated there were only five proved susceptible families, and I think this elimination of susceptibles in towns is due to greater marriage intermixture, raising the resistance to a higher level.

Considering possible causes of the decline of phthisis in recent years, I would add a sixth cause to Dr. Brownlee's five—namely, the increase of resistance resulting from inter marriage, as well as from the improved hygienic conditions that the intermixture of races has promoted. This cause affects the Y.A. type especially. Should this view prove correct, the position would be that Y.A. phthisis, being principally a racial and family disability, would be advantageously affected by movement of population. Whereas M.A. phthisis, being a hygienic and physical strain disease, would be principally affected by hygienic conditions of work and feeding. The industrial migration in Lancashire would thus account for the fall of Y.A. phthisis death-rate, which has occurred without affecting M.A. phthisis.

No consideration of causes of modern variation can be complete without taking into account the alteration in the type of foods used in large towns. The whole-foods of our ancestors, with their complete vitamins, have been largely replaced to-day by the manufactured foods, with their absence of vitamins. The food factor to-day is one of increasing importance, and there seems no doubt that both butter-fats and good fresh meats have certain unknown resistance-raising qualities which are not found in modern margarine and in the tinned and frozen meats so largely used by the working population.

To my mind Dr. Brownlee gives away his own case for strain differentiation as against physiological and racial differentiation in the production of types of tubercle when, in the paragraph discussing the incidence of phthisis in Wales (p. 64), he writes:—

"In the district of Pembroke itself, that is the district South of Milford Haven, there is little phthisis. This absence of tuberculosis occurs in spite of the fact that the cattle of South Pembroke are largely Short Horn, a breed which is very subject to tuberculosis, while the cattle North of the Prescilly Mountains are of the long-horned black Welsh breed, which is seldom affected with that disease."

Surely if the breed in cattle varies the incidence without presupposing a special strain of bacillus the same should hold good in man. But however this may be, and however we may differ as regards the interpretation of the facts, the fact remains that Dr. Brownlee has conclusively shown that in future phthisis must be divided into three types for investigations if we are to attain to any results, and that his description of the types and their associated relations are clinically correct. Clinically the middle-age type (M.A.) is essentially environmental and certainly can be dealt with, given control of that environment. The question is one of individual resistance and is thus an eminently treatable proposition. At present we have not sufficient evidence to show that this is the case with the Y.A. type, which I regard as largely a question of family and race which will tend to die out with racial intermixture. As far as the British races are concerned the racial strains liable to Y.A. tubercle must be mainly those of Celtic origin, with whose temperamental proclivities we must all be acquainted. We must remember that early tubercle is essentially a nervous disease, or rather that a nervous condition manifestly tends to the loss of resistance which is so serious a factor in those thus threatened.

In considering the geological epidemiology, a necessary factor, clinically a cardinal factor, is the occurrence of lime in the drinking-water. I believe there are considerable grounds for stating that other things being equal people bred and resident in lime districts or those whose drinking-water is impregnated with lime are more resistant clinically to tuberculosis, and this is natural, as lime is Nature's method of combating the disease. I have recently had a remarkable confirmation of this view from Dr. E. A. Wilson, of Keighley, who writes:—

"Half my district is on clay, the other on agricultural limestone. Excluding urban areas, I see large numbers on the clay area and very few in the limestone area. In fact, in the limestone area, a branch dispensary had to be closed from lack of patients, and the few patients in that district do far better than in the clay area."

If these remarks promote discussion from the clinical side of the type problem of tuberculosis their object will have been attained. May I say, in conclusion, that every tuberculosis officer should read Dr. Brownlee's Part III., as it will be found an essential starting-point for all future thought on the subject.

CONGENITAL STENOSIS OF THE AORTA.

To the Editor of THE LANCET.

SIR,—We have been interested in Dr. R. O. Moon's case of congenital stenosis of the aorta described in THE LANCET of June 19th. A case resembling it in some respects was recently under our observation, and the variations in the electrocardiograms taken from it make it also worth recording.

The patient was a boy of 10 years, stunted in growth, and complaining of general debility. His mother reported that he showed "blueness of the face when bathing" and that he had not suffered any special illness. His apex beat was in the fifth interspace and was not particularly forcible. A pronounced systolic thrill was palpable over the aortic area. Cardiac dullness was slightly greater than normal at the base and normal at the apex. A systolic murmur was audible at the aortic, pulmonary, and mitral areas, having its point of maximum intensity in the second right intercostal space, and its only direction of conduction upwards towards the carotid. Radial tracing showed pulsus tardus. The physical signs and symptoms strongly suggested congenital stenosis of the aorta.

An electrocardiogram taken on Feb. 10th, 1920, showed the T-wave to be inverted in Leads II. and III., the P-wave was inverted in Lead III., and there was preponderance of

the left ventricle. A second electrocardiogram taken on March 5th showed that the T-wave in Lead II. was no longer inverted, the line between R and P remaining practically straight. A third electrocardiogram was taken on April 9th, and showed the T-wave in Lead II. to be of normal outline. The other features of this electrocardiogram were unaltered and remained as in the first one. The patient was not under the influence of digitalis at the time these electrocardiograms were taken.

If inversion of the T-wave in Lead II. is invariably a sign of degeneration of cardiac muscle and therefore of grave prognostic import, as it is held usually to be, then the return of such T-wave to its normal outline ought not to be expected in the course of a few weeks. In this relation the post-mortem finding of normal heart muscle in Dr. Moon's case is very significant. Is it more than a coincidence that these two cases, which exhibit inverted T-waves in Lead II. are cases of congenital aortic stenosis and may such a cardiographic feature be considered characteristic of this form of congenital heart disease? We have not observed it in any other type of congenital heart disease, but we should like to learn the experiences of others in this respect.

We are, Sir, yours faithfully,

MURRAY BLIGH,

Honorary Physician, Northern Hospital, Liverpool.

I. HARRIS,

Honorary Physician Cardiographic Department,
Northern Hospital, Liverpool.

RACE PATHOLOGY.

To the Editor of THE LANCET.

SIR,—Dr. G. Rome Hall's contribution to race pathology, which appears in your issue of June 5th, is of practical importance. Until recently, when Jewish learned societies took steps to collect statistical facts concerning the Jewish race, most of the references and statistics on comparative racial pathology were obtained from foreign sources, as the sickness and mortality returns of the Registrar-General made no reference to religious or racial factors. Although Dr. Hall has only been able to deal with the Russian type of Jew from the age of 18 to 42, nevertheless his article should lead to much valuable discussion and further study on a subject which is both fascinating and of practical utility.

No doubt it was impossible for Dr. Hall, in the amount of space at his disposal, to go more fully into his subject. Had he been able to do so, his fuller views would have been welcomed on certain defects and diseases which medical literature has shown to be very rare or very common among Jews. The reference is to such conditions as alcoholism, diabetes, gout, myopia, and glaucoma, nerve diseases, surgical tuberculosis, and diseases of the rectum, among other things.

Experience in medical practice, correlated with the experience of others, as gathered from existing literature by those who have had opportunities of studying Jewish morbidity, agrees in many respects with Dr. Hall's conclusions on the racial incidence of disease among Jews. Lack of space prevents entering into many of the causes, apart from what Dr. Hall has already mentioned, that would probably explain the morbid conditions he has outlined in his useful article. There will be dissent, however, from Dr. Hall in certain of his findings. True epilepsy we seldom encounter among Jewish patients, and both Charcot and Worms, from their experiences among hospital patients, point to the rarity of epilepsy in Jews as compared with non-Jews. This rarity may be attributed to the absence of the predisposing factors of syphilis and alcoholism in Jewish parents. The diet of the Russian Jew is excessive in starch, because of the habit cultivated from their Slav neighbours of eating an excessive amount of bread, but Dr. Hall's remarks that the Russian Jewish dietary is deficient in proteins and contained fats which were vitamine-free will be challenged. Reports of investigators in vitamins—e.g., Mellanby,¹ and personal experience in Jewish dietaries, disagree with Dr. Hall's observations.

¹ THE LANCET, April 17th, 1920.

Though it must be confessed that venereal disease is on the increase among Jews, yet statistics everywhere point to the fact that organic nervous diseases and the dermatoses secondary to syphilis are much less frequent in the Jewish race than among the general population. It might also be mentioned that circumcision in the Jew does away with the evils that result from phimosis and paraphimosis, lessening also the likelihood to infection by syphilis (Breitenstein's statistics prove that syphilis is five times as frequent in the uncircumcised—the immunity is said to result from the toughening of the exposed glans), and accounts for the fact that not a single case of carcinoma of the penis in a Jew has yet been recorded.

I am, Sir, yours faithfully,
SAMUEL SAMUEL, M.D., M.R.C.S.,
Late Captain, R.A.M.C., Honorary Medical Staff,
Leeds Jewish Hospital.
June 12th, 1920.

ANGLO-AMERICAN LIBRARY FOR CENTRAL EUROPE.

To the Editor of THE LANCET.

SIR,—Would not the above undertaking, noticed by you a while back, be now more useful if it functioned merely as an exchange of scientific and other literature between the countries concerned? The immediate reason is the unsatisfactory working of existing agencies. In my own case H.M. Stationery Office is now very irregular in its deliveries, while a leading book importer has for months not been able to fulfil an order for the whole war-time issue of a Vienna medical magazine, in spite of the offer of a fair price for the same instead of the exchange rate. The remote reasons are the (mostly silent) change in informed persons' opinions as to the origin and conduct of the war, the result of the partial removal of the censorship—a change expressed by Mr. Chesterton in the epigram that all that thought itself on a pedestal now finds itself up a tree—and the even greater alteration in British opinion concerning Freud's work; it is not so long since some medical journals here—not, I think, THE LANCET—allowed the late Dr. Mercier to write in their columns of psychoanalysis as fraud and pornography.

I am, Sir, yours faithfully,
CADUCEUS.
June 26th, 1920.

DR. JOHNSON AND SECOND SIGHT.

To the Editor of THE LANCET.

SIR,—In the *Cornhill Magazine* for the current month Mr. Edward Clodd discourses in his usual pleasant fashion upon the subject of Dr. Johnson and the phenomenon generally known as "second sight," though it ought to be called, as Mr. Clodd points out, "two sights"—i.e., the one of the world of sense and the other of the world of spirit. Belief in this double sight is as old as human history, and in my opinion cannot in any general way be ascribed to diseased mentality. Even the wisest of us understand but little of the workings of the mind, and the belief that there is a spiritual world to appreciate which the eye may be sometimes opened is nearly universal, and not at all confined to any over-imaginative or readily credulous section of the people. "Second sight" in common parlance means the power possessed by some persons of foretelling the approaching death of others by seeing them shrouded to a greater or less extent, according as their death is imminent or the reverse. Mr. Clodd says "One of the earliest references in this matter is given in the 'Polychronicon' of Ranulf Higden." I presume that he means one of the earliest as regards the belief in the Scottish Isles, for, of course, the earliest and far best known instance on record is the vision of Theoclymenus in the *Odyssey*, Bk. XX., of the approaching death of the suitors. Other portents of death seen by the second sighted and quoted by Mr. Clodd include visions of black dogs, funerals, and corpse candles. These matters Andrew Lang explained by assuming that such manifestations are merely a kind of aphasia from which spirits suffer owing to their not possessing any mitter through which they can make their wishes or ideas

manifest. For instance, in the story entitled "In Castle Perilous," Lang makes a communicative spectre explain that the Puddifant ghost "has been trying for generations to inform his descendants that the drainage of the castle is execrable. Yet he never can come nearer what he means than taking the form of a shadowy hearse-and-four and driving round and round Castle Puddifant at midnight."

To return to Dr. Johnson, he was willing to believe in second sight, but does not seem to have found altogether convincing evidence, although he told Boswell in a discussion on the matter that instances of fulfilment of such omens "have happened so often that mankind have agreed to think them not fortuitous." As with so many other matters, the worst that can be said against second sight in the restricted meaning of premonition of death is, we think, "not proven," while if there were no belief in supersensual things, music, poetry, and painting would scarcely exist. Handel and Blake with their "multitude of angels," Ruskin and Newman with their vision of natural phenomena as the fringes of God's garment, Traherne with his poems on childhood, are all examples of this; while in other literature, to take only one example, there is the intensely dramatic scene in the Second Book of Kings when the King of Syria sent an army to arrest Elisha and "the Lord opened the eyes of the young man; and he saw, and behold, the mountain was full of horses and chariots of fire round about Elisha."—I am, Sir, yours faithfully,

June 22nd, 1920.

M.D.

THE STANDARDISATION OF COLOUR PERCEPTIONS.—This correspondence is closed. A further letter, received by us from Mr. J. H. Parsons, has not been inserted as Mr. Parsons has already announced his intention of dealing with Dr. Edridge-Green's position elsewhere in detail.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At examinations for medical and surgical degree held in Easter term the following candidates were successful:—

THIRD EXAMINATION.

Part I., Surgery and Midwifery.—L. W. Batten, Sidney Sussex; W. L. Berry, Caius; P. F. Bishop, Clare; H. J. Bower and J. H. Burn, Emmanuel; W. F. Castle, Trinity; P. D. H. Chapman, Sidney Sussex; V. M. Coates and H. E. Creswell, Caius; H. T. Cubbon, St. John's; L. Cunningham, Downing; W. D. Doherty, King's; C. C. R. Downing, Pembroke; N. D. Dunscombe, Downing; J. Fairbrother, Caius; V. N. Fenton, Queen's; D. G. Garnett, Pembroke; C. I. C. Gill, King's; A. C. V. Gosset, C. Grantham-Hill, and E. A. H. Grylls, Caius; G. Habgood, Clare; A. C. Halliwell, Caius; F. R. G. Heif, Sidney Sussex; J. M. Higginton, St. John's; H. W. Leatham, Trinity; A. A. Lees, Emmanuel; E. E. Llewellyn, Christ's; F. S. Maclean, Jesus; E. C. Malden and L. B. Maxwell, Caius; J. W. McK. Nicholl, Queen's; C. C. Okell, St. John's; C. L. Pasricha, Caius; R. Y. Paton, Trinity; K. Playfair, Caius; H. J. A. Pollard, Clare; J. L. Potts, Caius; W. Raffle, St. John's; W. F. Rhodes, H. Selwyn; H. A. Richards, Clare; P. Richardson, Christ's; A. P. Saint, Downing; F. N. Sidebotham, Clare; F. V. Squires and H. N. Stafford, Caius; S. D. Sturton, Emmanuel; M. B. R. Swann, Caius; W. S. Sykes, Emmanuel; K. H. Tallerman, Caius; W. S. R. Thomas, Queen's; G. S. Trower, King's; W. G. Verniquet, Emmanuel; G. H. Ward and G. C. Wells-Cole, Caius; R. C. P. Whitcombe, King's; and J. M. McC. Wright, Pembroke.

Part II., Medicine, Pathology, and Pharmacology.—W. E. H. Banks, Clare; H. Barbash, St. John's; L. W. Batten, Sidney Sussex; W. L. Berry, Caius; J. H. Burn, Emmanuel; W. F. Castle, Trinity; M. T. Clegg, Jesus; C. B. Cohen, Trinity; C. C. R. Downing, Pembroke; H. S. Evans, Trinity; L. P. Garrod, King's; W. N. Goldschmidt, Pembroke; E. F. S. Gordon, St. John's; A. C. Halliwell, Caius; F. R. G. Heif, Sidney Sussex; E. P. Hicks, Trinity; J. M. Higginton, St. John's; R. Hilton, Corpus Christi; R. Lester Williams, St. John's; P. T. Liang, Caius; R. K. Merson, Emmanuel; F. Moor, Trinity; C. C. Okell, St. John's; F. P. N. Parsons, Pembroke; R. A. W. Procter, Clare; W. F. Rhodes, H. Selwyn; M. K. Robertson, Trinity; C. J. Scholtz, Emmanuel; C. G. Schurr and R. S. Scott, Caius; W. J. D. Smyth, Pembroke; F. G. Spear, Christ's; C. Suffern, Emmanuel; M. B. R. Swann, Caius; W. S. R. Thomas, Queen's; G. S. Trower, King's; E. W. Todd, Trinity; E. B. Verney, Downing; W. G. Verniquet, Emmanuel; T. T. B. Watson, Christ's; J. M. McC. Wright, Pembroke; and H. B. Yates, Downing.

UNIVERSITY OF OXFORD.—At examinations held recently the following candidates were successful:—

SECOND EXAMINATION FOR DEGREE OF BACHELOR OF MEDICINE. *Materia Medica and Pharmacology*.—C. W. C. Bain, Christ Church; J. L. Cox, Brasenose; R. S. Creed, Trinity; D. G. T. K.

Cross, St. John's; D. G. Davies, Magdalen; C. F. T. East, New; S. Hartley and H. C. Hill, Hertford; B. W. Williams, Exeter; and W. A. Young, Jesus.

Pathology.—D. G. T. K. Cross, St. John's; I. Harris, Jesus; S. Hartley, Hertford; T. S. Nelson, University; and W. F. Skaife, Trinity.

Forensic Medicine and Public Health.—C. K. J. Hamilton, Lincoln; W. E. Hayes, New; J. T. S. Hoey, Jesus; J. G. Johnstone, St. John's; E. G. M. T. Liddell, Trinity; T. S. Nelson, University; H. L. Rayner, Balliol; G. H. Rosedale, Merton; W. F. Skaife, Trinity; and W. S. Tunbridge, Lincoln.

Medicine, Surgery, and Midwifery.—H. E. A. Boldero, Trinity; H. G. Burford, Christ Church; and T. S. Nelson, University.

MASTER OF SURGERY.

W. H. Ogilvie, New; and N. A. Sprott, Christ Church.

DIPLOMA IN PUBLIC HEALTH.

Part I.—T. C. Backhouse, M. S. Baker, A. R. Balmain, L. W. Barlow, F. E. Bendix, C. K. Carroll, R. J. W. A. Cushing, S. C. Davidson, F. W. Kemp, C. Kingstone, T. J. Lloyd, H. R. Macintyre, J. S. Moore, M. Radford, W. C. Sawers, C. W. Sharpley, D. C. Suttie, and A. E. Woods.

Part II.—J. N. L. Blamey, A. R. Balmain, F. W. Hamilton, H. R. Macintyre, L. J. J. Orpen, W. C. Sawers, D. C. Suttie, C. H. Warner, and E. A. Woods.

UNIVERSITY OF MANCHESTER.—The following recommendations have been approved for the degree of Doctor of Medicine (by dissertation):

J. G. Bennett, R. B. Berry, Mary G. Cardwell, J. W. Crawshaw, Jacob Holker (Gold Medal), R. C. Hutchinson, E. A. Linnel (commended), A. H. Macklin (commended), R. A. Needham and F. C. Ormerod (commended).

UNIVERSITY OF GLASGOW: COMMEMORATION DAY DEGREES.—On Thursday, in last week, the degree of Doctor of Laws was conferred by the University upon, among others, Dr. John Macintyre, Glasgow; Sir Robert W. Philip, Edinburgh; and Lieutenant-General Sir David Henderson, Director-General, League of Red Cross Societies.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: A ROYAL FELLOW.—The Duke of Connaught, accompanied by Sir Malcolm Murray and Sir Edward Worthington, paid a visit to the Royal College of Surgeons on June 24th to receive the diploma of Honorary Fellow. His Royal Highness was received by the President (Sir George Makins), the Vice-Presidents (Sir Anthony A. Bowlby and Sir John Bland-Sutton), and the Secretary (Mr. S. Forrest Cowell) and conducted to the Council Room, where the members of Council were assembled, together with Sir John Goodwin, Director-General of Army Medical Services, and Lieutenant-General Sir George Macdonogh, Adjutant-General to the Forces. The President, in presenting the diploma, referred to the association of His Royal Highness with the medical profession as Colonel-in-Chief of the Royal Army Medical Corps, and mentioned that King Edward, when Prince of Wales, was the first to become an honorary Fellow of the College and that King George had also become an honorary Fellow when Prince of Wales. His Royal Highness expressed his pleasure at becoming an honorary Fellow and signed the roll. A visit was afterwards paid to the Museum, where the President and Professor Keith showed some of the specimens from the War Office collection of pathological specimens and other objects of interest.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—The following candidates have passed the Final Dental Examination and have been granted the diploma of L.D.S., R.C.S. Edin.:

Margaret Peterkin, Alexander Glen Thom, Ernest Purves Thomson, Thomas Archibald Hall, Johannes Vlok Basson, John Lawson Gibson, and Willem Frederik Pauw.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on June 23rd, with Sir Francis H. Champneys in the chair, when a letter was considered from the Carlisle District Nursing Association urging the desirability of holders of the C.M.B. certificate being required to practise midwifery for a period after their training. The Board decided to inform the Association that it appreciates the difficulties which arise from the fact that many midwives do not practise as such, and that it will take all opportunities which present themselves of improving the condition of things in this respect.—A letter was considered from the Ministry of Health enclosing a revised scale of fees which the Ministry proposes to prescribe for payments by local supervising authorities to doctors called in by midwives under Section 14 of the Midwives Act, 1918, and suggested alterations in Rule E. 20 to 23 bringing them more into conformity with Section 14 of the Midwives Act, 1918.—The question of a representation to the Ministry of Health with regard to the expediency of modifying the constitution of the Board was considered; the Board directed that a representation be made to the Minister of Health under Section 1 (1) of the Midwives Act, 1918, that it is expedient to modify the constitution of the Board.

LITERARY INTELLIGENCE.—Messrs. W. B. Saunders Company, Ltd., of London and Philadelphia, have just issued a new and well-printed list of publications amounting to 84 pages, with an index of authors and subjects and a résumé of new books on the back cover. The prices in the book are quoted in dollars, but an inset list is attached giving the prices in English money. A significant note is appended that "owing to the instability of conditions governing book manufacture the prices quoted are subject to change without notice."

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual general meeting of this society will be held at the West London Hospital on Friday, July 9th, at 5 p.m., with Dr. Herbert Chambers, the President, in the chair. The annual report of the council will be presented, also financial statements from the treasurer and editorial secretary, and officers for 1920-21 will be elected. Members who have not already paid their subscriptions are requested to send them without delay to the acting honorary treasurer, Dr. Arthur Saunders, 37, Harley-street, London, W.1.

SOCIETY FOR THE STUDY OF INEBRIETY.—A meeting of this society will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on July 13th, at 4 p.m., when Mr. Arthur Evans will open a discussion on "Alcohol and Alcoholism in Relation to Venereal Disease." Members and Associates may introduce visitors. Subscriptions for the session 1920-21 should be forwarded as soon as possible to the honorary treasurer, Mr. Arthur Evans, 28, Devonshire-place, London, W.1.

MEDICO-LEGAL SOCIETY.—The annual general meeting of this society will be held at 11, Chandos-street, London, W., on July 6th, at 8.30 p.m., when the officers for the ensuing year will be elected, and the report of the honorary secretaries, Mr. Ernest Goddard and Dr. Bernard H. Spilsbury, as well as that of the honorary treasurer, Mr. Walter Schroder, will be presented. At the conclusion of the meeting Dr. Josiah Oldfield will read a paper entitled, *The Suicide Idea and Capital Punishment*.

RESEARCH DEFENCE SOCIETY.—The annual general meeting of this society was held on June 3rd at 11, Chandos-street, London, W., when an address on *Vitamins in their Relation to Health* was given by Colonel R. J. McCarrison. The report of the committee states that several addresses, lantern lectures, and public debates have been arranged during the year, and that new editions of many pamphlets and leaflets have been required; a series of articles by members of the society has appeared in the *Daily Mail*. Dr. Andrew Balfour, Dr. Thomas Lewis, Professor W. M. Bayliss, and Dr. A. Drury have joined the committee of the society. The report of the honorary treasurer shows a satisfactory financial position, but in view of increasing expenditure and the desirability of extended activities, more members are needed.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.—At a meeting of this society on May 12th Dr. R. Huerre read a paper on *Ipecacuanhic Acid in Ipecacuanha and Deëmetised Ipecacuanha*. His conclusions were as follows: (1) The total amount of ipecacuanhic acid contained in ipecacuanha powder was found in the official preparations of ipecacuanha; (2) the de-alkaloidisation of ipecacuanha in order to obtain a deëmetised preparation of ipecacuanha produced a quantitative and qualitative change in ipecacuanhic acid; preparations of deëmetised ipecacuanha contained ammoniacal salts. In a paper on the *Treatment of Post-influenza Insomnia* by Passiflora, Dr. H. Leclerc maintained that ordinary hypnotics, such as preparations of opium, chloral, and veronal, should be avoided, and should be replaced by antispasmodics, especially the passion-flower (*Passiflora incarnata* and *Passiflora carulea*). The preparations of passion-flower most frequently used were the fluid extract and the tincture. Dr. Leclerc preferred the tincture, which he ordered in doses of 30-50 drops at bedtime.

ARTIFICIAL EYES FOR EX-SERVICE MEN.—Local War Pensions Committees will supply to ex-Service men who have suffered the loss of an eye on war service with artificial eyes, and the arrangements made by the Optical Appliances Depot, Clifford's Inn, London, E.C.4, are such that no delay ought to be experienced. Applications should in the first instance be made to the Local War Pensions Committee. The depot possesses an immense stock of artificial eyes, and an elaborate matching system enables requirements to be met at short notice. A special staff is engaged upon the different processes of alteration, re-polishing, and re-cutting, every conceivable colour and shape being classified and made available. In most cases the necessary directions have to be given by local surgeons or hospital authorities, to whom a selection of eyes is despatched from the depot, but in exceptional cases arrangements are made for the man to visit the depot.

THE King has granted permission to Mr. Lancelot Edward Barrington-Ward, F.R.C.S. Eng. & Edin., to wear the Insignia of the Fourth Class of the Order of St. Sava, conferred upon him by His Majesty the King of the Serbs, Croats, and Slovenes in recognition of the services which he rendered to the Serbian sick and wounded under the auspices of the Serbian Relief Fund during the late war.

OXFORD OPHTHALMOLOGICAL CONGRESS: ELEVENTH ANNUAL MEETING.—This congress will meet on July 15th and 16th. The proceedings of the meeting will take place in the Department of Human Anatomy in the University Museum, kindly lent for the purpose by Professor Arthur Thomson, and will consist of addresses, demonstrations, a scientific and a commercial museum. The Doyné Memorial lecturer for the year is Mr. F. R. Cross (Bristol), who will lecture on The Nerve Paths and Centres concerned with Sight. The congress will be opened by the Master, Mr. Sydney Stephenson, on July 15th, at 9.45 A.M. Mr. A. S. Percival (Newcastle-on-Tyne) will speak on Light Sense, with some practical deductions drawn from its consideration, and Dr. Van der Hoeve (Leyden) on Eye Symptoms in Tuberosc Sclerosis of the Brain. A discussion on Perimetric Methods will be opened by Dr. Luther C. Peter (Philadelphia), who will limit his remarks to the new methods of perimetry and the types of cases for which they are especially adapted. The following will take part in the discussion, which will be continued after luncheon: Dr. Van der Hoeve, Mr. W. W. Sinclair, Dr. Marx, Dr. S. Holth (Christiania) Mr. E. H. E. Stack, Lieutenant-Colonel R. H. Elliot, Dr. A. Maitland Ramsay, Mr. N. C. Ridley, Lieutenant-Colonel H. Herbert, Dr. W. Hardin Sears (U.S.A.), and Mr. Percival J. Hay. On July 16th, at 10 A.M., Mr. Maurice Barton will read a paper on an Examination of the Eyes of Pit Ponies, particularly with Reference to Miners' Nystagmus, followed by Mr. A. Hugh Thompson, who will speak on Physiological and Glaucoma Cups, and Mr. Rayner D. Batten on Premonitory Symptoms of Glaucoma. The Doyné Memorial Lecture will then be delivered by Mr. Cross, after which Dr. Louis Sambon will speak on Ancient Eye Instruments. At 2.30 P.M. at the Eye Hospital demonstrations will be given by Lieutenant-Colonel H. Herbert, Dr. Holth, Mr. Ridley, Mr. Batten, Mr. Percival, and Lieutenant-Colonel Elliot. The scientific and commercial museums will be open in the Department of Human Anatomy from 9.30 A.M. to 5 P.M. on the 15th, and from 9.30 A.M. to 1.30 P.M. on the 16th. Members who purpose to be present are requested to send the attendance fee (1 guinea) to the honorary secretary, Mr. A. Bernard Cridland, at Salisbury House, Wolverhampton, at their earliest convenience, and at the same time to intimate whether they desire rooms reserved in Keble College, and whether they intend to be present at the annual dinner.

ROYAL VICTORIA HOSPITAL, BELFAST.—Some figures published in the Belfast papers of June 21st are indeed serious to contemplate in respect to the Royal Victoria Hospital, Belfast. At the end of last year there was a deficit of over £5000. Five months of the current year are gone and, up to May 31st last, the total expenditure rose to £24,406. The receipts for the period were £15,956, leaving a deficit of £8450. If to this their initial £5000 indebtedness was added, the hospital finances were on the wrong side by over £13,000. Three wards opened up just before the war to overtake the increased demands for admission, were costing approximately £12,000 per annum. In 1914, the maintenance of the hospital cost £17,500, while it was estimated that for the current year £55,000 would be required. The hospital was costing more money than ever for its upkeep, and new departments—whose maintenance was an increased charge—had been initiated as the direct result of the war, and, as the treasurer put it, the financial position of the hospital was, comparatively speaking, worse to-day than at any time during its long history. The middle classes, who so loyally supported the institution in the past, cannot now, with their enormously increased financial burdens, do so, and unless the employers and workers subscribed more liberally the hospital will have to be curtailed in its work. The working classes by their subscriptions last year paid for the upkeep of only 96 beds (i.e., £12,500), and the employers by their contributions supported simply 65 beds. The hospital is a magnificent insurance for both employers and employed, and both—who have financially made so much of late in Belfast—will have to contribute far more. For over half a century those of the working classes who have contributed a penny weekly (say 4s. 4d. a year) to the Royal Victoria Hospital, Belfast, have received in exchange the very best medical, surgical, and specialised advice in both extern and intern departments (except in the case of tuberculosis and zymotic and mental disease), and yet they have not individually increased their rate of subscriptions. In the serious circumstances the honorary treasurer appeals to both the working classes and the firms in Belfast to double their contributions.

DEATH OF MRS. MERCIER CLEMENTS.—The medical profession in the north of Ireland has suffered a personal loss in the death from encephalitis lethargica, on June 24th, of Mrs. Mercier Clements, wife of Dr. R. G. Mercier Clements, recently returned as a member of the Belfast City Council. Mrs. Mercier Clements was a well-known figure in public philanthropic work. An admirable speaker, she was closely identified with temperance work and maternity and rescue organisations. During the war she acted as honorary secretary of the unemployment scheme in Ulster.

COMMEMORATION DAY AT LIVINGSTONE COLLEGE.—A successful commemoration day, the first for five years, was held at Livingstone College (Leyton, London, E.) on June 25th. The Bishop of Chelmsford, who presided, based his plea for financial support on the proved economy of giving to missionary workers a short medical training. Time and money were thrown away if a man was sent thousands of miles to die from preventable causes within a few weeks of his arrival. The twenty-fourth session of the College will commence on Oct. 6th, and will be preceded during the last four days of September by a short course of lectures on the personal care of health in the tropics.

IRISH MEDICAL ASSOCIATION.—The annual meeting of the Irish Medical Association was held on June 17th at the Royal College of Surgeons in Ireland, Dr. J. Marshall Day, the President, being in the chair. There was a good attendance. The report of the Council stated that the membership in 1919 increased from 629 to 677. A discussion took place on the remuneration for attendance on members of the Royal Irish Constabulary, and it was decided to advise members of the Association to give three months' notice of resignation of office unless a satisfactory answer was received from the Treasury. A discussion also took place on the question of the remuneration of poor-law medical officers, and it was resolved that without legislation the service would remain unsatisfactory, and that pending legislation the minimum salary should be at least £300 a year. The newly-elected President, Dr. E. Magennis, then delivered an address dealing with the present position of the medical profession in Ireland. In the afternoon the members of the Association, together with a number of other guests, were hospitably entertained at a garden party in the Zoological Gardens by the High Sheriff of Dublin, Dr. J. C. McWalter.

PRESENTATIONS TO MEDICAL MEN.—Dr. S. B. Coates, on his retirement after a service of 42 years as a member of the Belfast Dispensary Service, was recently presented by his medical colleagues with a Celtic silver rose-bowl; while Dr. James Taylor, J.P., dispensary doctor and medical officer of health of Tandragee, co. Armagh, was the recipient of an address in an illuminated album from some 200 friends and patients in Tandragee and the surrounding districts and a wallet of banknotes. Both of these medical men enjoy the respect and confidence not only of their patients and friends, but of the whole body of the profession in the North of Ireland.—Dr. W. Allen Daley, the medical officer of health for Bootle, who will shortly take up a similar position at Blackburn, was presented on July 23rd by the local medical fraternity, with a silver tea and coffee set as a mark of their esteem. In his reply Dr. Daley said that in some towns there was a disposition on the part of medical officers and local practitioners to regard each other as natural enemies. This was not in the interests of public health administration, which, to be successful, should have its foundations in domiciliary work.

FATAL ACCIDENT TO A MEDICAL WOMAN.—The death occurred on June 19th at Bromley, Kent, of Dr. Ethel Amy Mordaunt, following a bicycle accident. While her car which she habitually drove herself, was being repaired, Dr. Mordaunt attempted to do her rounds on a bicycle to which an auto-wheel had been fixed. She had had only one day's experience of its management when she apparently lost control of the machine, and was thrown on to her shoulder sustaining a fracture of the right humerus. Excision of the head was found necessary, and good progress appeared to follow the operation, but the wound became infected, and she died ten days after the accident at the age of 46. Dr. Mordaunt qualified L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg., in 1908, and became M.D. Brux. in 1910, when she set up in practice at Bromley, where she was very well liked. She developed a large and successful practice, and found time to take an interest in local politics. She was a member of the Town Council from 1912 to 1919, and of the Education Committee. Her loss will be widely felt not only by her patients and personal friends but by the Bromley and Chislehurst Maternity Hospital, and many other local institutions and organisations to which she gave so generously of her scanty leisure.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JUNE 22ND.

Sexual Offences Bill.

THE Sexual Offences Bill was committed to a Joint Committee of both Houses, which is considering the Criminal Law Amendment Bill and other Bills.

FRIDAY, JUNE 25TH.

Infantile Mortality in Mesopotamia.

Viscount GOSCHEN, speaking in a general debate on Mesopotamia, initiated by Lord ISLINGTON, said that he had only recently returned from the Middle East. He alluded to the difficulty of getting sufficient labour to develop Mesopotamia, and said that there was a most appalling infantile mortality there among the Arabs. They owed a great debt of gratitude to the British medical men at present in Baghdad, who in the short time they had been there had acted with the greatest vigour, and had tried to deal with this evil by the establishment of hospitals, by research, and by the spread of knowledge among the Arabs. They were endeavouring to induce the Arabs to come to the hospitals. But their efforts must take some time, and meantime there was a great shortage of labour which could only be met by the use of labour-saving appliances.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 23RD.

Pensions for Mothers.

Mr. ROBERT RICHARDSON asked the Minister of Health whether, in view of the opinion of the House that a scheme of pensions for mothers was desirable, he would appoint a committee to inquire into the details of such a measure, with a view to an agreed Bill being introduced at the earliest possible date.—Dr. ADDISON replied: I do not think that any useful purpose would be served by the appointment of a committee such as the honourable Member suggests.

Birth Statistics.

Mr. NEWBOULD asked the Minister of Health whether he could give the number of births in the first quarter of the present year and for the same quarter in previous years, or other figures which would show in a simple form the normal number of births in years before the war, the decrease during the war, and the increase since the war.—Dr. ADDISON replied: The births registered in England and Wales in the first quarters of the last 11 years were:—

1910	1911	1912	1913	1914	1915
221,684	223,585	222,600	216,629	217,414	221,523
1916	1917	1918	1919	1920	
194,565	178,729	162,308	154,920	271,082	

The Finances of Voluntary Hospitals.

Mr. BRIANT asked the Minister of Health if, in the event of grants from public money being made to voluntary hospitals, they would be conditional on the appointment of representatives of the public to the governing bodies.—Dr. ADDISON replied: In the event of any grants being made from public funds for the assistance of the voluntary hospitals, such conditions will be attached to the grants as are necessary to secure that they are properly expended. But I do not think that the honourable Member's suggestion would be effective for this purpose.—Mr. L. MALONE asked the Minister of Health what decisions had been given or what steps had been taken in regard to the acute financial status of many of the London hospitals; whether he was aware that the delay in settling this question was having a very bad effect on the staffs, new recruits hesitating to come forward for training when hospitals were insolvent, and further increasing the strain on the management due to the condition of these affairs; and would he take steps at once to give this matter immediate attention, and also see that necessary action was taken without delay?—Dr. ADDISON replied: As I informed my honourable friend on June 16th, I have given this matter my anxious consideration for some time. The Council of King Edward's Fund have decided to make an immediate distribution of £250,000 to hospitals. The question of the extent to which this grant will require to be supplemented from other sources and the best method of giving such further assistance as is necessary without discouraging voluntary subscriptions is under consideration, but the whole question involves many complex issues, and I am not at present in a position to make any statement.

THURSDAY, JUNE 24TH.

Irish Health Council Report.

Major O'NEILL asked the Chief Secretary to the Lord Lieutenant of Ireland if he could say what progress had been made by the Irish Health Council; and whether they had yet made any report as to the improvement of health conditions in Ireland.—Mr. HENRY (Attorney General for Ireland) replied: I would refer my honourable and gallant friend to the Report of the Public Health Council on the Public Health and Medical Services in Ireland which was presented to the House on June 14th.

Medical Officer of Health for Brecknock.

Mr. SIDNEY ROBINSON asked the Minister of Health whether he was aware that, owing to the delay of his department in granting approval, no medical officer of health and school medical officer had been appointed for the county of Brecknock, and that the health of the county was thereby endangered; whether he was aware that repeated letters and telegrams appealing for sanction to the appointment remained unanswered; and whether he would take steps to expedite the decision in this matter.—Dr. ADDISON replied: I regret that there has been some delay in dealing with this application owing to difficulties regarding the apportionment of the officer's salary among the several offices held by him. There is, however, no reason why he should not forthwith commence his duties, as the Ministry's consent, when given, will have effect from the date on which he commenced his duties. A letter was addressed to the County Council on June 21st.

Parish Medical Officers in the Highlands.

Mr. CATHCART WASON asked the Secretary for Scotland if he was aware of the hard lot of Poor-law medical officers in the Highlands and Islands; and if it was possible for him to make a further grant out of the Highlands and Islands Relief Act, a measure which was specially passed to afford poor parishes adequate relief before the war, and which was infinitely more needed now.—Mr. MUNRO replied: I am aware that parish medical officers in the Highlands and Islands perform a public service often in circumstances of great difficulty. As regards their financial position, I understand that a great improvement, particularly in the less remunerative practices, has been effected by the Highlands and Islands (Medical Service) Grant Act, 1913. The grants payable to practitioners under that Act have been increased to meet conditions caused by the war. I shall be glad to look into any particular case which my honourable friend may wish to lay before me.

FRIDAY, JUNE 25TH.

Blind Persons Bill.

The House went into Committee on the Expenses Resolution of the Blind Persons Bill. The resolution was agreed to by 118 votes to 18.

MONDAY, JUNE 28TH.

Proposed Select Committee on Voluntary Hospitals.

Lieutenant-Colonel RAW asked the Minister of Health if, having regard to the serious position of the voluntary hospitals throughout the country and the consequent prejudicial effect on the national health, he would consider the desirability of appointing a Select Committee of the House to consider what steps, if any, could be taken by Parliament to relieve this serious situation until the new scheme for health services was considered.—Dr. ADDISON replied: No, Sir. I do not consider that at this stage the appointment of a Select Committee is desirable.

Ex-Service Men in Pauper Asylums.

Mr. HURD asked the Prime Minister whether his attention had been called to a resolution of the National Council of the Evangelical Free Churches regarding the incarceration of ex-Service men in pauper asylums; whether any ex-Service men were so incarcerated; and what steps would be taken to secure their treatment in a way commensurate with their service.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied: My right honourable friend's attention had not been called to the resolution referred to, but I may say that any ex-Service man suffering from certifiable insanity who is confined in a county or borough asylum is by special arrangement treated, not as a pauper lunatic, but as a Service patient, if his condition is found to be due to his service in the late war. As a Service patient he is entitled to all the privileges of a private patient, the entire cost of his maintenance and treatment and of the special privileges accorded to him being borne by the Ministry of Pensions. I am satisfied that it would not be in the interests of the men themselves or of their relatives that they should be treated in special establishments devoted exclusively to ex-Service cases. I am, however, taking steps to assure myself that the present arrangements are in all cases working satisfactorily and are the best that can be made in the interests of these unfortunate men.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
SPECIAL NOTICE. (FOR FELLOWS ONLY.)
Wednesday, July 7th.

The ANNUAL GENERAL MEETING of Fellows of the Society will be held in the Barnes Hall at 5 P.M.

Business:

- Election of President and other Officers and Council for 1920-21.
- Annual Report of the Council.
- Annual Report of the Honorary Treasurers.
- Annual Report of the Honorary Librarians.

MEETINGS OF SECTIONS.

Thursday, July 8th.

OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—J. S. Fairbairn, Herbert Williamson): at 8 P.M.

Specimens:

- Mr. Barris: Primary Carcinoma of Fallopian Tube.
- Dr. A. H. Richardson: Fibroma of Ovary with Warty Projections.

Paper:

- Dr. Gordon Ley: The Pathology of Accidental Hemorrhage.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, W. (by permission of the Royal Society of Medicine).

Short Film Demonstrations illustrating Post-Graduate Teaching in Medicine, Surgery and its Specialties will be given on July 5th, 9th, and 12th, by the Fellowship of Medicine, in conjunction with the British Film Institute. Open to all members of the Medical Profession.

MONDAY, July 5th.—5.30 P.M., (1) Major H. C. Marble: Approved Methods, Splints and Appliances for the Treatment of Bone and Joint Injuries.

FRIDAY.—5.30 P.M., (1) (1) Dr. Edward L. Keyes, jun.: Radical Cure of Undescended Testes. (2) Dr. A. Berger: Repair of Fracture of Jaw.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 5th.—2 P.M., Mr. D. Armour: Operations. 2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

TUESDAY.—10 A.M., Dr. Robinson: Gynecological Operations. 2.30 P.M., Mr. Addison: Visit to Surgical Wards.

WEDNESDAY.—2 P.M., Mr. D. Armour: Visit to Surgical Wards. 2.30 P.M., Mr. Addison: Operations.

THURSDAY.—2 P.M., Mr. D. Armour: Operations. 2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

FRIDAY.—2 P.M., Dr. Burnford: Visit to Medical Wards. 2.30 P.M., Mr. T. Gray: Operations.

SATURDAY.—2 P.M., Dr. Beddard: Visit to Medical Wards. Daily.—10 A.M., Ward Visits. 1 P.M., In-patient Clinics and Operations.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, W.C. 1.

MEDICAL SCHOOL.

MONDAY, July 5th.—2-3.30 P.M., Out-patient Clinic: Dr. Collier. 3.30 P.M., Dr. Saunders: Demonstration of Ward Cases.

TUESDAY, July 6th.—2-3.30 P.M., Out-patient Clinic: Dr. Grainger Stewart. 3.30 P.M., Dr. Hinds Howell: Trigeminal Neuralgia.

WEDNESDAY, July 7th.—2 P.M., Dr. Grainger Stewart: Peripheral Nerve Injuries. 3.15 P.M.

THURSDAY, July 8th.—2-3.30 P.M., Out-patient Clinic: Dr. Farquhar Buzzard. 3.30 P.M., Dr. Kinnier Wilson: Demonstration of Ward Cases.

FRIDAY, July 9th.—2-3.30 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Dr. James Taylor: Demonstration of Ward Cases.

Fee for Post-Graduate Course £7 7s. C. M. HINDS HOWELL, Dean.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, July 5th, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhoea by Electrolysis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 5th.—2.30 P.M., Mr. J. B. Banister: Gynecological.

TUESDAY.—9.45 A.M., Lieut.-Col. R. H. Elliot: Selected Eye Cases and Operations. 2.30 P.M., Mr. C. H. Hayton: Laryngological; Dr. J. Metcalfe: Radiology.

WEDNESDAY.—2.30 P.M., Dr. W. J. Oliver: Dermatological.

THURSDAY.—2.30 P.M., Mr. N. Fleming: Ophthalmological. Dr. J. Metcalfe: Radiology.

FRIDAY.—2.30 P.M., Dr. C. E. Sundell: Diseases of Children.

SATURDAY.—3 P.M., Mr. H. W. Carson: Selected Surgical Cases. Daily.—2.30 P.M., Operations, Medical and Surgical Clinics, &c.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.

Post-Graduate Course on Infant and Child Welfare.

TUESDAY, July 6th.—10.30 A.M., Dr. E. Pritchard: Practical Demonstrations on the Management and Feeding of Infants and Young Children—Lecture XI., The Treatment of the Heat Regulating Functions.

THURSDAY.—3 P.M., Lecture XII., The Feeding of Children between Nine Months and Two Years.

UNIVERSITY OF LONDON.

Advanced Lectures in Physiology to Students of the University and others interested in the subject.

A Course of Eight Lectures on the Bio-Chemistry of Sterols will be given in the Physiological Laboratory of the University, South Kensington, S.W.

TUESDAY, July 6th.—5 P.M., Lecture VIII., Mr. J. A. Gardner.

MANCHESTER HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street (behind Whitworth Park).

THURSDAY, July 8th.—4.30 P.M., Dr. N. C. Haring: Ozæna.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

DALEY, W. A., M.D. Lond., D.P.H., has been appointed Medical Officer of Health for Blackburn.

GIBSON, R., M.D., Ch.B. Edin., Honorary Dermatologist, Salford Royal Hospital.

GOTLA, F., L.R.C.P. & S. Edin., L.F.P.S. Glasg., Attending Medical Officer, The Western Dispensary, Rochester Row, S.W.

PEARCE GOULD, E. L., M.D., M.Ch., F.R.C.S., Assistant Surgeon to the Middlesex Hospital.

SHELLEY, R., M.B., B.S. Lond., Assistant Medical Officer to the Middlesex County Council.

SYME, W. S., M.D. Edin., F.R.F.P. & S. Glasg., Surgeon to the Throat and Nose Department, Western Infirmary, Glasgow, and Lecturer on Diseases of the Throat and Nose, Glasgow University.

WOOD, F. T. H., M.D. Lond., D.P.H., Medical Officer of Health for Bootle.

St. Thomas's Hospital: **RUSSELL, H. B., M.B., B.S. Lond., M.R.C.P.**, Resident Assistant Physician; **REECE, L. N., M.B., B.S. Lond., F.R.C.S. Eng.**, Resident Assistant Surgeon; **FOLEY, W. B., M.B., B.S. Lond.**, Resident Orthopedic House Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: **STEVENSON, J., M.B., B.Ch. R.U.I. (Redditch);** **YOUNG, H. G. K., M.R.C.S., L.R.C.P. Lond. (Braintree);** **GALPIN, C. G., M.R.C.S., L.R.C.P. Lond. (Frome).**

Vacancies.

For further information refer to the advertisement columns.

Aberdeen, Rowett Research Institute in Animal Nutrition.—Physiologist. £400.

Battersea General Hospital (Incorporated), Battersea Park, S.W.—Res. M.O. £200.

Benenden National Sanatorium, Kent.—Asst. M.O. £250.

Birmingham General Hospital.—Res. M.O. £155.

Birmingham and Midland Eye Hospital.—Res. S.O. £200.

Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—Res. M.O. £250.

Royal Free Hospital, Gray's Inn-road, W.C.—H.P. and Second H.P. and Anæsth. £50 each. Also Hon. Anæsth. and Asst. S.'s.
Ryde, Royal Isle of Wight County Hospital.—Res. M.O. £250.
St. Leonard's Hospital, 204, Hoxton-street, E.—Third Res. M.O. £325.
St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—H.S. £150.
St. Thomas's Hospital.—Asst. Radiologist. £500.
Salisbury General Infirmary.—H.S. and Asst. H.S. £200 and £150.
Seamen's Hospital, Albert Dock, Connaught-road, E.—H.S. £100.
Sheffield Royal Hospital.—Asst. Cas. O. £150.
Sheffield Royal Infirmary.—H.P. £150.
Sheffield University.—Demonstrator in Anat. £350.
Southampton County Borough.—Asst. M.O.H. £600.
Stafford, Staffordshire General Infirmary.—H.S. £250.
Toowoomba, Queensland, Australia.—Director, Institute of Tropical Medicine. £1200.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. £100.
Warrington Infirmary and Dispensary.—Jun. H.S. £200.
Warrington, Whitecross Institution and Hospital.—Asst. Res. M.O. £300.
West London Hospital, Hammersmith, W.—H.S. and H.P. £50.
Westminster Hospital, Broad Sanctuary, S.W.—H.P. £50. Also Fourth Asst. S.
Wigan Infirmary.—Sen. H.S. £250.
Wolverhampton and Staffordshire General Hospital.—H.S. £200.
Worcestershire County Council.—Asst. County M.O.'s and Sch. Oculist. £500 each.
The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Okehampton, Wymondham, and at Penygroes.

Births, Marriages, and Deaths.

BIRTHS.

PARKINSON.—On the 24th June, the wife of John Parkinson, M.D., 4, Devonshire-place, W.1, of a son.
TASKER.—On June 23rd, at 58, New Cavendish-street, W.1, to Adela, wife of H. L. Tasker, M.D.—a daughter.

MARRIAGES.

ATTERIDGE—COLE.—On June 26th, at the Church of the Sacred Heart, Hampton Wick, Kevin Doyle Atteridge, M.R.C.S., L.R.C.P., to Arbery, second daughter of Mr. and Mrs. Herbert Cole.
BLUETT—CAESAR.—On June 26th, at St. Andrew's, Ashley-place, S.W., Dr. George Mallack Bluett, formerly of Palace-gardens-terrace, to Emily Henrietta, daughter of the late Mr. and Mrs. J. Caesar, of Tunbridge Wells.
BROWN—COPP.—On June 23rd, at S. Andrew's, Willesden Green, Alexander Middleton Brown, M.A., M.D., D.P.H., to Clara Ethel, eldest daughter of Mr. and Mrs. W. Copp, Cricklewood.
MOSSE—WILSON.—On June 23rd, at St. Andrew's Church, Norwich, Colton Grimley Tenison Mosse, M.R.C.S., L.R.C.P., to Florence Evelyn, only daughter of Mr. and Mrs. A. N. Wilson, of Norwich.

DEATHS.

DOVE.—On June 26th, suddenly, at Brightside, Crouch End-hill, Dr. Aug. C. Dove, aged 64.
HIND.—On June 21st, Lieut.-Col. Wheelton Hind, T.D., M.D., F.R.C.S., F.G.S., of Roxeth House, Stoke-on-Trent.
KILNER.—On June 23rd, at Black Gang, Walter John Kilner, M.B., M.R.C.P., of Ladbroke-grove and Bury St. Edmunds, aged 73.

Notes, Short Comments, and Answers to Correspondents.

SOME RACIAL PROBLEMS, SOCIAL EVILS, AND MODERN CRUSADES.¹

By ROBERT B. WILD, M.D., M.Sc., F.R.C.P.,

DEAN OF THE MEDICAL FACULTY, UNIVERSITY OF MANCHESTER, ETC.

THE need for a clear appreciation of the factors involved in racial evolution is shown by many modern movements designed to improve the conditions of life, the welfare of the individual, and to produce a strong and virile race; on every hand there are crusades against predominant diseases, admitted or supposed social evils, and various forms of racial degeneration. One of my former teachers—a great master of medicine—Sir W. Roberts, used to impress upon us as the most important maxim in therapeutics never to order a dose of medicine without considering, “Can it possibly do harm?” This admirable caution is equally advisable before applying remedies to the body-politic as well as to the individual, for we must remember that the present conditions of life are the result of generations of growth and represent a balance of factors which has been slowly arrived at and which may more easily be disturbed than readjusted.

While I am far from wishing to make any attack upon these crusades, and least of all upon the sincere, well-meaning, and often altruistic persons who lead them, I do think it is important to consider their racial as well as their individual effects. The welfare of a particular individual may not always be coincident with the best interests of the nation or race to which he belongs.

The Regeneration of the Race.

The first racial problem which has to be faced is the need of every nation for a due supply of healthy children to replace the wastage of war and its aftermath of disease and starvation. Before the war the falling birth-rate of almost all the more highly civilised nations was a cause of anxiety to many. Possibly an increasing complexity of civilisation with greater demands for the development of the nervous system may have some influence upon the capacity for reproduction. Also the greater demands of social life and the expense and difficulty of maintaining and housing a family tend to raise the age of marriage until a sufficient income is assured with a consequent shortening of the child-bearing period. In many countries also these difficulties lead to the deliberate limitation of families or the procuring of abortion by illegitimate means. It is possible that in the future the community may be driven to protect itself by insisting upon a registration of pregnancy; even now in Scotland under certain circumstances the concealment of pregnancy is an indictable offence.

One of the handicaps which all nations have to carry is the burden of supporting unproductive members of the community or of maintaining during the period of growth and adolescence a number of children who die before they can repay to the nation, by their work, the cost of their rearing and education. Any widespread disease which removes individuals at a time when their working powers are on the wane and before they become a burden on the community is an advantage, and a disease which destroys the individual in early adolescence is a serious handicap.

Tuberculosis and Cancer Contrasted.

The crusade against tuberculosis can do nothing but good. I think, however, that too much is made of the bacillus and too little of the environment; it is pre-eminently a case where preventive medicine has an open field. The great increase of tuberculosis which appears to be so marked a feature in the countries of Central Europe which have suffered most from malnutrition, and its progressive increase as food became less and less plentiful, will, as its special incidence is carefully studied, undoubtedly lead to a better knowledge of its aetiology, and we may find that a deficiency of some vitamin factor in the food is responsible for a decrease in the resisting power of the tissues to the invasion of the tubercle bacillus. In this connexion it is interesting to note a paper by Dr. B. G. M. Baskett,² in which he shows how the death-rate from tuberculosis through a long series of years varies with the rise and fall of real wages, by which he means the relation between the wage paid and the price of food.

¹ Abridged from a Presidential Address delivered before the Manchester Medical Society, Feb. 4th, 1920.

² Brit. Med. Jour., Jan. 10th, 1920.

We may contrast with tuberculosis another disease of great importance—namely, cancer—against which we have also a crusade. Although cancer may attack patients at all ages, the great majority of cases occur in later middle life, when most of the sufferers have already done the greater and most productive part of their life's work. Their deaths at a time when they are likely soon to become a burden on the community lighten the load of unproductive consumers which the community has to carry, and cancer is therefore by no means an unmixed evil so far as the national welfare is concerned. If cancer was found to be curable or preventable to-morrow one of the results would be within a few years an enormous increase in the cost of old-age pensions. Similarly, conditions such as arterio-sclerosis are disastrous for the individual, but not to the race. An increase in the number of those who linger on to die by the slow process of senile decay is not a gain to the nation, and it has been said that “those who are noted as centenarians are rarely noted for anything else.” Mere length of days without corresponding length of service is not a desirable aim from the point of view of racial welfare.

Veneral Disease.

The crusade against venereal disease, though of great benefit to the individual sufferer, may do more harm than good. I do not want to enter to-day into the question of prophylactic packets and cleansing stations, but would merely quote the old tag, “The means at hand to do ill deeds oft makes the ill deeds done.” The true remedy for venereal disease, and also for that other social evil prostitution, is the encouragement of early marriage and the institution of such conditions of living as to facilitate the rearing of a family. Tennyson put his finger on a great evil when he wrote over 60 years ago—

“Cursed be the social wants that sin against the strength of youth
Cursed be the social lies that blind us to the living truth.”

Many years ago I was much struck by the curious fact that venereal disease was particularly widespread in the most highly civilised and advanced nations of the world, and was forced to the conclusion that at any rate racial progress is not incompatible with considerable syphilitic infection. The association of syphilisation with civilisation is probably due to the fact that extensive promiscuity of sexual relations can only take place in comparatively large communities, and it is only in such communities that we find the combination of individuals for mutual defence, mutual help, and specialisation of function, which is the first foundation of civilisation. In a community where the competition is keen the members of it infected by venereal disease—generally speaking those individuals whose passions are strongest and moral control weakest—are at a disadvantage, and in comparison with the non-infected they are likely to leave fewer offspring and these less likely to reach a healthy maturity. Venereal disease therefore, if not too widespread, is not an unmixed evil for the race.

Eugenics.

Another crusade designed to raise the quality of the population is the cultivation of eugenics. As yet, however, any general application of the principle of eugenics is wanting, and it is likely to remain wanting until there is some agreement as to what is the ideal for which it is desirable to breed. The principles of heredity are still largely speculative, but in practice all breeders know that the first requisite for success is to have a clear idea of the object to be attained; for example, we may breed horses or pigeons for speed, flowers for colour or scent. But the aims of the eugenic expert in the regulation of human breeding are not yet agreed on. Some would breed for physical development, some for “the will to power,” some for mental qualities. Among the latter, disagreement soon comes in, for to some the desirable type appears to be the quick alert mind ready to see immediate issues and turn them to practical use; to others the more highly developed intellectuality which works more slowly, takes longer views, and is the basis of scientific progress; while for a third group the progress of the world is bound up in a more highly developed emotional capacity with an advance of the spiritual life towards the religious ideal and of the altruistic as opposed to material interests. It may be possible to breed with more or less success for any one of these ideals, but not for all, and it is futile to expect any general agreement on the choice to be made. There is an old Lancashire saying that “It taks av sorts o’ foke to mak a world,” and probably our present methods of sexual selection give, on the whole, as good results as would be obtained by a more conscious and deliberate method.

Drug Addictions.

I now pass on to another social evil of the widest importance and the subject of endless controversy—that of drug addictions. It is not always easy to say what is a drug addiction or that it is necessarily an evil. For example, the medicinal use of thyroid or the dietetic use of purins or alcohol may lead to habits of which the border is hard to

define. However, I wish to confine myself to a few of the more important drugs, producing either a narcotic or a stimulant action on some part of the central nervous system or the autonomic ganglia. Many hypotheses have been put forward as to how drug addictions arise, and every one of them may be right. I only wish to mention four. The late Dr. Norman Kerr looked upon the addiction to drugs as a definite disease closely allied to insanity, to which he gave the name "narcomania." The late Sir William Roberts classed the narcotics and stimulants in habitual use as "euphoric agents," and put down their employment simply to the pleasurable sensation of well-being which temporarily followed their use. Dr. Harrington Sainsbury says: "We fly to drugs and we initiate habit either to escape a distress of mind or of body, or to secure a pleasure; in some cases both objects are attained." This is often true, but I agree with Herbert Spencer's statement that in many people in a civilised state "the activities are cerebral in a degree beyond that to which the constitution of the race is adapted." To many people even the ordinary tasks of daily life produce a sense of exhaustion, which is temporarily relieved either by a narcotic which dulls the highest perceptive powers or by a stimulant which rouses the over-fatigued brain to additional effort; some find the one method, some the other, the more effective.

At first probably recourse to these drugs is only made to relieve an exceptional strain or a blighting monotony of occupation, but as the indulgence is repeated more and more frequently the habit is acquired and the regular action of morphine, cocaine, alcohol, caffeine, or nicotine becomes essential to that smooth working of the functions of the body which gives rise to the feeling of euphoria or well-being. A stopping of the habitual drug is like the stopping of the lubricant in a machine; there is in working friction instead of smoothness, and the result of the disturbed functional activities is that severe symptom-complex of deprivation which we know as a "craving," and which leads to a larger dose of the drug by which the symptoms are quickly relieved. Thus the victim is led deeper and deeper into the power of the drug until all interest in life beyond that of satisfying his craving is gone, and to do this successfully he counts the world well lost. When this stage is reached his or her value as a citizen is gone, and, though it may seem a hard saying, the community is best served by his early death.

Of the narcotic drugs by far the most important is alcohol. The high-water mark of alcoholic consumption in this country—one of the highest in the world—was reached in 1900, when the estimate per head of total population was 32 gallons of beer, 1·22 gallons of proof spirits, and 0·42 gallons of wine. In 1913, the last full year before the war, it had fallen to 27 of beer, 0·67 of spirits, and 0·24 of wine. Later statistics are of no value as they are vitiated by variations in the alcoholic strength and the absence from the country of so large a proportion of men. It is now proved that alcohol is not a stimulant but a selective narcotic, which paralyses certain centres earlier than others, notably the centres for the perception of pain and discomfort, whether bodily or mental, and also the centres of inhibition.

Of the evil effects of the abuse of alcohol there is no need to speak, but we may ask whether there are any compensating advantages to the moderate users? First, of course, there is some food value. Alcohol can replace a considerable proportion of the carbohydrates and fats of the food, and it may also aid appetite and digestion, and enable otherwise unpalatable food to be enjoyed. In many monotonous occupations, and in times of stress, alcohol can enable work to be carried on for a time which would otherwise be impossible. It will, when taken after work, afford relaxation to the mind and promote a feeling of euphoria. It makes many men contented with their work who would otherwise rebel. One result of its action on the brain is by relaxing inhibition to promote freer social intercourse and mutual coöperation. It is not for nothing that dinners play so large a part in raising funds for charitable objects.

The Effect of Alcohol on the Race.

As regards the effect of alcohol upon the race it was long ago said that "alcohol was nature's finest sieve for the sifting of the fit from the unfit," and we can easily see that the consumers of alcohol are handicapped in the race for the highest places. First, there is the economic handicap, for as a food alcohol is expensive, and those who buy it have the less to spend on other necessities which may be to their advantage. Secondly, though it may enable men to do work which they could not do without its aid, yet work done under its influence is less perfectly done, and they fail to reach the highest standard. Thirdly, those who from lack of self-control give way to excess in its use fall lower and lower in the social scale. As the pronounced alcoholic families tend also to die out in the course of a few generations, we can see that the indefinite continuance of the race is continued in the main by those members of the nation who are able to withstand the temptations of alcohol. Whether these and possibly other advantages outweigh the loss to the com-

munity, occasioned by the incapacity, sickness, and early death of those who take excess, must be a matter of individual opinion, but we shall all, before long, have to act upon our convictions as to whether the use of alcohol in this country shall be prohibited or allowed. Meanwhile, we shall all watch with the greatest interest the experiment now on trial in America. I doubt whether prohibition in this country would deprive the habitual alcoholic of his stimulant. We have had for some years a prohibition as close as possible of opium, morphia, and cocaine, and yet we find a considerable number of victims to these drugs. Where a law is opposed to the feelings of any large number of the community it is certain to be evaded, as in the old days when smuggling carried with it but little social stigma, and few people scrupled to take advantage of smuggled goods when they had the chance; a somewhat similar and recent example of the same kind is the law passed a few years ago to restrain juvenile smoking, and we all know the futility of the law designed to prevent unqualified dental practice. Any law which is evaded is worse than none, as its evasion produces a general lowering of that respect for law which is the basis of government.

I should like to quote you the conclusions arrived at by Dr. Harrington Sainsbury in his book on "Drugs and the Drug Habit"; he says:—

"For the principle of local option there is much to be adduced, but when all is said and done it is a tyranny—the tyranny of a majority, and when there is a bare preponderance it may be an unjustifiable tyranny. May it therefore be commended to the prohibitionist or abolitionist: 1. That temperance promises a higher moral yield than total abstinence. 2. That the aim of all education should be to develop character, to create a people strong-willed for good. 3. That it is possible to pay too high a price for sobriety and that this excessive price is paid when liberty of action is forfeited."

Of all narcotics ethyl alcohol is the least harmful, and we have already had evidence that its prohibition is likely to be followed by a resort to more harmful drugs.

Other Drugs.

Opium and morphia are the cause of even more serious results to the individual, but the number affected in this country is too small to have any appreciable effect on the race. Indian hemp, either as hashisch, gunja, or churrus, has never taken root in England, but it is widely used in our Asiatic dependencies and the neighbouring countries, and produces effects which are in some respects intermediate between those of alcohol and opium, with a marked tendency to cause insanity.

Of the other narcotics which give rise to habit I will only mention chloral hydrate, veronal, and sulphonal. It is less commonly known that acetanilide, in the form of headache powders, may give rise to a habit, and that aspirin is becoming increasingly popular as a pick-me-up. What the consequences of habitual aspirin taking may eventually be I do not know, as it is only of recent development, but I have seen cases of distinct craving for it. I want especially to call attention to this class of drugs, as the habit of taking them seems to be on the increase of late years, and the interesting point arises as to whether there is any connexion between this increase and the decrease in the consumption of alcohol since 1900.

Of nerve stimulants cocaine is probably the worst drug addiction we have to deal with. It is a direct stimulant to the brain, and the sense of euphoria produced is more intense than that produced by any other drug, hence its great seductive power. I have seen many cases, and three past students of my own either committed suicide or had to be sent to an asylum as a result of cocaine. The oxy-purin bases, caffeine, theobromine, and theocine, are so closely allied to the food constituents and so universally taken that many people do not recognise that they are taking drugs at all, and, moreover, they are drugs of comparatively recent introduction to our race. It is also worth noting that allied purin compounds, such as xanthin, hypoxanthin, and guanin, are present in considerable quantity in meat extracts, which are also coming more into use as popular stimulants and beverages. Physiologically the effects of a cup of beef tea or bovril is almost identical in kind with the effects of a cup of tea or coffee or cocoa.

It is an interesting subject of speculation how mankind in so many parts of the world has discovered and used the oxy-purin alkaloids, as the plants containing them have no characteristic smell or taste which might betray their presence to uncivilised people, and yet we find them in use all over the tropical parts of the world where perhaps the exhaustion produced by excessive heat is best relieved by a nerve stimulant. These bases are pure cerebral stimulants, especially to the intellectual faculties, they remove the sense of fatigue, and often enable work to be done under adverse conditions. Unlike alcohol, they do not impair the quality of the work.

Are there any bad effects to set off against these benefits? There is the possibility that by allowing work to be continued when the feeling of fatigue is an indication that rest is urgently required may lead to a nervous breakdown. Many

authorities also consider that the coincidence of a large increase of functional nervous diseases, especially neurasthenia, with the increased consumption of tea is more than a coincidence. Also a persistent high blood pressure often said to result in early arterio-sclerosis. Of the bad effects of excessive tea and coffee drinking we have all had experience, and I have seen several cases of acute poisoning with intense restlessness, garrulity, and absence of sleep, with a pulse of 160, followed by extreme exhaustion.

Another drug addiction is that of nicotine, next to caffeine the most universal of all, and which is also the subject of a crusade, which apparently makes little headway.

Conclusion.

Probably neither caffeine nor nicotine is a serious handicap to the nation at present, for our competitive nations are equally affected by these addictions. If the use of these drugs enables more and better work to be done and diminishes the dependence of old age by an earlier wearing out of the arterial tissues the nation will gain at the cost of the individual, and in peace as in war the welfare of the individual should be sacrificed for the good of the race.

In trying to bring before you some of the problems with which we are faced at the present time I suggest that it is necessary for us as medical men to take a broad and unsentimental view of the issues which will confront us in our work. If in the future the work of a medical man is to be more preventive than curative he will have to think more of the community and of the race than he has done in the past without thinking less of the individual.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL: THE PUPILS' REGISTER.

THOSE who are interested in the hospital and school will be glad to hear that their register is now ready for the press, and the Dean will be glad if anyone who wishes to subscribe for a copy will communicate with him. It is difficult at the present time to give any indication as to how much the book will cost, but it seems impossible to expect that it can be published at less than one guinea and it may very likely cost 30s. The book consists of a transcription of all the names (6500 in all) on the pupils' register from 1752 to 1918, with annotation notes on the men about whom it has been possible to find out anything. Among the famous names included in the work will be found those of John Hunter, Mathew Baillie, Thomas and Robert Keate, Sir Benjamin Brodie, Sir Prescott Hewett, Henry Gray, Frank Buckland, Edward Jenner, Sir Everard Home, and the two Gunnings; among those St. George's pupils whose names are not so likely to be known as alumni of the old school occur the names of Thomas Addison, Bence-Jones, John Gale Jones (the political agitator at the time of the French Revolution), Charles and George Hawkins, H. W. Bellew, and Aloyse Sprenger. It is hoped that it will be possible to reproduce photographic representations of the entry cards of old pupils, of which the school possesses a very complete collection of the various types of cards issued at different times, and also the house surgeon's certificate of 1769, presented to Thomas Keate by the board of governors. Dr. G. C. Peachey has written a foreword on medical education in the metropolis during the eighteenth century, in which he incorporates the names of those early pupils of the hospital whose names are to be found in the minutes of the weekly board, with annotation notes on many of them. The Dean would be glad to have the names of intending subscribers before the end of the year.

LOCAL SELF-GOVERNMENT AND SANITATION IN BIHAR AND ORISSA, 1918-19.

THE local administrative measures that are now delegated to the municipal and district authorities in the provinces of India are gradually becoming operative on the material and sanitary conditions of the people, who until recently were almost entirely without knowledge of, or interest in, such matters. In Bihar, at the elections of municipal commissioners in the towns, the number of votes recorded in nearly all cases exceeded 60 per cent. of the electorate, and the number of meetings held in most instances fulfilled the statutory requirement. Progress in action is, however, slow, and the Lieutenant-Governor regrets to note the apathy in many municipalities, of which 46 out of a total of 56 now possess autonomy. In Patna, however, the chief city of the province, which has a population of over 136,000, there was a marked change, the elections being hotly contested. The incidence of taxation in the province averages 1 rupee 12 annas per head (say, 2s. 4d.), which cannot be considered excessive; the expenditure on conservancy operations amounted to Rs. 875,015 (say, £58,334). It is unfortunate that there should be a dearth of men qualified to hold the appointment of health officer: out of 12 municipalities, for which the Government have undertaken to pay the full cost of the appointment, only 6 possess this necessary officer. It is hoped that shortly improved conditions may be offered to properly qualified men. In the rural areas of the province the growth of self-government is

naturally slower; it depends, first, on the extension of the elective system to local boards; and, secondly, on the formation of "union committees," which have power to enforce adequate measures for the preservation of the public health. The efficiency of these committees "depends largely on the existence of a public spirit, which is as yet less common than it ought to be." *Chi va piano va sano* is probably as true here as elsewhere.

THE DANGEROUS REVOLVER AGAIN.

MANY fatal accidents as well as crimes due to the carrying of revolvers have been chronicled in THE LANCET, and presumably many cases of injury remain unrecorded by the press. The following is a good example of the ownership of pistols by persons who, to put the case mildly, can give no good excuse for carrying or using such weapons. A carman charged with murdering his brother by shooting him was recently acquitted at the Central Criminal Court, and it is possible, if not probable, that his account of the affair was a true one. He said that he was standing drink to his brother, and that having called for five glasses of beer he put his hand in his coat pocket to find a Treasury note wherewith to pay. He "did not know that the revolver was in his pocket," and in pulling it out discharged it, with the fatal result stated. A carman with Treasury notes and a forgotten revolver loose together in the pocket of his coat, and in a public-house, sounds as if he might be dangerous to more than his personal friends. To prevent the carrying of weapons may not be easy; at present it is not unlawful. In the instance cited the man may have failed to have a gun-licence, but subject to that he has been acquitted of manslaughter as well as of murder, and has committed no offence.

LEBANON MENTAL HOSPITAL.

Dr. H. Watson Smith, O.B.E., director of the Lebanon Hospital for Mental Diseases, Syria, states in his annual report that 109 patients (68 men and 41 women) were admitted to the hospital during the year. Thirty-five were discharged cured, 14 improved, 16 did not improve, 8 patients were found to be not insane, and 12 deaths occurred. At the end of March there remained in hospital 85 patients, an increase of 24 over the figures for last year. Recently there has been an increase in the number of acute cases, many of which were soldiers sent by the French military authorities, and in these the results of treatment have been gratifying. The general health of the hospital, Dr. Smith reports, is good, and there is a fairly good supply of food and medicines, but after the war period much is needed for the general improvement and repair of the institution. The London offices of the Lebanon Hospital are at 35, Queen Victoria-street, E.C.

RATS IN HOUSES: SOUTHWICK v. STANTON.

IN an action in the county court a plaintiff claimed damages, alleging a breach by the defendant of an implied condition under the Housing of the Working Classes Act, 1890, and the Housing, Town Planning, &c., Act, 1909, that a house let to him by the defendant was reasonably fit for human habitation. It was alleged that the house was overrun by rats from a neighbouring sewer, which destroyed clothing belonging to the plaintiff, as well as provisions kept by him in a small room, which he used as a shop. The county court judge found as a fact that the house was, owing to the continuous presence of rats, unfit for habitation, and following the old case of *Campbell v. Wenlock*, a case of a house infested by bugs, that the implied condition applied to the whole house, and that there had been a breach of it if any of the rooms were unfit for habitation. The divisional court held that the county court judge was wrong, and that an incursion by rats did not constitute a breach of the defendant's contract under the Housing, Town Planning, &c., Act. The appeal raised points as to the rats having invaded the house from adjoining premises, and not being continuously there, and also as to the use as a shop of the part which they entered. There was another question also as to the extent of the remedy if the house were to be held unfit for habitation. The case, therefore, does not appear to go so far as to say that the presence of rats cannot make a house unfit for human habitation. Apparently, however, their presence must be continuous, and must make itself felt in rooms used for human habitation and not merely as store-rooms or for trade. Rats are more likely to be found as visitors than as continuous inhabitants of any house, but that their presence is highly undesirable from a sanitary point of view there can be no question. Their habits and the various methods for dealing with them are described in a convenient form in Dr. W. J. Howarth's "Report on Rat Repression in the City," commented on in THE LANCET of June 26th, p. 1374.

J. R. (Crawley).—We are afraid the case you mention is of no pathological interest.

M. F.—The Swiss Passport Office is now conveniently situated for doctors at No. 10, Upper Wimpole-street, London, W.1.

The Relation

OF

PRELIMINARY SCIENCE TEACHING TO PATHOLOGY.

An Address introductory to the Discussion on Medical Education at the Annual Meeting of the British Medical Association. Delivered on July 1st.

BY J. LORRAIN SMITH, M.A., M.D. EDIN., F.R.S.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF EDINBURGH.

MR. PRESIDENT AND GENTLEMEN,—The relation of the training in preliminary science to that required in pathology in the medical curriculum is of interest because pathology is in many respects a bridge between the earlier and the later stages. Pathology is anatomical and physiological; it deals with structure and function; in its purview the whole field of abnormalities is included. Without physics and chemistry the development of pathology would be practically impossible. To them the pathologist must resort when he would obtain conceptions and methods for the accurate measurement of living processes. To measure chemical or physical change in the organism is the first step towards a scientific interpretation of the living process.

The student who would become trained in pathology must therefore have a complete knowledge of the elementary principles of physics and chemistry. These sciences serve as an introduction to the whole curriculum, and the courses in these subjects should familiarise the student with fundamental laws and principles on which the whole structure of experimental science is built. The subjects which are taken up during the preliminary period are the foundation for all the later work. It is hopeless to escape from empiricism in medical teaching and practice if we do not take the precaution of beginning the course by a study of physics and chemistry. In the demand for a clear and sufficient introduction to fundamental scientific ideas pathology merely emphasises the claim which is made by all other branches of medicine.

INSTRUCTION IN CHEMISTRY.

The courses in chemistry and physics may well be overtaken to some extent at school, and therefore prior to the medical curriculum. But however we may deal with the general elementary introduction to science, there must remain in the curriculum the chemistry and physics which have direct relation to medicine. This form of chemistry and physics cannot be described as preliminary science. It is the detailed and special study of chemical and physical changes in the substances which are found in relation to metabolism. Physiology, pathology, pharmacology, medicine—each and all constantly require on the part of the student detailed knowledge of the intimate chemistry of metabolism.

Hitherto it has been the practice of the medical schools to include in the courses of physiology, pathology, &c., the chemical instruction required by the particular subject. Recently, however, the plan has been introduced in various schools of giving courses in biochemistry which deal with these problems from the point of view of the chemist. Such courses are valued especially because they give instruction in these metabolic processes in their relation to general chemistry. This the biochemist can teach with a freedom and impressiveness which are of great value in conveying knowledge to the student, and the task of giving instruction of this type is handed over to the biochemist by his grateful colleagues. It is true that it is not the chemical process in itself that is the chief interest to the student of medicine, but the chemical process in relation to the activity of the organ concerned in its production. To take an example: the relation to each other of the various substances which appear in the breaking down of molecules of fat is at the same time a chemical problem and a problem in the physiology of nutrition. Chemical knowledge of the process is the basis

on which the study of the process of nutrition rests. It is, therefore, a natural and appropriate subject for the chemical course, and yet it is doubtful if it can be successfully taught in the preliminary period of the curriculum. It is better that the problems of physiological and pathological chemistry should be taught in relation to the courses of physiology and pathology. It is difficult for the student to realise the bearing of the chemical teaching until he has become familiar with the process in the body, for the understanding of which such knowledge is required. To study the process and its chemistry together is the ideal which we should attempt to reach. Hence we should continue the study of chemistry throughout the curriculum. It should at the beginning have place as a preliminary science, but it should continue to be studied in the later years in its application to the interpretation of normal and abnormal organic processes.

How much chemistry should be taught is a question naturally raised at this point. The end to be kept in view is defined by what I have already said. The chemistry of the introductory period, inorganic and organic, must be continuous with and preparatory to all that is required later to understand the teaching of the biochemist when he deals with the chemical changes in metabolism. It would indeed seem natural, therefore, that the direction of the whole teaching should be in the hands of the biochemist. He should begin in the first year by supplementing, if necessary, the general chemical teaching which the students have received at school, and he should extend the work into the sections of organic chemistry and biochemistry which deal with the physiology and pathology of metabolism. It will be necessary for a chemist with such wide responsibility to continue his teaching through several, and possibly through all, the five years of the curriculum. By the unity and continuity of chemical study which would be secured by such an arrangement the student would acquire at each stage the capacity to apply chemical methods of study and interpretation.

THE TEACHING OF PHYSICS AND BIOLOGY.

A similar arrangement would form an equally appropriate method in the instruction to be given in physics. The argument need not be repeated in detail. An introduction to general elementary physics should be given, and this may be obtained wholly or partly in school before entry on the medical curriculum. As the curriculum proceeds in physiology, pathology, general surgery, the special surgery of the eye, the ear, the application of physical methods in medicine, there arises the necessity for special teaching in light, sound, electricity, heat, X rays, radio-activity, &c. As in the case of chemistry, the teaching of physics in relation to the organism is of interest to the student of medicine primarily because of the organic process with which the physical change is associated; but just as we do not propose to leave the teaching of biochemistry to the physiologist, pathologist, physician, and surgeon, so we should commit the teaching of physics to a biophysicist. Unity and continuity is required as in chemistry. In neither case should there be by this arrangement any additional burden placed on the student. The greatest burden which is put upon him by the present curriculum is that of useless knowledge. Time is wasted if spent on studies the interest of which is allowed to lapse at the end of a particular course or after passing a particular examination. The extended teaching which I have proposed would go far to prevent the neglect of the fundamental sciences which takes place under the more haphazard arrangements now in existence. The teachers responsible for the whole course would easily realise what is required at each stage of the curriculum.

The same argument applies, and with still more force, to the study of biology. Pathology, like other branches of medicine, is a form of applied biology. We are too apt to think of animal biology in a restricted sense, as the science of the normal organism. The science has developed its teaching chiefly in the form of morphological description of structure. It is the anatomical or morphological comparison of various types of animal structure that has constituted a large part of the

teaching of animal biology. This forms the introduction to animal biology for the medical student. The normal human organism is studied in detail in the courses of human anatomy and physiology, and it is on a basis of the knowledge gathered in these three courses that the student begins his study of pathology.

STRUCTURAL AND FUNCTIONAL DEVELOPMENT.

In the study of disease the student has to learn the meaning of abnormal structure and function, and in this he has to work out conceptions which the study of the normal may not have brought into prominence. The development of the organism is studied in normal embryology; but in pathology this becomes the basis and the exposition of congenital disease and maldevelopment. To work out the meaning of maldevelopment we have to make use of the laws of heredity and the transmission of structural or functional characters from parent to offspring, and behind the history of the organism and the history of its structural and functional inheritance lies the problem of growth—the nature of growth and the regulation of it as it is seen in cell growth, organ growth, the growth of the body as a whole. In pathological processes in the body growth is disturbed. Sometimes it is diminished, at other times it is excessive; often the growth which results from pathological conditions is partly beneficial and partly harmful. We have to deal with growth associated with pathological irritants; growth associated with hypertrophy in gland or muscle where there is call for increased work; growth which is of the nature of tumour and which assumes a variety of uncontrolled forms partaking of malignancy and revealing absence of the ordinary regulative factors. Disease may be said in general to lead to destruction and disorganisation of the tissues which it attacks. The disorganisation may be followed by recovery in the stages of which the disturbed structure is reorganised or restored more or less completely. To follow the process of destruction or recovery much important study must be directed to the nexus of the various organs with each other in the unity of life.

The margin of function and structure which each organ provides beyond that which is demanded by the bare necessity of bodily activity provides the field within which disease works. When this margin is cut down a point is reached at which the liver or the kidney or the lung or some other organ becomes inadequate. To interpret the functional value of diseased organs requires constant reference to the structural and functional development of the body. Pathological problems are, in a sense, highly specialised, but again we can escape from empiricism in dealing with them only when we give them shape by relating them to general biology and the general study of the development and organisation of the body, and of the origin and correlation of the various organs of which the body is composed. Pathology will be strengthened and simplified in its teaching if the biologist who gave the students their introduction to the general science also continues the teaching in relation to fundamental problems of pathology.

CONCLUSION.

In general my plea is that the present curriculum is wasteful of the students' time because it gives what may be called a general introduction to the sciences, but leaves it to the later teachers or the students themselves to apply the principles and methods of these sciences in the various branches of medicine; whereas a continuity of teaching would concentrate intellectual effort and would thereby attain with much more certainty the standard of work which the curriculum is designed to reach. We must also remember that the student of medicine should be trained in criticism, and for this all-important part of his training the earlier sciences must assume a considerable part of the responsibility. To be a good practitioner of medicine requires that the doctor must possess not only technical knowledge and skill, but also a broad, sympathetic, tolerant conception of life. To secure this nothing could be better than critical reflection on the fundamental conceptions by which the phenomena of life are interpreted.

Medical Experiences

IN

MACEDONIA AND THE CAUCASUS.

*A Lecture delivered before a meeting of the
Royal Society of Medicine*

By ARTHUR G. PHEAR, C.B., M.D. CANTAB.,
F.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL FREE HOSPITAL; LATE CONSULTING
PHYSICIAN TO THE BRITISH SALONIKA FORCE AND
THE ARMY OF THE BLACK SEA.

MR. PRESIDENT AND GENTLEMEN,—In no other war area can there have been greater wealth of clinical material from the physician's point of view than in Macedonia and the Caucasus, and in this lecture I shall endeavour to give an account of some aspects of the medical work, which was throughout of absorbing interest. The only drawback was the difficulty, owing to stress of work, of making continued observations on a systematic basis, and I must ask the indulgence of the Society for the fragmentary nature of the records in many of the cases I shall have occasion to quote.

HOSPITAL ACCOMMODATION AT THE BASE.

The accommodation in the base area for British sick during the summer of 1918 comprised 15 general hospitals, most of them containing 1560 beds, a few with 2000 beds. In the preceding summer the number of hospitals was nearly as large, additional hospitals having been provided when it became necessary, owing to the difficulties of sea-communication, to modify the policy of evacuation on a large scale to Malta. The large number of beds thus provided was none too great, and often patients had to be discharged to convalescent depôt earlier than one would have wished in order to maintain the necessary reserve of empty beds for fresh convoys.

The hospitals and convalescent depôts were situated away from the town, by the sea or among the hills, in comparatively healthy surroundings. A group of four hospitals, three of which were huddled, were placed at Kalamaria, on a low promontory about 8 kilometres from "Piccadilly Circus," the centre in Salonika, to which all roads converged. One of these hospitals occupied an ideal position overlooking the sea, with an uninterrupted view across the bay to Mount Olympus in the distance, and even on the hottest day relief was afforded by a fresh breeze from the sea, which made its appearance in the early afternoon with unfailing regularity. Here was the section for cases of tuberculosis, which, as a rule, did very well, and one often regretted the necessity of evacuating these cases, in order to provide much needed beds, to less favourable surroundings in Malta or at home. Adjoining this, and on an equally good site, was one of the two hospitals for sick sisters. Another group of hospitals and convalescent depôts was situated high up among the hills, about 16 kilos. from the town, on the plateau immediately below Mount Kotos, a well-wooded mountain of some 4000 feet, which dominated the Salonika district. A couple of hospitals were placed further away across the bay to the south of Salonika, on the promontory of Karabouroun, with communication by water. This was, perhaps, the healthiest of all the sites, as the promontory was swept by sea breezes, the only drawbacks being the complete absence of natural shade and a certain brackishness of the water, which had the effect on newcomers of a mild saline aperient. There was excellent sea-bathing for convalescents, and, in addition to the hospitals, the colony included two C.D.'s and a rest camp. It was necessary to close these hospitals during the winter, owing to their exposed position and difficulties of communication in stormy weather.

Supplementary to the British hospitals there were four general hospitals for Serbs, staffed entirely by British personnel, two of which were near Salonika and two at Vertekop, about two and a half hours' run on the Monastir road, not far from the Serbian front. The fortnightly visits to Vertekop were always interesting, as, owing to temperament or circumstances, or both, the resisting powers of the Serb to disease were on a different level from those of the British, and common diseases frequently presented unusual features; also, one saw examples of conditions, such as scurvy, that were practically unknown among our own troops. The most attractive medical unit in the command was at Stavros, a four hours' journey to the east, on the shores of a sheltered bay with high-wooded mountains rising steeply behind. The tents were pitched by the seashore,

and between them were well-grown plane trees which gave good shade; the water-supply was abundant, and on the fertile soil all kinds of produce were grown for hospital consumption; it was curious that a well-wooded site like this should be practically free from anopheline mosquitoes. Though nominally a field ambulance, the unit was practically on the scale of a stationary hospital. Closely rivalling Stavros in natural beauties was a unit in the opposite direction at Naoussa, beyond Vertekop, where a C.D. was established in connexion with the Serbian hospitals, high up among beech forests on the slope of a mountain which arose behind the dépôt to a height of over 6000 feet. Unfortunately, this was too far away to be used to any large extent by the British, though accommodation was unofficially available for a limited number of officers, and was much appreciated by those who were run down and in need of a holiday.

The Climate of Salonika.

Much has been said in disparagement of the climate at Salonika, but, with all its drawbacks, we might in many respects have been worse off. The heat in the summer was sometimes very trying, especially for those who had to reside in Salonika itself; the hills, which during spring and early summer were covered with a profusion of flowers, towards the end of June became parched and arid and of a monotonous faded yellow aspect, all vegetation being dried up with the exception of patches of the dwarf prickly oak. But, outside the town, the days were few when the heat did not become mitigated in the afternoon by the breeze from the sea, and the nights were usually tolerable. The winter climate was of two kinds—periods of three to five days during which the bitter "Vardar" wind blew from the snow-covered mountains to the north, bringing with it cold rain and a state of indescribable mud, or blizzards of fine driven snow with 20° or more of frost. During these spells transport was a matter of the greatest difficulty, and there was nothing in the climatic conditions to make life attractive except the certain knowledge that in the course of a few days matters would improve, and two or three weeks would follow of perfect weather, practically windless, with cold nights and warm days, when convalescent patients could sit out and enjoy the sunshine.

MALARIA.

The rôle played by the mosquito in shaping the destinies of the British Salonika Force may be partly realised from the fact that the total admissions to hospitals for malaria during the years 1916, '17, and '18 amounted to 161,560. Expressed as a ratio per 1000 troops, this number is equivalent to 1053 per 1000, the ratios for the respective years being: for 1916, 331 per 1000; 1917, 353 per 1000; 1918, 369 per 1000. These figures, large as they are, do not represent the whole incidence of malaria, since they include only admissions to general hospitals, stationary hospitals, and C.C.S.'s. They do not include cases treated at field ambulances and discharged as fit from there, nor cases returning to duty after treatment by regimental M.O.'s, nor do they take into account the numerous instances in which

a ratio per 1000 of strength. It is seen that the first material increase in the number under treatment, representing the earliest fresh infections of the year, was at the end of June, from which date there was a steady rise to a maximum in the beginning of October, followed by an abrupt fall during the latter part of that month and continued through November. The cases responsible for the early part of the flow of the malarial tide are exclusively benign tertian. This is probably due to the fact that subtertian infections die out in the course of the winter, and that from February onwards relapses are generally attributable to the more resistant B.T. parasite. The B.T. relapsing cases act as carriers, from which the mosquitoes become infected as their activity increases in early summer. About the latter part of August the number begins to be appreciably swelled by the inclusion of malignant tertian cases. Coincident with this is a distinct change in clinical type; the severity both of B.T. and M.T. cases is greater, cerebral cases become more frequent, and the death-rate rises. It has been impossible to determine the exact ratio of B.T. to M.T. cases, as such a comparison could only be effected by a complete series of blood examinations: the amount of pathological work entailed by this procedure would have been overwhelming, and in 1917 an order was made that in cases where the diagnosis was clear on clinical grounds blood films were not to be sent to the laboratories. Sufficient data are, however, available to show that the incidence of benign tertian malaria was at its highest in the course of September, and that malignant tertian malaria attained its maximum about four weeks later, by which time there had been a considerable fall in the number of B.T. cases. During the early part of the malarial season the prevailing species of mosquito is *Anopheles maculipennis*. With the appearance of M.T. malaria in August the mosquito ranks are swelled by the addition in large numbers of *Anopheles superpictus*. It might be supposed that there is some causal connexion between the two events, but I am told by Colonel Wenyon that there is no direct evidence that *A. superpictus* possesses any superiority over *A. maculipennis* as a carrier of M.T. infection; both species appear to infect themselves equally readily with M.T. parasites.

Clinical Features.

In attacks of primary B.T. malaria the clinical phenomena usually formed so definite and characteristic a picture as to be recognisable even by those who had had no previous practical knowledge of the disease. But the same cannot be said of the manifestations of subtertian and recurrent malaria, and a very short experience in Macedonia sufficed to bring home the difficulties with which diagnosis might be beset.

In malaria the parasitic invasion, which is a general one, often falls with disproportionate emphasis on some special tissue or organ, thereby producing a symptom-complex which may lead to a remarkable simulation of other forms of disease. Thus cases were admitted with symptoms of an acute enteritis, with frequent watery stools, sometimes feculent, sometimes containing blood and mucus. The clinical resemblance to dysentery might be very close, but no dysenteric organisms were present, and in many cases an examination of the blood disclosed evidence of malaria. The condition yielded rapidly to prompt treatment with quinine, and there is every reason for regarding these as cases of malarial enteritis. In other cases the intestinal symptoms were more severe, the stools being profuse and watery and associated with vomiting, collapse, and cramps, simulating cholera. Other cases were seen of prolonged pyrexia of indeterminate type, in which one or another member of the enteric group was suspected, and it was only after weeks of illness and repeated blood examinations that the nature of the case could be proved by the demonstration of parasites in the peripheral circulation.

Difficulties in Diagnosis.

A mistake made by almost everyone at some stage of his experience was the diagnosis of appendicitis in cases of malaria where initial symptoms of marked pain and tenderness with muscle rigidity in the right iliac region were prominent, and in some of these instances an opportunity was provided by the surgeon of proving, by direct observation, the healthy character of the appendix. The absence of anything like a definite tumour, and the results of blood examination, including differential count of leucocytes, were

FIG. 1.—Malaria.—Weekly admissions shown as a ratio per 1000 troops during the year ending Dec. 31st, 1917.

officers and men with slight attacks carried on without reporting sick. The mortality was at the rate of 2.02 per 1000 troops during 1916, 1.17 per 1000 during 1917, and 1.69 per 1000 during 1918. The last figure is probably too high, as there was an enormous increase in the number of reported deaths from malaria in the earlier part of the influenza epidemic, and the figures undoubtedly include many cases in which death was due, not to malaria, but to influenza or its complications.

The seasonal incidence of the disease is well shown by the accompanying curve (Fig. 1), which is based on the return of weekly admissions during 1917, shown as

the distinguishing criteria in these cases, though it must be allowed that, exceptionally, the simulation of appendicitis was so close that the matter could only be decided by an exploratory laparotomy. Further pitfalls for the unwary were provided by cases of malaria with lumbar pain and a transient hæmaturia, rapidly subsiding under quinine; cases with symptoms of acute nephritis also rapidly controlled by quinine; cases with acute gastric symptoms and hæmatemesis; cases of acute pleurisy with effusion, the fluid sometimes containing blood; cases with acute pulmonary symptoms, cough and copious purulent sputum, often streaked with bright red blood and signs of a patchy consolidation of the lung; cases with acute mental symptoms; cases with coma of abrupt onset, resembling apoplexy; cases with epileptiform fits, or symptoms suggesting a cerebellar or a bulbar lesion; cases simulating meningitis with prostrating headache, head retraction, and rigidity of neck muscles; in an example of this, occurring on a hospital ship and diagnosed as a fulminant form of cerebro-spinal fever, the blood examination showed a heavy infection with B.T. parasites.

It is not intended to discuss the exact pathology of these conditions, nor to make any attempt to define the extent to which the symptoms in some instances may be due to a complication of the initial malarial invasion by an added bacterial infection. What I wish to emphasise is the importance in the first place of not overlooking the malarial factor; and secondly, of giving due weight to this factor in determining the treatment to be adopted.¹

With a widening realisation of the manifold and far-reaching activities of the malaria parasite, there arose an almost inevitable tendency on the part of the clinician to fall into a different error, and, attaching undue weight to probabilities, to arrive too readily at a diagnosis of malaria in doubtful cases. Such diverse post-mortem conditions as cerebral abscess, meningitis, hepatic abscess, gastric ulcer with perforation, appendicitis, were found in cases diagnosed as malaria. These mistakes were sometimes due to lack of thorough examination, and therefore unjustifiable; but, on the whole, it is remarkable that the standard of diagnosis was so high, and serious mistakes were so infrequent, considering the strenuous conditions of work in the hot season when hospitals were crowded and heavy convoys were coming in at short intervals, and bearing in mind that of medical officers arriving in the country there were very few indeed who had any previous experience of tropical diseases.

The difficulties of diagnosis were enhanced in the influenza epidemic when the two infections frequently ran concurrently in the same individual; and the clinical threads became still more tangled when, as happened at one time, a considerable outbreak of sandfly fever was added to the prevailing epidemics of malaria and influenza. There were many difficult cases in which the only proof of malaria lay in the demonstration of the parasite in the blood. An ideal course would have been the examination of a blood film in every case; but with such large numbers this procedure was impossible; and in order to relieve laboratories of unnecessary strain it was ruled that blood films were not to be taken in straightforward cases progressing favourably under quinine treatment. The information afforded by examination of the blood was especially useful in the more chronic forms of malaria with irregular pyrexia, in which there might be long periods without demonstrable parasites in the peripheral blood. The diagnosis in these cases was often proved by repeated blood examinations, resulting sooner or later in a positive finding. In the apyrexial stage the information afforded by a white blood corpuscle count was always valuable, as the combined relative preponderance of large mononuclear cells, with reduction in the total number of white cells, gave a picture which was the reverse of that obtaining in many of the acute inflammatory conditions from which malaria had to be distinguished. Enlargement of the spleen taken by itself was of little help; but a palpable and tender spleen, or tenderness over the splenic area combined with increase upwards of the splenic dullness, was valuable evidence of acute malaria.

After-effects of Malaria.

The after-effects of malaria were numerous, and examples were commonly to be seen not only in the wards of general hospitals but also in the various special departments of the

medical service. In the cardiological department a large proportion of the cases of D.A.H. with unduly sensitive exercise-response were traceable to malaria. In the neurological department, in addition to cases of peripheral or central lesions of the nervous system directly due to malaria, the influence of the disease as a contributory factor in various functional conditions was clearly manifested. In the mental department a majority of the cases under treatment was attributable to the same cause. In an analysis published in THE LANCET of Jan. 3rd by Major A. T. W. Forrester, R.A.M.C., who was latterly in charge of the department, it appears that the commonest type of psychosis following malaria was either some form of mental confusion or depression. The outlook in these, as in other post-malarial psychoses, is favourable, and after a course of treatment it was generally found possible to transfer cases to the general wards, whence they could be sent home by hospital ship as ordinary patients.

No one passing through the malaria wards of any general hospital could fail to be impressed by the large proportion of cachectic cases, with profound anæmia, enlarged spleen, marked wasting, more or less pyrexia, and persistent tachycardia increased on any slight exertion. Very low blood counts were recorded—e.g., 900,000, 880,000, 810,000, and in one case 690,000. Accurate hemoglobin estimations were unfortunately seldom available, as many of the instruments had deteriorated through climatic influences, and the colour readings were not reliable. In some instances the blood picture was of the "pernicious" type, with poikilocytosis, megaloblasts, and a high colour-index. In others the clinical picture was that of pernicious anæmia, + a large spleen, + myelocytes in the blood. In other cases there was an aplastic anæmia with little or no attempt at repair. In two cases at least blood was transfused. One of these, a patient with M.T. malaria and profound anæmia, under the care of Major A. C. Sturrock, R.A.M.C., was transfused twice, 18 ounces of blood being introduced on the first occasion, 24 ounces on the second. Previous to transfusion the patient was going rapidly downhill, and it seemed that a fatal issue could not long be delayed. The immediate effect of the first transfusion was very striking, but it led to no permanent response on the part of the blood-forming tissues, and again the patient lost ground, and a fortnight later was rapidly approaching his former condition. The second transfusion was followed after a short interval by a gradual and lasting improvement in the blood state, the first evidence of returning functional activity being a remarkable increase in the white corpuscle count from 3200 to 12,300, this leucocytic phase definitely preceding the period of red cell reconstruction. The patient was evacuated by hospital ship three months after his first transfusion. A full account of this interesting case will be duly published by Major Sturrock, who has kindly supplied me with the above details.

Treatment.

I do not propose to spend time in describing the routine measures of treatment which came to be adopted as the result of our experience of malaria in Macedonia. I have dealt with these in some detail in a recent article in THE LANCET (Jan. 24th, 1920), and will here limit my remarks to the discussion of certain points of general interest.

In endeavouring to estimate the value of quinine in the treatment of malaria one is at once impressed by the remarkable contrast between its controlling influence over the acuter manifestations and its comparative failure to prevent relapses in the more chronic forms. In acute malaria the results obtained by quinine properly administered and in sufficient quantities are little short of marvellous. As our experience grew the tendency was to give increasingly large doses in primary attacks, as it was found that this was the only stage of the disease at which permanent results in the sense of preventing relapses could be hoped for. In cerebral malaria the prompt use of intravenous quinine undoubtedly saved many lives. But as a means of controlling the incidence of relapses in recurrent malaria the efficiency of quinine was found to be on a very different plane. Numerous observations were made, some on a considerable scale, having for their object the comparison of large bodies of men; others in special malaria wards, where, with comparatively small numbers to deal with, it was possible to carry out a systematic comparison of various methods on a scientific basis. The practical outcome of an immense amount of work was the realisation of the impossibility of eradicating the malarial parasite from the system in cases of relapsing malaria by any method of treatment. While quinine was being taken in effective doses the disease was kept more or less under control, but on the cessation of treatment relapses again made their appearance, and after a few weeks became as frequent as in the period before the treatment was begun. The best results in relapse-control were obtained

¹ Lieutenant-Colonel A. W. Falconer, R.A.M.C., in an article on The Pulmonary Manifestations of Malaria, in the Journal of the Royal Army Medical Corps, February, 1920, describes a group of cases presenting the physical signs of more or less extensive consolidation of one or more lobes. He considers that in most of these cases the physical signs depend on massive collapse and not on true consolidation, and regards the condition as representing a pure malarial phenomenon. I was unfortunate in seeing very few cases in which the physical signs could be interpreted as due to pulmonary collapse, and formed the opinion that the most common pulmonary complication of malaria was a fine-tube bronchitis, with patchy consolidation of one or both lungs, probably due in all cases to a superadded infection.

in the special observation wards, under the direction of Major A. G. Anderson, R.A.M.C., by the "week-end" system of 30 gr. of quinine on each of two successive days in each week; an important advantage of the method is that treatment can be continued for an indefinite period. Under this system the percentage of non-relapsing cases was raised to 78, as compared with 32 per cent. in cases in which no quinine was given except for the treatment of relapses as they occurred. But for all its limitations no drug was found to exceed, or even to approach, quinine in efficiency. At one time with the introduction of galyl it was hoped that a parasite destroyer of considerable power had been discovered, but the promise of early trials was not fulfilled, and although the preparation undoubtedly possesses some parasite-destroying properties, specially in subtertian cases in which quinine has been pushed to the limits of tolerance, its chief value was found to lie in stimulating the blood-forming organs in cases of profound cachexia and in the anaemia of blackwater fever.

Methods of Administration of Quinine.

On the much-debated subject of the channel by which quinine may with the greatest advantage be introduced, a very decided impression was formed that a given quantity of quinine is more effective if injected intramuscularly than if taken by the mouth. It is difficult to say how far this impression was correct; observations made in the Special Malaria Laboratory on the rapidity with which parasites disappear from the blood and the rate of quinine excretion suggests that the advantage lies with oral quinine. Personally I hold the view that if the desired effect can be obtained by oral quinine there is no justification in submitting the patient to the inconvenience of intramuscular injections. But instances in which quinine requirements could not be met by the oral method were very numerous, and the value of the alternative channel was amply proved in such conditions as vomiting or intestinal disturbance, when absorption from the alimentary tract is impaired, and in cases of pernicious type, where it is imperative to produce a greater effect than can be obtained by mouth administration only, and in cases of cerebral malaria as a supplementary measure to intravenous injections. The risk of local complications is practically negligible if ordinary precautions are taken to prevent such mishaps as sepsis and injury to nerve-trunks. In a recent number of the *Journal of Hygiene* (October, 1919), Colonel L. S. Dudgeon has drawn attention to the serious degree of necrosis which follows intramuscular injections of quinine in mules and rabbits, and has suggested that medical officers and officers in charge of divisions in the Salonika hospitals were not fully alive to the injuries they might inflict on their patients. It may be said that, apart from cases of faulty technique, and a few instances of extensive necrosis that followed intramuscular injections in patients who were debilitated from the effects of dysentery, such untoward results were practically unknown in our clinical experience. The number of injections given was enormous, and there is no means of accurately estimating them; but assuming that each of 12 medical officers in each general hospital had occasion to give one intramuscular injection on each day during the malarial season of, say, 100 days—an assumption which is undoubtedly considerably below the mark—the total number of injections for the season would amount to 18,000, and yet with the exceptions mentioned above, it was the rarest event for any ill-effect to follow beyond a localised induration which rapidly subsided, leaving no permanent disability.

The treatment of malaria in patients who at the same time were suffering from dysentery presented special difficulties, as on the one hand oral quinine was badly absorbed and often of little use, and on the other hand there was the risk of intramuscular injections, if repeated, leading to serious damage to the muscle. With this combination of diseases it was often impossible to push quinine to the same extent as in a case of uncomplicated malaria. Many of the acute Shiga cases showed a marked febrile reaction, and in order to assess the pyrexia at its true value, the examination of blood films was found to be quite as important, if not more so, in the dysentery hospitals as in any other.

Symptoms Resulting from Administration of Large Doses of Quinine.

Of unfavourable symptoms as the result of the large doses of quinine which it was often necessary to give we had fortunately small experience. A few cases of idiosyncrasy were seen in which a moderate or even a small dose of quinine consistently gave rise to hæmoglobinuria. An instance of this was met with in a Greek boy, who had had malaria and was given a dose of quinine, with resulting hæmoglobinuria and the rapid development of a very marked anaemia. It was thought the matter might be a coincidence, and as there were special reasons for quinine treatment a further dose of 10 gr. was given after a short interval with the same dramatic result of an intense hæmolytic and severe anaemia. This condition should be sharply differentiated

from blackwater fever, which I believe comes and goes quite independently of quinine. A variety of skin lesions, such as erythema, scarlatiniform rashes, urticaria, and less commonly purpura occurred in definite association with quinine treatment. More serious than these was a condition of exfoliative dermatitis, of which I saw two examples. In each there was a protracted illness, in the course of which the exfoliative condition became generalised, and ultimately septic infection occurred, notwithstanding the most careful nursing, and the patient succumbed. The total duration of illness in one of these cases was six months.

In the course of 1917 12 cases of quinine amblyopia were reported. Further cases occurred in 1918, but I do not know the exact numbers; they were fewer than in the previous years. Of the 1917 cases, two followed the taking by mistake of a large but unknown quantity of quinine; in one two "mouthfuls," in the other four to six tablespoonfuls of quinine in solution were taken. The remainder were cases of severe malaria in which the need for pushing quinine in large doses was imperative. Most of these were cases of subtertian infection; in three the clinical condition was complicated by blackwater fever.

One patient, an officer, while on 30 gr. daily, developed cerebral symptoms and was given while unconscious 70 gr. of quinine intravenously and 90 gr. intramuscularly, 160 gr. in all. On regaining consciousness he was amblyopic. There was a gradual but slow return of vision, and when evacuated by hospital ship several weeks later there was still a considerable degree of amblyopia. Another case, of M.T. malaria with multiple rings, was given on Oct. 14th 30 gr. of quinine intramuscularly; on Oct. 15th 60 gr., half intramuscularly, half by mouth; and on Oct. 16th 60 gr. intramuscularly. After the evening dose he could hardly see, but the pupils reacted well to light. At 8 A.M. on Oct. 17th he was totally blind with widely dilated pupils which did not react to light. In the evening he could see a little. On Oct. 18th he was delirious, but apparently could see. On the next day his malarial symptoms were so urgent that it was decided after careful consideration to give more quinine, and 15 gr. were administered intramuscularly. After the injection there was rapid dilatation of the pupils and he became totally blind with pallor of the discs and contraction of the retinal arteries to a mere thread. On the following day he was given galyl, but in the evening the general condition was so grave that it was decided that further quinine treatment was imperative, since it afforded the only hope of saving his life, and that it must be undertaken even at the risk of permanent damage to the sight. Further doses of intravenous quinine were given, but the treatment was unavailing and the patient died.

In a third case of cerebral malaria 55 gr. of quinine were given on Nov. 21st, 60 gr. on the 22nd, and 20 gr. on the 23rd. He then became completely blind, and when I saw him a few hours later the pupils were widely dilated, failed to react, and the fundus was pale with very small thread-like arteries. No further quinine was given after the onset of blindness, but notwithstanding this there was not the slightest recovery of vision, and the patient was evacuated by hospital ship several weeks later, still blind. In this case continuous sluggish movements of the iris were observed independently of light stimulus.

These cases fall into three groups: (1) Those in which there is fleeting amblyopia followed by full recovery of vision; (2) cases of incomplete recovery in which useful vision is restored but with a varying degree of lasting contraction of the fields; (3) a comparatively small group in which blindness is permanent.

The Y Scheme.

Owing to increased submarine activity in the first half of 1917, facilities for invaliding by sea became greatly restricted, and there ensued a gradual accumulation in the Salonika command of men whose usefulness for military purposes was practically nil, since by reason of repeated attacks of malaria they spent the greater part of their time at hospitals and convalescent depôts, in many cases being readmitted from C.D. to hospital for a malaria relapse before their period of convalescence was completed. These men were not only unfitted for active service and an unnecessary burden on the military machine, but as possible carriers they constituted an actual danger to the community. On the other hand, there was a fair prospect that under less trying climatic conditions a proportion of them would recover to a sufficient extent to be of use in the home command or in France. These circumstances led to the inception and organisation of the Y scheme, and by the latter part of December, 1917, the necessary arrangements had been completed and the first drafts were evacuated from Salonika under the scheme. The men were chosen with the greatest care, every case being inspected either by the D.M.S. or the consulting physician before being passed as suitable for evacuation. The scheme worked well, and by Oct. 31st, 1918, a total number of 26,001 officers and other ranks had been evacuated, to the great advantage both of the command as a whole and of the men themselves. I am told that these officers and men, not only useless but a danger to their companions in the East, have in a large proportion of cases regained their health and strength, and have been responsible for much good work both at home and on the Western front.

Malaria in the Caucasus.

The shifting of the troops after the armistice from Salonika to the neighbourhood of Constantinople and to

the Caucasus was followed by a marked improvement in the health of the army, and at the same time there was a considerable change in the character of the sickness. The dominance of malaria over all other conditions dwindled, and diseases, such as typhus, small-pox, and relapsing fever, of which only occasional isolated cases cropped up in Salonika, made their appearance in increasing numbers during the early spring of 1919. Thanks to protective measures and early isolation of cases, these diseases were always under control, and did not assume anything approaching the dimensions of the epidemics by which large sections of the Turkish and Russian armies were devastated. The approach of the malarial season was awaited with some curiosity, as we were anxious to see how far the prediction of a heavy malarial incidence in this new country would be fulfilled. In June, when I had an opportunity of visiting the medical units in the Caucasus, except for recurrent cases carried over from previous seasons, there was no malaria. My first note of primary malaria was on July 14th, when a man from Batoum, who came out from home in December, 1918, was admitted to a general hospital in Constantinople with a B.T. infection. There may have been a few isolated cases before this, but, in contrast to our experience in Salonika, primary malaria in the early summer in the Caucasus was a negligible quantity. On a subsequent visit in the latter part of August the state of things was very different, and there were serious outbreaks of malaria in many parts of the country. At an aviation post at Petrovsk, on the shores of the Caspian, 50 out of 150 men had gone down in the course of a fortnight. A battalion on its way to Shusha, a post among the hills, had its orders changed while en route, and encamped at Barda on the plain, on a site chosen, among other reasons, for its propinquity to a stream. I was told by the C.O. that no mosquitoes were noticed until about 10 days later, when men began to go down with malaria. I visited the battalion a few weeks later after they had moved to a healthy camp on high ground above Tiflis, and by that time out of a total of 305 N.C.O.'s and men 303 had fallen victims to malaria. A large proportion had been sent into hospital, but fresh relapses were occurring every day, and it was with great difficulty that fatigue parties could be mustered for the performance of the ordinary camp duties. At this period there was a general movement of troops in progress from Baku and Tiflis to the Black Sea coast at Batoum, where malaria was also prevalent, most of the available camping-ground being heavily infested by anopheline mosquitoes.

BLACKWATER FEVER.

During the year ending Oct. 31st, 1918, 136 cases of blackwater fever were reported in the Salonika command, of which

36 died, giving a case-mortality of 26.5 per cent. In the previous year only 18 cases were reported. The circumstances of the two years are not strictly comparable, as in the course of 1916 malaria cases in large numbers were being invalided to Malta, and during the following winter blackwater fever was common in Malta. Owing to submarine risks and consequent restrictions in sea-communication between Salonika and Malta

FIG. 2.—Blackwater fever.—Number of cases reported monthly during the year ending Oct. 31st, 1918. The heavy lines represent the months as given above.

the evacuation of malaria cases on a large scale became for the time impossible, and the accumulation of these cases in Salonika was doubtless largely responsible for the rise in the blackwater figures. The chart (Fig. 2) shows the seasonal incidence of the disease; it is seen that the great majority of cases occurred between December and April, with a maximum in February, and that during the summer there were no cases except for a short outbreak during September. This happened to correspond with the military advance, and is probably related to the strenuous conditions and special hardships of that time. During the winter there were three short spells of exceptionally

severe weather. The first of these was in early December, and coincided with the beginning of the blackwater season; the second was in early January; and the third, at the end of March, may have been responsible for checking the fall in the number of blackwater cases that had already taken place. There was no specially severe weather in the last three weeks of January or during February, when blackwater fever attained its maximum incidence.

The Relation of Blackwater Fever to Malaria.

The outstanding feature in the ætiology of blackwater fever is its relation to malaria. Of a series of 78 cases which I had special opportunities of investigating, in all except one a definite history of malaria was obtained, and seeing how prevalent malaria was it is more than probable that this single case was really no exception to the rule that malaria is an invariable antecedent of the condition. But notwithstanding this general relationship, it was rare to find evidence of more than slight malarial activity during the actual blackwater attack. In only 27 per cent. of a series of 58 cases in which special care was given to the examination of the blood were there positive findings, and in nearly all of these the number of parasites present was very small. The type of parasite was B.T. in seven cases, M.T. in four, and indeterminate forms, probably M.T., in five cases. That some agent other than the malarial parasite is the determining factor in the acute hæmolytic of blackwater fever is further suggested by its seasonal incidence, which in Macedonia is at its height not during the malaria season, but at a time of year when malarial activity is at its lowest level. What the determining factor is remains at present obscure. No support was found for the hypothesis that quinine is the activating agent. On the one hand, blackwater occurred in cases in which no quinine had been taken for a considerable period; on the other hand, in several cases quinine was given in large doses without prolonging the period of blackwater; it was the practice of some M.O.'s, in the belief that blackwater fever was the expression of a specially malignant type of malaria, to treat the condition energetically with quinine, and I have many charts which illustrate the rapid and complete clearing of the urine under these conditions.

Clinically the cases presented no special features. The abrupt destruction of enormous numbers of red corpuscles, leading to a drop to 30 per cent., or even 20 per cent., of the normal number; the state of collapse with extreme pallor and small compressible pulse; the rapid darkening of the urine with characteristic absorption bands; the pyrexia with shivering, vomiting, headache, and lumbar pains all went to form a picture which differed in no essential from that described in connexion with outbreaks elsewhere. The average duration of hæmoglobinuria was three days; the longest period was five days; in one case characteristic dark red urine was passed on a single occasion only; all subsequent specimens were clear. Two symptoms we learned to regard as of specially grave significance—jaundice and suppression of urine. Enlargement and tenderness of the liver, with slight icteric staining of the skin, was a common feature of nearly all cases; but deep jaundice was a symptom only of the more serious cases and was nearly always followed by death; in every one of 30 fatal cases there was well-marked jaundice; in 17 of these the icteric staining was intense. In all the fatal cases except two there was either complete suppression of urine or the amount was reduced to a few ounces per diem. In the two exceptions a fair secretion of urine was maintained to the end; in both of these cardiac dilatation with pale and flabby muscle was found post mortem. Suppression was often associated with persistent vomiting and intractable hiccough, causing great distress to the patient and rapidly leading to exhaustion. In some cases hypodermic injections of hyoscine (1/100 gr.) combined with morphia (1/6 gr.) were successful in controlling these symptoms when other means had failed.

Treatment.

The most important measures in treatment were found to be warmth and the introduction of large volumes of fluid either by mouth, rectum, subcutaneously, or in exceptional cases intravenously with the object of diluting toxins and maintaining a free flow through the kidneys. The use of Souttar's apparatus was of great value, as by this means continuous rectal administration of saline can be effected, and as much as 5 or 6 pints introduced in the course of 24 hours. The life of one patient, a nurse, under the care of Major Anderson, was undoubtedly saved this way. The general rule in regard to quinine was to withhold it unless there was

evidence of concurrent active malaria. If parasites were present, or the spleen was enlarged and at the same time tender, quinine was given in full doses and with beneficial results.

DYSENTERY.

Next in numerical frequency to malaria, and hardly less important in its consequences, was dysentery. The total number of admissions for the three years was 21,147, representing a ratio per 1000 troops of 64 in 1916, 29 in 1917, and 58 in 1918. The total number of deaths was 414, equivalent to 1.9 per cent. of admissions; or calculated as a ratio per 1000 troops, 1.4 in 1916, 0.6 in 1917, and 0.98 in 1918. The above figures are probably in excess of the actual numbers, especially for the year 1918, as, owing to the importance of early treatment and the impossibility of bacteriological examination in all cases, it was agreed to accept as the basis of diagnosis clinical criteria irrespective of bacteriological proof. This policy was deliberately adopted as affording the maximum of protection to the community, though it doubtless involved a diagnosis of dysentery in a certain number of cases of acute enteritis which were really due to some other cause.

There are, unfortunately, no figures available to show the relative frequency of the amoebic and bacillary forms of the disease. The latter was the dominant form, and though amoebic cases were present throughout, it was only late in the season of 1917 that the extent to which this form prevailed in the command came to be recognised, partly owing to the indefatigable work of a protozoologist who spent his whole time in visiting laboratories, giving his opinion on doubtful specimens, and advising as to methods. Evidence gradually accumulated of the existence of a widespread amoebic infection in its most insidious form, being carried by apparently healthy individuals, with or without a history of previous dysentery, and often suffering from no disability beyond occasional attacks of diarrhoea. The policy with regard to evacuation of dysentery cases became more and more stringent; first all proved cyst carriers were sent home; then all cases who came under observation with a history of repeated attacks of diarrhoea; then all dysentery cases with a history of a previous attack; and, finally (in 1919) all cases of dysentery, amoebic or bacillary, first attacks or otherwise, clinical or bacteriologically proved, were evacuated by hospital ship. These successive measures indicate the importance which came to be attached to the rôle played by carriers in spreading the disease in both amoebic and bacillary forms. It is impossible to say how far these measures might have succeeded in reducing the disease had troops remained in Salonika during 1919 in the same numbers and under similar conditions; with the rapid evacuation of troops after the armistice and the shifting of headquarters to Constantinople the conditions were radically changed; but it is worth noting that the type of dysentery seen in the hospitals in the Caucasus during 1919 was very different from that we had been familiar with in Salonika; the bulk of the cases were mild and of short duration; serious cases were uncommon, and the death-rate for the year was only 0.43 per 1000 troops.

Of equal importance to human carriers, and commonly forming an intermediate link in the chain of infection, came flies. The plague of flies was at its worst at two periods of the year, in the early summer and in the autumn; at both these seasons the heat was accompanied by a relatively high humidity; during the intervening months of great heat with dryness the fly nuisance was largely mitigated. Turning to the dysentery curve, it is seen to present a precisely similar seasonal variation, with an initial outbreak in the spring, reaching its maximum in late June and July, followed by a substantial reduction in the number of cases during August and September, and a recrudescence of disease in the autumn, at its height at the end of October or early in November. (Fig. 3.) This coincidence, obvious on the larger scale, was worked out on a more exact basis for a group of hospitals near Salonika, by Captain J. F. Taylor, R.A.M.C., whose observations go far to incriminate the fly as a carrier of dysentery organisms. Not only did he establish the fact that in

these hospitals the incidence of dysentery corresponded exactly to the prevalence of flies as measured by the numbers caught in traps, which were exposed from 11 A.M. to 2 P.M. on each day, but he also showed

FIG. 3.—Dysentery.—Weekly admissions during 1918 shown as ratio per 1000 of strength.

experimentally that the fly is capable of carrying both Flexner and Shiga bacilli; in one instance he recovered from a fly, captured in a hospital kitchen, Shiga bacilli with typical cultural and agglutination characters.

Clinical Features.

As with malaria, so in dysentery, a few cases were seen in which the initial symptoms appeared with such dramatic suddenness, and the intestinal disturbance was of so severe a character, that the possibility of the case being one of cholera could not be dismissed without serious consideration. The possibility of an outbreak of this disease had always to be reckoned with, though fortunately the organisation which had been prepared to meet such a contingency never had to be put to the test. In the cases referred to all the initial symptoms of cholera were present—copious rice-water stools, profuse vomiting of watery fluid, cramps, low blood pressure, and rapid collapse; but an immediate examination of the stools showed an absence of vibrios, and the cases, which ultimately were proved to be dysentery, responded rapidly to intravenous injections of antidysenteric serum combined with hypertonic saline.

Edema.

Another interesting group of cases was characterised by oedema. This sometimes developed during the acute phase of cases of a severe Shiga infection, in which there appeared to be a rapid flooding of the system with dysentery toxins. In other cases the symptoms appeared at a later stage and in the absence of any of the usual antecedents of oedema. The cardiac condition, though feeble, was not in itself sufficient to cause oedema; the urine was not reduced in quantity, and though containing albumin in varying amounts, it had none of the characters which are usually associated with acute nephritis. The possibility of the condition being due to a food deficiency, and connected with the drastic restrictions in diet which were found essential in the routine treatment of acute dysentery, deserves consideration. A noteworthy feature is that ascites was often a prominent symptom, and out of proportion to the oedema elsewhere; thus in one case ten pints of fluid were removed from the abdomen, and on the following day, when I saw the patient, there was still a large amount of fluid present.

Other cases of special interest were those in which after the cessation of all intestinal symptoms pyrexia continued and the patient rapidly lost ground and became emaciated. The tongue was usually dry, smooth, and shiny. A liberal diet made little or no difference to these patients. They were able to take and digest a considerable amount of semi-solid food without diarrhoea or any symptoms of gastric or intestinal disturbance, but their assimilative powers seemed at fault and they steadily lost weight.

Hæmorrhage and Perforation.

These were both very rare complications. The first event was more common in connexion with the ulceration of long-standing amoebic dysentery than in cases of bacillary origin. In cases of perforation the actual rupture of intestine was almost always preceded by an adhesive peritonitis, which sufficed to prevent a general infection of the peritoneum. The resulting abscess formed slowly and was strictly localised. The whole process was very insidious, and, being marked by no special symptoms either at the time of perforation or during the subsequent stage of pus formation, might easily be overlooked. In one instance of acute Shiga dysentery a generalised acute peritonitis occurred without perforation; except for rather marked meteorism, the features of the case were in no way distinctive, but at the

post-mortem examination general peritonitis was found, with two pints of thin purulent fluid in the abdomen. The intestines were examined with the greatest care, but no perforation was discovered.

Arthritis.

Although arthritis cannot be called a common complication of dysentery, there were during the season always a few cases under treatment, arising more often in complication of Shiga than of Flexner infection. The condition usually appeared in the course of the third week and involved one or more of the larger joints, especially the knee. In the acute stage there was considerable enlargement and tenderness of the joints, with effusion of fluid, and pyrexia of irregular type. The acute stage was followed by a protracted period, during which the fluid was absorbed and some thickening of the periarticular structures took place, giving rise to a condition not unlike that of rheumatoid arthritis, with considerable stiffness and pain on movement. In some cases the course was so prolonged that a permanent disability seemed inevitable, but I remember no case, however protracted, which had not made some progress towards recovery before leaving hospital. In the acute stage rest is necessary, and when the joint was tense with fluid much relief was afforded by tapping and the removal of the fluid. In a few cases treated with antidyenteric serum there was a rapid fall of temperature, with subsidence of joint symptoms. This method of treatment merits further trial, though it should be used with caution in cases that have previously been given serum during the stage of acute dysentery on account of the risk of anaphylaxis. After the acute symptoms have subsided it is a mistake to keep the joint absolutely at rest; massage and carefully regulated passive movements should be employed, and radiant heat is useful. The joint fluid is generally turbid, and in one case of a series of ten examined bacteriologically by Captain R. R. Elworthy, R.A.M.C., a Shiga bacillus was isolated from the fluid and cultivated. In the remainder of the series the fluid was sterile. Dysenteric arthritis is readily distinguished from serum arthritis by the lateness of its onset (usually between the fourteenth and twenty-third days of the disease) and by the comparative severity and long duration of the lesions. An interesting point is the almost constant association with conjunctivitis, which was a useful herald of the advent of arthritis, since it appeared usually about 48 hours, but sometimes several days, in advance of the joint condition.

Nervous Complications.

These were observed in sequel to both amoebic and bacillary forms of dysentery. A man who had just completed a second course of emetine treatment for an attack of amoebic dysentery after three months from the onset of his symptoms developed paresis of the legs. On the next day (July 14th) the knee-jerks, which had been present on the 13th, were unobtainable, and there was weakness of the grasp on both sides. On the 15th there was difficulty in swallowing, breathing was laboured, and the voice was hoarse. Two days later (July 17th) there was complete loss of power in the legs, which were flaccid. Sensation was unimpaired. On the 18th there was anaesthesia on the inner aspect of both legs and knees, there was very little power in the recti muscles, respiration was chiefly intercostal, and the patient was unable to puff out his cheeks. The cerebro-spinal fluid was under slight pressure; its characters were normal. On the 21st there was incontinence of urine and faeces. In the course of the following days breathing became very difficult, the patient was irritable and restless, and on the 25th he died, 12 days after the onset of nervous symptoms. Post mortem the meninges of the brain were congested and the cerebro-spinal fluid was in excess, otherwise there were no macroscopical lesions of the nervous system. The intestines showed evidence of long-standing dysenteric ulceration. Unfortunately no data as to the microscopical lesions were forthcoming. In another case of clinical dysentery, not bacteriologically proved, paresis of both legs and both arms, with loss of deep reflexes, supervened a fortnight after the cessation of intestinal symptoms. The cardiac dullness was increased both to the left and to the right, the breathing became embarrassed, and the patient died of heart failure 19 days after the onset of paresis. Post mortem all the chambers of the heart were dilated, the brain and meninges were congested and oedematous, and marked degenerative changes were found in sections of the popliteal and vagus nerves that had been removed for examination.

Amoebic Hepatitis.

This subject is one that would be more fittingly dealt with by one of my surgical colleagues. Some scope, however, was provided for the exercise of the physician's art, both in diagnosis and treatment, as the diagnosis largely depended on the correct reading of the physical signs produced by an upward displacement of the diaphragm, usually on the right side, with shifting of the heart to the left and collapse of the

lower portion of the right lung; also, by prompt emetine treatment the process was often arrested in the pre-suppurative stage.

Brief particulars may be given of two cases with unusual features, the records of which were kindly supplied to me by Major St. J. D. Buxton, R.A.M.C. The first case was of interest owing to the occurrence of general peritonitis, which supervened without obvious cause four weeks before pus was located in the liver and cleared up satisfactorily after operation and the removal of seropurulent fluid from the abdomen. Subsequently a right-sided pleurisy occurred with clear effusion, which became converted into an empyema owing to sloughing of the diaphragm and escape of the contents of the liver abscess into the pleural cavity, as was shown later at the operation. This patient made a good recovery. The second case, a fatal one, was remarkable for the presence of two large abscesses in the right lobe and numerous small abscesses about the size of a pea in both right and left lobes of the liver; one of the two larger abscesses was incised and drained, but was found at the autopsy to have leaked downwards below the colon and caecum. In view of the multiple foci of suppuration it is clear that no further operative measures could have saved the life of this patient. The association of a clear pleural effusion with pus in the liver was observed in another case, the nature of which was obscure until in the course of the fifth week a large aspirating needle was introduced into the right pulmonary base and six ounces of very thick pus were withdrawn. In the course of operation on the following day clear fluid, through which the aspirating needle must have passed, was found in the pleural cavity; below this was a liver abscess, which was incised and drained.

In the dysenteric wards there were always to be seen the best instances of combined infections, with a complex clinical picture, in which it was often difficult to assess the relative importance of the various infective agents. The case may be quoted of a patient admitted to hospital with a proved Flexner infection. As the result of pathological observations initiated on the following day subtertian parasites were found in the blood, *Entamoeba histolytica* in the stool, from which Shiga bacilli were also isolated. Three days later he fell a victim to influenza; bronchiolitis supervened and he succumbed. Total, five distinct infections.

Treatment.

Among the many points of interest which might be discussed in connexion with the treatment of dysentery I will make no reference to the important subjects of dieting and the use of salines and will confine my remarks to two points only: (1) the use of serum in bacillary dysentery, and (2) the value of emetine in amoebic cases.

As regards serum treatment we were at a disadvantage in being supplied with a polyvalent serum of whose specific properties we knew very little beyond the fact that in different samples agglutinins against the various types of dysenteric organisms were represented in very varying degrees. The situation was to some extent cleared in 1913 by Colonel Dudgeon, who by his observations on 17 samples of sera showed that many of them were very deficient in agglutinins, especially for *B. Shiga*, which were precisely the ones for which we had the greatest need, as the Shiga bacillus was undoubtedly the organism responsible for the bulk of the more serious cases of acute dysentery. If it had been practicable to supply us with pure anti-Shiga and anti-Flexner sera more striking results would doubtless have been obtained. Even as it was, working with sera of undefined therapeutic properties, a favourable impression on the whole was formed of the value of serum treatment, given two conditions—(1) that the serum was administered at the earliest possible moment, and (2) that sufficiently large doses were used. The tendency with serum in dysentery, as with quinine in malaria, was to give increasingly large doses as our experience grew, and latterly amounts of 80 to 100 c.cm. were given subcutaneously in all cases with the clinical features of an acute bacillary dysentery immediately on admission, without waiting for a bacteriological report. The dose was usually repeated on the following day, and again on each of the succeeding two or three days, in the same or reduced amount, according to the course taken by the disease. In cases of special severity serum was given intravenously in combination, if necessary, with normal saline or isotonic glucose solution. The value of intravenous saline was very great in dehydration cases with copious watery stools, a condition in which the maintenance of the body fluids is of the utmost importance. The prospective benefit of serum treatment in any given case rapidly lessens with the lapse of time from the onset of symptoms, and the opinion was formed that nothing is to be gained by the inauguration of serum treatment later than the sixth or seventh day of the disease. Serum rashes and transient joint symptoms were not uncommon; these were sometimes accompanied by severe febrile reaction; true

anaphylaxis was, fortunately, very rare. A valuable article on the diagnosis and treatment of dysentery in the British Salonika Force was read by Lieutenant-Colonel Duncan Graham, C.A.M.C., at a meeting of the Salonika Medical Society in May, 1917, and published later in THE LANCET of Jan. 12th, 1918. In the light of subsequent experience it is interesting to note his opinion, expressed at that time, that less than 3 per cent. of the dysentery in the Salonika area was of the amoebic type.

In the treatment of amoebic cases emetine was of the greatest value in controlling acute symptoms and causing the disappearance, at least for a time, of cysts and amoebae from the stools. But in a large proportion of cases the benefit was temporary, and periodical examination of the stools sooner or later disclosed the reappearance of organisms, though the accompanying intestinal disturbance might be of very slight severity, amounting only to looseness of the bowels, with or without the presence of mucus in the stools. From figures supplied to me by Captain C. W. Budden, R.A.M.C., who was in charge of the special section at the convalescent depot to which dysentery cases were discharged, it appeared that of all dysentery relapses, 65 per cent. were in amoebic cases, and that of all amoebic cases which came under his care 75 per cent. never became sufficiently fit to return to duty. It cannot be said that these patients had not received adequate emetine treatment; in every refractory case at least two, and sometimes more than two, full courses of emetine were given, though it was eventually realised that if a patient was not cured by a second course it was waste of time to give further treatment in Salonika, and that the only prudent course was to evacuate him from the command as soon as possible. The value of emetine in acute dysentery was very similar to that of quinine in malaria—that is to say, of the greatest use in controlling the acute manifestations of the infection, but disappointing when used for the purpose of eradicating the parasites from the system. A course of emetine lasted for 12 days, during which the patient either received $\frac{3}{4}$ gr. hypodermically twice daily, or 1 gr. hypodermically, plus $\frac{1}{2}$ gr. by the mouth daily, or 3 gr. of bismuth-emetine-iodide by mouth, either alone or in combination with hypodermic treatment. From statistics in No. 15 of the Special Report Series of the Medical Research Committee it appears that emetine treatment meets with a greater measure of success here in England than was the case with us. This is no more than one would expect, and justifies our policy of the early evacuation of cases which did not rapidly clear up.

The criterion adopted for the discharge of bacillary cases from both hospitals and convalescent depôts was a purely clinical one; after a week on full diet and in the absence of intestinal symptoms the patient was regarded as fit to leave hospital, and similarly if there was no recurrence of symptoms during his stay at the convalescent depot, and his general health was good, at the end of three weeks he was passed as fit for duty without bacteriological examination. Special importance was attached to the presence of mucus in the stools as evidence that the dysenteric process had not completely subsided.

ENTERIC GROUP.

Of the enteric group I have very little to say. The troops were well protected and the incidence was small. Fig. 4 shows the incidence of all forms grouped together

FIG. 4.—Enteric group.—Showing incidence of all forms as a ratio per 1000 troops.

for the three years 1916-18. It is seen that there is a marked drop from 11.77 per 1000 troops in 1916 to 0.84 per 1000 in 1918. In Fig. 5 is shown an analysis into the various members of the group for each of the three years. I cannot explain the large number

diagnosed as "enterica, clinical" during 1916; it is out of proportion not only to the pathologically proved cases in the same year, but also to the number of "clinical cases" in the following years. Of cases pathologically proved it is seen that most were paratyphoid, para. A being in excess of para. B, specially in the two later years. The disease with few exceptions was of a mild type, and only 65 deaths occurred during the whole period. The case-mortality in 1916 was 3.62 per cent.; in 1917, 3.78 per cent.; and in 1918, 4.44 per cent. The majority of severe cases were due to *B. typhosus*, a large proportion of these being admitted to hospital from vessels arriving at the port.

INFLUENZA.

The outbreak of influenza with its attendant complications took a heavy toll of the forces, and was the cause of special anxiety owing to the fact that the height of the epidemic corresponded to the military operations in September, 1918, which led to the defeat of the Bulgars and the signing of the armistice with Bulgaria. The total admissions for influenza and pneumonia during 1918 were 17,813, being at the rate of 111.33 per 1000 troops, and the total number of deaths was 1387, or 8.67 per 1000; that is to say, almost 1 man out of every 100 troops fell a victim to the disease. The mortality was greatest during the five and a half weeks from Sept. 22nd to Oct. 30th, when deaths were occurring at the rate of 112 per week.

The epidemic first made its appearance in June in an outlying prisoner-of-war camp near Ekaterini, where there was an extensive outbreak of more than 800 cases, nearly all of mild type. By the end of June cases of what had come to be described as the "prevailing epidemic," many of them with serious pulmonary symptoms, were common in the Janes district, and as at the same time and in the same area there was an outbreak of sandfly fever, and every day showed a rising rate of admissions for malaria, the differentiation of these diseases was often difficult, and a certain degree of confusion in diagnosis was inevitable. At the end of August there was a serious outbreak of disease among Indian troops and Turkish prisoners of war at two adjacent camps at Arakli Farm, near Llangaza Lake; some of these were cases of malaria, but in the majority the illness differed from malaria in the sudden onset without rigor or shivering, the absence of enlarged spleen or splenic tenderness, and the presence of a respiratory tract catarrh. Of the malaria cases in this outbreak there was a great preponderance of M.T. infection, as proved by examination of blood films. Another serious outbreak occurred a week or two later in a battalion 590 strong on the Doiran front; of these, 130 fell ill, chiefly from two companies, in the course of three days; the infection spread

rapidly, and in a couple of weeks the whole battalion was, in the words of the medical officer, "almost burnt out." In the earlier stage of the influenza epidemic attempts were made by segregation of the sick to prevent its spread, but these proved unavailing, and the disease rapidly became practically general through the command.

Clinical Features.

The clinical features of the epidemic in Macedonia do not appear to be essentially different from those of the epidemics at home and on the Western front, and I have little to add to the full and vivid account given by Major J. Burnford, R.A.M.C., in a

communication to the Medical Section of this Society on April 29th, 1919.

The disease usually began as an intense tracheitis spreading to the bronchial tubes, and in the more severe cases rapidly involving the finest elements of the bronchial tree

FIG. 5.—Enteric group.—Showing relative incidence of different varieties. T., typhosus; A, para A; B, para B; C, clinical.

with a patchy consolidation of lobular type. A true lobar pneumonia was comparatively uncommon, but frequently so many lobules were involved that the condition became confluent and the physical signs were indistinguishable from those of a lobar consolidation. Pleurisy and empyema were common complications. Other grave complications were necrosis of the lung leading to multiple abscesses, pericarditis, and meningitis. In one case next to no normal lung tissue was left; the lower lobes, middle lobe, and central part of the upper lobes were in a state of necrotic disintegration, crumbling under the finger, and readily separated from the pleura and the connective framework of the lung. The remainder of the upper lobes was emphysematous, some of the bullae being of the size of a Tangerine orange.

The course of the disease was sometimes very rapid. In the case of a V.A.D. a state of generalised bronchiolitis was developed within a few hours, causing intense dyspnoea and cyanosis, with fine bubbling râles audible over the whole surface of the chest. Death took place within 24 hours of the onset. A common feature was the abundance of thick purulent sputum, sometimes streaked with bright red blood. This was difficult to expectorate, and its accumulation in the bronchial tubes led to marked dullness on percussion and complete abolition of breath sounds over the affected part. Voice vibration was diminished or absent, and in some cases these "silent" lungs could hardly be distinguished from pleural effusion except by the exploring needle. In some cases there was a rapid poisoning of the cardiac mechanism by toxins, and death was due to heart failure; in others there was prolonged resistance, the pulse remaining good till near the end, death apparently being due to the mechanical effects of a prolonged blocking of the bronchial tubes. Little could be done for the relief of this condition, which was most distressing, the patient literally fighting for breath and life over a period of many days. An interesting group of cases was that in which the temperature came down by lysis, and there ensued a long apyrexia period, during which the patient steadily lost ground and ultimately succumbed. In other cases sudden death occurred from cardiac failure after the fall of temperature and when the patient was apparently progressing towards a satisfactory convalescence. Cases were, unfortunately, common in which influenzal pneumonia was complicated by an acute attack of malaria, a combination which usually proved fatal.

I cannot leave this part of my subject without paying a tribute to the devotion and utter disregard of personal risk displayed by the nursing staff on duty in the wards reserved for serious cases during this epidemic. The work in these wards was extremely heavy, and the risk of catching a disease which might prove fatal was a very real one; but they did not spare themselves and the nursing of the sick throughout the emergency was worthy of the best traditions of the profession.

SANDFLY FEVER, &C.

Outbreaks of sandfly fever occurred at various places during the hot seasons, specially at Janes and at Chanak, and on more than one occasion the routine work of a medical unit was carried out only with great difficulty owing to the rapidity with which one member after another of the community fell a victim to the disease. Distinguishing points from malaria, apart from the blood examination, were the conjunctival injection with pain behind the eyes, the severe character of the pains in back and limbs, and the fact that with an equal degree of pyrexia the patient was not so much under the weight of his illness as during the actual attack of malaria. Initial rigors were rare, and the temperature curve, with its maximum on the first day and its gradual fall during the two following days, was unlike that of any type of malaria. The subjective feelings of the patient were different in the two diseases; a patient with sandfly fever who had had previous experience of malaria was always emphatic that his present illness was something different from malaria. The presence or absence of sandfly bites gave no help, as it was common during the sandfly season for patients with malaria to bear the marks of previous bites: on the other hand, sandfly fever might occur without any marks on the skin or any knowledge on the part of the patient that he had been bitten.

Sporadic cases of acute meningitis were seen from time to time, the majority being due to the meningococcus, while others were in connexion with the influenza epidemic. In one case of meningitis involving both brain and spinal cord films and cultures from the meninges showed a Gram-positive coccus; cultures from the heart's blood obtained post mortem also showed a Gram-positive coccus which was morphologically identical with *Staphylococcus aureus*.

In 1917 a neurological section was started at one of the general hospitals, in which invaluable work was done by Captain T. Graham Brown and Captain R. M. Stewart, R.A.M.C., who were in charge of the department. As I understand it is their intention to publish a full account of the work of the department, I will make no further reference to it here.

TREATMENT OF PRISONERS IN BULGARIAN HOSPITALS.

Shortly after the armistice I made two expeditions to Bulgaria, as far as Sophia, and from there to Pirot, just beyond the Serbian frontier. In the Bulgarian hospitals at Sophia there were a few of our men who had been taken prisoners of war and were being treated for wounds or sickness. None of them were seriously ill, and in conversation they all expressed themselves as satisfied with the way in which they were being looked after; they were evidently receiving the same attention as the Bulgarian patients, and so far as could be seen the Bulgarian doctors were well trained and skilful, though much handicapped through shortness of medical supplies and appliances. There was also great scarcity of provisions, and our men found it necessary to supplement their scanty rations by buying bread, as far as their resources permitted, at the exorbitant prices which were ruling in the town. One of the hospitals was equipped with a complete set of Zander apparatus, a gift from the German Red Cross at the beginning of the war; when the Bulgarian collapse was imminent and the Germans left Sophia they wanted to take this costly apparatus away with them, and had to be reminded by the Bulgars that it was a gift, not a loan.

Very different was the treatment of Serbian prisoners-of-war patients by the Bulgars. At Radomir, an hour's run from Sophia to the west, was a concentration camp for prisoners of war, and attached to this was a so-called hospital. The dysentery ward was crowded with patients lying on filthy mattresses on the floor, two or three to each mattress; these patients were mostly suffering from acute dysentery, and were supplied with no conveniences and no attention beyond what they could give one another. A Bulgar doctor was supposed to see them daily, but I was told that before the arrival of the British he seldom visited this ward and the only regular attention they received was a morning visit from orderlies to look round and remove the bodies of those who had died during the previous 24 hours. As I was leaving the ward one of the inmates in a far corner called out to me in English; he was one of our men who by some mischance had got mixed up with the Serbian patients; it was not many hours before he was being cared for in a section of a F.A. that had recently arrived at Radomir, to his unspeakable relief. He was suffering from a severe attack of dysentery, but when I last heard of him he was doing well. Thanks largely to the energy of Colonel J. Ward, D.S.O., backed by the Bulgarian D.M.S., who gave what help he could, hospitals for sick and wounded Serbs were rapidly organised and staffed by our R.A.M.C. at Sofia, Radomir, and later at Pirot, where Serbs once more after long disuse were able to enjoy the advantages of good treatment and careful nursing.

TYPHUS AND RELAPSING FEVER.

A few cases of typhus and relapsing fever occurred in the Macedonian area. Both these diseases became relatively more common after the movement of troops to Constantinople and the Caucasus, though there was never anything approaching an outbreak on a large scale. The Weil-Felix reaction was of value, specially in mild cases, though its usefulness was restricted owing to the fact that a positive result could not be expected earlier than the fifth day, by which time the diagnosis had in most cases become clear on other grounds.

From investigations made by Captain J. Warnock, R.A.M.C., it appeared that the rise in the agglutinating power of the serum was very rapid, and in the course of 24 hours there might be an increase from 1/25 or 1/50 to 1/100, which was taken as the standard for a positive result. This standard was reached on the fifth day, sometimes earlier, and was followed by a rapid rise in agglutinating power, until at the end of the pyrexial period (tenth to fourteenth day) a reaction was obtained with a very high dilution—e.g., 1 in 3000, 1 in 8000, and in one case 1 in 32,000. The subsidence of fever was followed by a rapid fall in the reaction. Control observations were made in cases of relapsing fever, cerebro-spinal fever, small-pox, typhoid fever, malaria, influenza,

pneumonia, syphilis, and in normal individuals with negative results.

As an example of the utility of the reaction a case may be quoted in which marked meningeal symptoms were present at the onset; as a result of lumbar puncture a few drops of semi-gelatinous mucoid material were obtained containing scanty lymphocytes and no micro-organisms; the Weil-Felix reaction was positive on the seventh day with a dilution of 1 in 100; on the tenth day it was marked at 1 in 1600, and slight at 1 in 3200.

In the state of profound toxæmia, which characterised the severer forms of typhus, benefit was derived from repeated intravenous salines. In the case of a patient at Tiflis who was desperately ill, in a semi-delirious state with low temperature and irregular pulse almost imperceptible at the wrist, and dry, thickly-coated tongue which could hardly be protruded, this procedure seemed to be the turning point of the illness, and when seen a week later he was convalescent. Among the complications and sequelæ of typhus observed in our own units and in Russian hospitals, I may mention suppurative parotitis, otitis media with mastoid disease, bronchitis and broncho-pneumonia, femoral thrombosis, and hemiplegia. In one case a complete unilateral paralysis of head, arm, and leg developed gradually in the course of three days during convalescence.

VISITS TO CIVILIAN AND MILITARY HOSPITALS IN RUSSIA.

While travelling in the Caucasus and Southern Russia in the summer of 1919 I had opportunities of visiting hospitals, both civilian and military, other than our British ones. At Batoum I visited the general hospital for the province and the infectious hospital for the town, both civilian hospitals, but under different management.

The first was fairly well run on very limited resources; they were short of drugs and all kinds of medical appliances, but the hospital was clean and they were making the best of a difficult situation. The cases were chiefly relapsing fever and convalescent typhus. The town hospital was a contrast in every way: the wards were crowded and filthy, the bedclothes were grimy; flies were everywhere, and the atmosphere on a hot afternoon with closed windows can be better imagined than described; outside one of the wards was a cesspool overflowing into the hospital grounds.

At Tiflis Colonel Wenyon and I were taken over the Georgian Municipal Hospital, a fine building in extensive grounds, with clean and well-arranged wards and adequate laboratories. The methods here were up-to-date and the standard of clinical work was high. The clinical material was excellent and we spent a long morning in the wards, seeing many interesting cases. From Tiflis we went up to Erivan to investigate the circumstances of a case of suspected cholera among our troops, and were shown round one of the military hospitals by an Armenian doctor. The chief clinical interest was in the wards where cases of "typhus recurrens," or relapsing fever, were under treatment. Of the numerous charts shown to us there were only one or two with more than a single relapse, notwithstanding the fact that no arsenical preparation was used in treatment. When asked why he did not give salvarsan, the doctor replied that it was unnecessary, as the cases were mild and invariably recovered without special treatment; he said he had never had a death from the disease, but I think the chief reason for withholding salvarsan was the fact that he had none to give. At many of the other hospitals I made the same inquiry and received a similar answer; it was clearly the local view that relapsing fever was a comparatively mild disease, and that deaths were very rare.

Lice in the Hospitals.

From Batoum I went north to Novarossisk and Ekaterinodar, which at the time was General Denikin's headquarters. At both these places in early June the prevailing disease was relapsing fever; there were also many cases of typhus in the hospitals, but the majority were in the convalescent stage. At Ekaterinodar some of the hospitals were well arranged, others were the reverse; a reproach common to all was the failure to keep the patients free from lice. The part played by lice in the spread of disease was well known, but when it came to practical measures there was a lamentable failure in the application of their knowledge. Real difficulties were present in the shortage of change of clothing and bedding, shortage of nurses, and sometimes shortage of water. The first of these was being remedied as far as possible by grants of linen from the British Military Mission, but little or no attempt was made to grapple with the louse problem, with the result that large numbers of the medical and nursing personnel fell victims to typhus. An incidence of 30 to 50 per cent. was regarded as a normal state of things; at one hospital in a vodka factory, with beds almost touching in unventilated and stuffy wards, all the personnel had had typhus, a

record of which they were proud, instead of regarding it as a mark of the inadequacy of their hygienic service. It is a curious illustration of the mentality of the Russian authorities that, while neglecting such obvious precautions, they were ready to experiment with unproved and speculative methods of prevention and treatment. At Ekaterinodar some of the personnel in typhus wards were being inoculated with what was described as a "vaccine" consisting of sterilised blood drawn from typhus patients at the date of the appearance of the rash. Good results were claimed for this procedure. Also cases of typhus were being treated with serum removed from convalescent patients three to five days after the temperature had become normal. A daily dose of 10 c.cm. was given subcutaneously for three to four days. The account of the benefits derived from this method of treatment was not convincing, and hardly justified the removal of large quantities of blood from those who were recovering from a grave and debilitating illness. At Novarossisk intravenous injections of cyanide of mercury, in doses varying from 0.001 to 0.01 g., were given in 2 c.cm. of water every second day; 300 to 400 cases of typhus had been treated in this way with alleged good results.

The hospitals at Constantinople were, on the whole, clean and well ordered in most respects, except in their nursing arrangements, which were far below the standard which we regard as essential. Everywhere there was a shortage of drugs and medical and surgical necessities, and all schemes for improvements and developments were held up for want of funds. The children's hospital on the outskirts of the town was a model of its kind, consisting of a number of separate pavilions standing well apart from one another in wooded park-like grounds overlooking the Bosphorus.

I cannot conclude my remarks without paying a special tribute to the D.M.S., Major-General Sir M. P. Holt, K.C.B., K.C.M.G., who was always ready with his advice and whole-hearted support in carrying into effect any recommendations made with the object of improving the details of the medical service, and whose unflinching interest in the clinical aspects of the work was of immense encouragement to all concerned in maintaining a high standard of clinical efficiency. I also wish to express my thanks to Colonel C. B. Martin, C.M.G., Brevet Lieutenant-Colonel J. A. Anderson, and Major W. R. Galwey, O.B.E., M.C., for supplying me with the figures and curves on which the foregoing statistical diagrams are constructed; to my predecessor, Sir J. Purves Stewart, K.C.M.G., C.B., for many kindnesses; to Major H. W. Wiltshire, O.B.E., D.S.O., and Major H. R. Evans, for valuable criticism and suggestions, and to officers-in-charge of medical divisions, and medical officers of the various hospitals, on whose willing coöperation in showing and discussing cases of interest so much depended in collecting the data on which this communication is based.

THE PHYSICAL ELEMENT IN THE PSYCHO-NEUROSES.*

BY JUDSON S. BURY, M.D. LOND., F.R.C.P.,
VISITING PHYSICIAN TO THE NEUROLOGICAL HOSPITAL FOR
PENSIONERS AT BRINNINGTON; CONSULTING PHYSICIAN
TO THE MANCHESTER ROYAL INFIRMARY.

ARTICLES and discussions on the pathology of the war neuroses show an increasing tendency to regard mental factors as of much greater importance than bodily, and to look to psychotherapy as the only certain remedy, leading often to a dramatic cure in a time varying from a few minutes to a few hours; it is unusual to find reports of cases which the author has found difficult or impossible to cure.

No one would deny the importance of psychical factors in nearly every disease. Even in such serious conditions as cancer or pneumonia we recognise the beneficial effects of cheerful words of encouragement. The beginnings of disease of the nervous system are frequently associated with, and overshadowed by, hysterical manifestations which may be removed by suitable explanation and persuasion. It is an interesting speculation whether an emotional shock would abolish for a time the severest suffering. For example, if the wife or the child of a man in the agony of angina pectoris or of a paroxysm of trigeminal neuralgia was killed before his eyes, would his pain suddenly vanish and for how long?

But in addition to the beneficial effects of psychical influences on disease, there is evidence that emotional disturbance is an important aetiological factor in maladies other than the neuroses. The symptoms of chorea or of paralysis agitans may begin to develop immediately, or soon after, some severe emotional shock. No doubt in many such cases pathological changes are already present in the nervous system, but there may be no clinical indications of the presence of such changes, the patient appearing to be quite well before the emotional shock. Jaundice is sometimes precipitated by fright, which shows the effect of shock on glandular organs. Some time ago, Sir Thomas Barlow told me of a boy, aged 10, previously well, who was all but run over, just getting on to the kerbstone of the path. That night he became very pale and within a fortnight died with all the characteristic signs of acute pernicious anæmia. These examples indicate that emotional disturbance may initiate serious and even rapidly fatal disease.

Frequency of Relapse in Discharged Neurotics.

Passing now to my experience of the neuroses, I have been much impressed by the frequency with which relapses have occurred in cases which had been discharged from Maghull, Seale Hayne, and other neurological hospitals, as either cured or improved. At the Brinnington Hospital Dr. R. L. Gamlen (the medical superintendent) and I have records of a large number. What is the explanation? What is the pathology of the cases which so easily relapse? A common type of case which tends to relapse often more than once may be outlined as follows:—

A strong young man, never ill before enlistment, is exposed to some nerve-racking incident at the Front, from which he never seems to recover completely. He is admitted to a neurological hospital suffering from extreme nervousness: his limbs shake and his sleep is much disturbed by horrible dreams. After suitable treatment, psychical and other, followed by occupation in the garden or in one of the workshops at the hospital, he gradually improves, and in a few weeks is discharged as either cured or nearly well. He tries light work, but after a week or two has to give it up, owing either to a sudden collapse or to a gradual return of his weakness and tremor. He has now lost his war-dreams and sleeps fairly well. He may be sent again to a neurological hospital where a further attempt is made to discover any mental complex which may account for his condition. Nothing abnormal is discovered; he improves, is discharged, and sooner or later breaks down again.

The inevitable conclusion appears to be the presence of some indefinable physical disorder; in some way or other his neurones or other parts of his bodily machinery must be out of gear. But whatever the pathology, it is clear that the removal of tremor, rigidity, or other

similar symptom does not cure the patient. His unstable condition may last for years, and we cannot use the term "cure" until the man is able to do his ordinary work with as little inconvenience as he felt before the war.

A Typical Case of a Severe Type.

The following case is an example of a more severe and less common type:—

The patient, aged 35, has been in Brinnington Hospital several months. He was blown up owing to the explosion of a shell in August, 1916, and soon after regaining consciousness began to suffer from severe pains in the head, back, and legs. Then he began to shake, and owing to this symptom and the pains he became unable to walk, and has never walked properly since. On admission to Brinnington, he was a typical rigid tremulous case. His extended legs were like iron bars, and his feet and toes were rigidly plantar flexed. At first the greatest force was required to bend his ankles, knees, and hips, and any movement brought on violent shaking of the limbs. By devoting three or four hours a week to him I have got the knees and hips a little looser, and with a great effort he can now draw up the legs in bed, but it is impossible for him to do this slowly; the movement is a sudden jerky one, and can only be performed by the most concentrated effort. He cannot abduct or adduct the limbs or lift his heels from the bed. If I hold up his heel, his leg being either rigidly extended or passively flexed, and slowly withdraw the support of my hand, telling him to keep the limb suspended, his greatest effort is unavailing; the leg jerks down suddenly on to the bed. When encouraged and subjected to firm pressure on the plantar surface of the toes he can slowly dorsi-flex the foot to a very slight extent; this is a great struggle, and is accompanied by a drawing up of the patella and a rigidity of the calf muscles; in fact, all his energy goes to the contraction of muscles antagonistic to the movement. When told to concentrate his mind on the muscles on the front of his leg, with the explanation that these are the muscles which bend the ankles, he says he feels as if he has nothing to pull at. Inability to move part of the limb is not, however, entirely due to contraction of muscles antagonistic to the movement. After the ankle, knee, and hip are forcibly bent, the calf muscles may become quite flaccid, but he is unable to relax the flexors of the limb; for example, he can maintain forced dorsi-flexion of the foot for any length of time, but cannot bend down the foot and toes without a sudden extension of the whole limb.

Arthur Hurst, Yealland, and other advocates of intensive and continuous treatment, would say that the treatment—suggestion, persuasion, and re-education of the muscles—instead of being limited to one or two hours on odd days, should have been carried on without intermission until the rigidity was overcome, however long that might take. The psycho-analysts would say there is probably some mental complex, the unravelling of which would quickly cure the patient. The reply to these criticisms is that the man came to us from Maghull, where for six months he had been treated by the fatigue method, by psycho-analysis, and by hypnotism. He states that he was hypnotised seven or eight times and that when recovering from the hypnotic state he was told to get up and walk, but was unable to do so. When he left Maghull, his condition was much as it is at the present time.

The prominent feature of the case is failure to innervate the muscles of the legs properly, and we may ask: Is this failure due simply to an altered mental state, or are there actual physical changes in some part of his nervous system?

As to the psychical condition, let me repeat that the case was thoroughly investigated and treated at Maghull, and that having had many talks with the man I am unable to suspect a mental complex. I am also convinced that he is very keen to try anything that will lead to his recovery. It is difficult to avoid the conclusion that there are some physical or chemical changes affecting his motor neurones and interfering in the normal relation between impulse and inhibition, changes which in all probability were set up by the effects of the emotional shock caused by the shell explosion. The observed faulty innervation gives one the impression that there is a block at some synapsis which prevents the proper transmission of cortical impulses to the lower motor neurones.

In some respects the patient's inability to relax or inhibit the innervation of his leg muscles reminds one of the phenomenon described by Kinnier Wilson¹ and Walshe in their article on "Tonic Innervation." They give a detailed account of three cases of cerebral lesion, in which the most striking clinical feature was the patient's inability to relax a given innervation in one or other muscle group. Thus in one case, if an object was grasped by the affected hand the patient was

* The main portion of this communication was given at a meeting of the Association of Physicians in Manchester on May 21st, 1920.

unable to relax the grip for a full minute or more, although he made powerful associated movements with the normal arm, and although the tendons of the antagonistic group of muscles could be seen to tighten. The lesion in each case was in the part of the frontal lobe adjacent to the ascending frontal convolution and was associated with slight but definite involvement of the cortico-spinal path, and with slight spasticity of the affected limbs. The greater the involvement of the pyramidal tract the less marked was the tonic innervation. Two of the cases were cerebral tumour, and after operation the tonic innervation disappeared with the development of a post-operative hemiplegia.

The authors suggest that the symptom is associated with diminution of function of cortico-spinal neurones probably owing to interference with the stimuli reaching them by paths from the psycho-motor area of the frontal lobe. They doubt whether the symptom ever occurs when the cortico-spinal system is intact, but they mention a case of Van Vleuten, which suggests that the specific functions of the pyramidal system may have been normal when the symptom of tonic innervation was first noted. In my case, therefore, it seems possible that although a definite organic lesion can be excluded, there may be a break between the cortical neurones which convey stimuli to the motor centres and the neurones which constitute the cortico-spinal paths.

The Physical Basis.

But in considering the pathology of muscular rigidity, we must not restrict our attention to the pyramidal system. We have been too apt to think of this as the only path by which motor impulses reach the lower neurones, in spite of the suggestion made long ago by Hughlings Jackson that in health the whole of the muscles of the body are doubly innervated both by the cerebrum and the cerebellum, a suggestion verified by Sherrington in animal experiments. We now recognise that motor impulses are transmitted not only from the cortex along pyramidal fibres, but also from other parts of the brain along extra-pyramidal tracts.

The tremor and rigidity of paralysis agitans, and of certain lesions of the mid-brain (Gordon Holmes²) and the corpus striatum (Kinnier Wilson³) are now attributed to lesions of one or other of these tracts. Thus there are many different ways in which impulses from the periphery may reflexly influence the lower motor neurones—the final common path, as Sherrington calls it, along "which all impulses, no matter whence they come, must travel if they are to act on the muscle fibres to which it leads. Reflexes originated at different distant points and passing through paths widely separate in the brain converge to the same motor mechanism—the final common path—and act harmoniously upon it." It is impossible to speak more definitely as to the situation of the lesion which leads to muscular rigidity, or indeed to the other symptoms of the neuroses, nor have we accurate knowledge regarding the nature of the lesion. This might be a disturbance of structure, as, for example, an inaccurate association of some of the neurones constituting either the pyramidal system or one of the extra-pyramidal paths, possibly due to interference with the normal rates of recovery at various synaptic regions, or to a disturbance of the chemical reactions of the blood and lymph which come into contact with the neurones.

The Biochemical Aspect.

The chemical aspect of the problem and the influence of the sympathetic nervous system are full of interest. The researches of Cannon and others have shown that emotions such as fear and anger are attended by disturbances in deep-lying organs, including a discharge of an increased quantity of adrenalin into the circulation; the adrenalin raises the blood pressure and transforms the glycogen in the liver into sugar. If these energising substances are not worked off by muscular action, it is conceivable that their presence in excess in the blood may lead to pathological effects, to a disordered action of both mind and body which later is expressed by tremors, by tachycardia, by starting at the slightest noise, and by terrifying dreams.

In some cases the continued over-action of the suprarenal and thyroid glands may produce a clinical picture similar to that of Graves's disease. Sometimes sugar is present in the urine, and there is ample evidence that emotional states are frequently attended by an increase of sugar in the blood.[†]

A vicious circle is established; the emotion produces disturbances in the viscera and glands, and these disturbances react on the emotional states, setting up a constant mental unrest. An important paper by Orr⁴ and Rows on the Interdependence of the Sympathetic and Central Nervous Systems throws additional light on this subject. They bring forward evidence to show that the situation of certain organic spinal-cord lesions is determined by disturbance of the sympathetic system, and they suggest that "certain so-called functional disturbances of the central nervous system may owe their origin, or if not that, their tendency to recurrence and permanency to the same mechanism." They quote von Monakow, who, while ascribing great importance to the psychogenetic factor in the neuroses, lays great stress upon the bio-chemical factor. Also Lugaro, who says: the "unconscious" is not necessarily that of the psycho-analyst, psychic unconsciousness; it is conceivably the result of chemical phenomena as unconscious and apsyche as any other.

Factitious Erythema.

As having some bearing on the influence of the sympathetic nervous system I would mention dermographism or factitious erythema, a symptom about which I have made numerous observations during the last 18 months. If a blunt instrument—say the end of a Yale latch-key—is drawn firmly over the skin of the front of the chest, or in the interscapular region the pallor produced by the pressure is immediately followed by red at its margins; in a few seconds the redness invades the pallid streak and becomes diffuse with blotchy edges; then the flush begins to fade and a central red line is left which has sharply defined margins, sometimes bordered by an area of pallor. The total duration of this phenomenon in health varies from three to five minutes. The erythema reaches its maximum development in Graves's disease, in some cases of which it develops into actual urticaria. Its minimum development is seen in adynamic conditions, as in the final stage of a fatal pneumonia, where only the faintish purplish streak can be elicited. Between these two extremes every variety in rate of development, in intensity and duration, may be observed in different diseases. Its mechanism is obscure; obviously the result of reflex action, it is probably an axone reflex—i.e., it does not involve a nerve centre, merely running up one limb of a bifurcating nerve fibre and down the other. But whatever its mechanism, variations in the tache must be related to variations in the reactions of the sympathetic nerves, which innervate the peripheral vessels, and to changes in the secretions from some of the ductless glands.

It has been of great interest to me to note that factitious erythema is very pronounced, not only in the "anxiety neuroses," but also in some cases of "conversion hysteria"; thus in two cases of hysterical contracture of the foot, the tache which was marked, lasted from 45 to 60 minutes. This surely indicates a general as well as a local change—in other words, that true hysteria is not wholly represented by a paralysis, an anaesthesia, or other local manifestation, as is stated by Babinski and Hurst.

I have never felt satisfied with their definition of hysteria as a condition in which symptoms are present which have resulted from suggestion, and are curable by psychotherapy. My observations on hysterical anaesthesia, especially in children, have prejudiced me against such a limited view, and I would refer to a paper on hysterical analgesia in children written by Sir Thomas Barlow⁵ nearly 40 years ago. The children varied in age from 2½ to 11½ years. Sensation had not previously been tested, and Barlow took every precaution in the testing. He found that in addition to

[†] See an article on Hyperglycemia in Mental Disorders, by F. H. Kooy, *Brain*, vol. xlii., part iii., p. 214.

the limb or limbs in which analgesia was so profound that strong faradism did not make the child wince, some other parts of the body showed a lack of ordinary response. It is difficult to believe that in such cases there can be the elements of expectant attention or of auto- or hetero-suggestion. It is easier to believe that in the state called hysteria there is a general alteration of the nervous system, and in some of the shock cases either a blood or a secretory gland change.

Conclusion.

In conclusion, the above remarks are meant to apply only to genuine cases of the neuroses. The difficulty in discriminating between malingering and a true neurosis is very great, and, as Buzzard⁶ says in his remarks on the diagnosis, we are very apt to be biased by our personal feeling towards the patient. He gives an amusing instance of this: a patient suffering from mutism was such a nice fellow that no one would call him anything but a case of hysteria, but his only successful attempt to speak was when he blurted out that he would rather be dumb for the rest of his life than go back to the front. True malingering—that is, conscious simulation—is rare. It is, however, often combined with true hysteria, or unconscious simulation, and it is such combinations that I think lend themselves most readily to dramatic cures.

I have dealt with the underlying physical basis of the neuroses, because there seems to be a tendency to lay undue stress on the psychical factor. At any rate, it seems likely that molecular disturbances of the nervous system and altered blood states largely account for the long duration of many cases and for the great tendency for symptoms to relapse on the slightest provocation, whether that be undue exertion, loud sudden noises, or family or business anxieties.

In the most common type of case I believe that better results will be attained by fresh air, sunlight, cheerful surroundings, and light work, than by continuous searching for a hidden mental conflict. Of the value of psycho-analysis in certain intractable cases where there are reasons for suspecting a repressed memory or complex, I am not competent to express an opinion. Nor am I tempted to undertake the necessary investigations when I read that a three years' study of the subject is essential, and that to unravel a complex, to trace some of its elements back, possibly to some incident in childhood, often a very muddy one, may occupy the constant attention of the psycho-analyst for at least several months, and sometimes for a year and even longer.

THE INFLUENCE OF SUGGESTION ON BODY TEMPERATURE.

By J. A. HADFIELD, M.A. OXON., M.B., CH.B. EDIN.

MORE than two years ago I published in this journal¹ a paper describing experiments in which blisters were produced by hypnotic suggestion. Since that time I have made the same attempt in perhaps half a dozen cases without success. But I have recently had under observation another case of the same kind in which a blister was formed even more rapidly than in my previous case. I do not propose to describe this experiment, for it was not dissimilar to the last. This case, however, showed a very remarkable susceptibility to suggestions of heat and cold, which was not purely subjective, but produced a rise and fall of temperature as measured by the thermometer. The temperature of both hands was taken with the bulb of the thermometer held firmly in the middle of the palm, and found to be—right, 89° F.; left, 90° F. Then suggestions of "cold" were made relative to the left arm. Subjective feelings of cold were

felt immediately, but no change in temperature took place for three minutes. Then the temperature began to fall, till it reached 85° in the left hand, whilst it remained at 89° in the right. This change took place in the course of ten minutes, and the thermometer was still descending when suggestions of "warmth" were made, which restored the temperature to 89° in the right hand.

Later in the day a much greater change of temperature was obtained by suggestion. The patient was taken out for a five-mile walk without gloves and carrying nothing, and with both hands free, in order to equalise the temperature in both hands. Suggestions were then made of "cold," this time to the right arm, for purposes of control. The arm immediately began to get chilly, subjectively and objectively. In half an hour the temperature in the left palm was 94°, whilst that in the right was 68°. It is interesting to note that this temperature—68°—was the exact temperature of the room at the time, the circulation having apparently no effect on the skin temperature. The right hand appeared and felt to the touch extremely cold, and great discomfort was produced. To the touch the right hand felt like ice, whilst the left hand was comparatively warm. Leaving the thermometer still in the palm of the hand, I then suggested the right hand warm again. Almost immediately the thermometer began to rise, till at the end of 20 minutes the right hand stood at 94° and the left at 95°.

A further remarkable incidence is that, though I have frequently hypnotised this patient, the suggestions of this experiment were made *entirely* in the waking condition.

Relation of Pain to Inflammation.

As already remarked, I had previously produced "suggestion" blisters in this patient, and a blister was also produced by touching the arm with a heated thermometer case, suggesting in the latter case that there would be no pain, either at the time or afterwards. The result was as suggested; but there was no inflammation surrounding the blister, as there was surrounding the painful blister produced by suggestion. This supports the view suggested in my article of November, 1917, that it is not the inflammation primarily that produces the pain or sensation, but the pain that produces the inflammation.

This principle was generally supported by a further observation. After two days the hypnotic blister became infected by the slipping of the bandages, and produced a more extensively painful and inflamed condition. By a word of waking suggestion the pain was abolished, with the result that in two or three minutes the inflammation was also reduced, and the hyperæmia and redness nearly disappeared. It was then found possible, by suggestion of heat and pain, to restore the wound to a painful and inflamed condition once again. The suggestion of "cold" had a more marked effect than that of "painlessness" in bringing about the reduction of inflammation.

Whilst I have mentioned these experiments in particular, they were not isolated, either in this or other patients. I frequently repeated the raising and lowering of the temperature of the arm in this patient. This phenomenon was produced in other patients, not only by myself, but by Captain G. de H. Dawson and Captain O. Connell at Ashurst Hospital. In these cases, curiously enough, we were able to *raise* the temperature of a hand, but could not *lower* the temperature by suggestion. It is further noted in the cases I observed that when we suggested "heat" to one hand, it was the other hand that *first* showed signs of rising warmth on the thermometer; and then the suggested hand would go ahead and "beat" the other, till there was a very marked difference between the two. The greatest range of temperature that I have observed is the one detailed above; but Captain Dawson claims to have produced a rise of 20°. This, however, was, I believe, in an arm which corresponded closely to the type known by Babinski as "reflex," with a wound and vascular changes present.

If these conclusions of the effect of suggestion on body—and particularly cutaneous—temperature can be estab-

¹ THE LANCET, 1917, ii., 678.

lished it will surely be of great import, both to physiology as a whole and to dermatology in particular. Have not some skin diseases been known to be associated with the neurotic constitution? If the auto-suggestion of a neurotic can influence the circulation and depress the nutrition of the skin in the way that our hetero-suggestion has done in these experiments the connexion becomes obvious. The experiments described above are very tentative and suggestive; there remains the more important experiment of determining whether suggestion can raise and lower the whole body temperature. My patient, Mrs. N., to whom my thanks are due for these experiments, performed at considerable discomfort to herself, has placed me under the greater obligation of offering herself for further experimentation.

SUGGESTIONS FOR THE MASS TREATMENT OF HOOKWORM INFECTION.¹

BY DR. S. T. DARLING,

PROFESSOR OF HYGIENE, FACULDADE DE MEDICINA E CIRURGIA DE
S. PAULO.

In the course of the work of the Malaya Board in the Far East some new data were obtained on hookworm infection and its treatment and on malaria, data of value to the doctor, the employer of native labour, and the administrator. The Malaya Board consisted of Dr. M. A. Barber, Dr. H. P. Hacker, and myself as chairman. It worked in Malaya, Java, and Fiji under the auspices of the British Colonial Office and the Netherland Indies Health Department, and was supported by the Rockefeller Foundation. The object of its researches was to ascertain to what extent hookworm infection affected the working efficiency of the people in the countries named. Our work disclosed the fact that hookworm infection exists to a greater extent in the tropical East than is generally recognised. In most communities and districts the great bulk of the people are agriculturists. Practically 100 per cent. of adolescents and adults of this class are infected with hookworm.

It was shown very positively that there is a correspondence between the degree of infection—that is, the actual number of worms harboured—and the amount of blood loss or anaemia suffered. This loss was frequently hidden or undetectable due to abundant food, opportunities for rest, and to active hæmatopoiesis in certain resistant individuals, but the drain and loss were none the less real, and constituted a tax on the vital powers.

Working with a large number of persons from whom practically all the hookworms had been expelled by vermifuge and counted it was estimated that a given number of hookworms produced a corresponding amount of blood loss. A given number of worms produced more anaemia among children than an equal number in women, and more among women than an equal number in men. Furthermore a given number of *Ankylostoma duodenale* was found to produce a greater degree of anaemia than an equal number of *Necator americanus*, probably due to the more severe hæmorrhage caused by the former worm. Finally, it was estimated that about 12 hookworms are required to cause a loss of 1 per cent. hæmoglobin. When the number of worms harboured is considerable the anaemia caused is evident and measurable; when but few worms are harboured the blood loss may not be detectable.

It is extremely important that emphasis be placed on this fact that hookworms are constantly causing losses of blood through multiple small worm-bites.

Observations made by the Malaya Board are of such a character that the amount of blood loss caused by hookworms and the resulting loss of efficiency can be demonstrated graphically to planters and other employers of labour. Using a rigorous method of diagnosing cases of infection by the administration of

vermifuge and comparing it with the less accurate method of microscopic examination of feces for ova it was ascertained that a larger proportion of the inhabitants of tropical countries are infected with hookworms than is generally suspected. For example, where the microscopic examination revealed in the hands of the lay microscopist an incidence of 75 per cent. infection, diagnosis by vermifuge revealed an incidence of 97 to 100 per cent. The usual method of diagnosis of hookworm infection by microscopic examination of stools for ova does not convey a quantitative idea of the severity of the infection—i.e., the number of worms harboured by an individual—and the degree of injury wrought on the patient. The grade of infection existing runs from 1 to a thousand or more worms. In some villages the average is 40–50 or less; in others 100–150 or more; different villages and special groups of people present infections of different grades of severity.

Diagnosis by means of vermifuge disclosed another fact of extreme importance—namely, that many persons are harbouring a large number of worms, and, consequently are suffering unconsciously from a severe drain in proportion to the number of worms harboured. Thus, a notion was derived not only that oftentimes a higher degree of infection existed than was suspected, but a working knowledge of the number of worms actually being harboured (frequently large) by the people of a locality was obtained. In campaign work it is important to ascertain the number of worms being harboured, for it is more desirable to institute campaigns for treatment in communities where the infections are heavy than where they are light.

The therapeutics of several vermicides, more particularly chenopodium, were investigated by a method in which the efficiency of the drug is expressed by the percentage number of worms a given dosage is able to remove out of the total number harboured. The vermicides could thus be compared one with another according to the actual number of worms removed—the percentage of total worms removed. This affords a more direct and trustworthy index of the efficiency of a vermicide than microscopic examinations of feces for ova. Chenopodium was found to be more effective than thymol in killing hookworms, and it was even more efficacious in expelling ascaris and other helminths such as oxyuris, trichiuris, and trematodes. Other things being equal, it is better to use the most efficacious drug.

Toxic symptoms are elicited with all vermicides in the higher dosages; it is therefore necessary to reduce the dose given to as small an amount as possible. Chenopodium retains its vermicial efficiency upon reduction in dose better than thymol, and this is another reason for its employment. The Malaya Board ascertained that the dosage, 1.5 c.cm. oil of chenopodium, was highly efficient and but slightly toxic, sometimes causing transient dizziness and vomiting. Two treatments of this dosage removed 99 per cent. of the hook-

¹ This paper is based on work done in Java and Brazil, where I was assisted by Dr. M. E. Barnes and Dr. W. G. Smillie, and in part on work done in Malaya and Fiji with Dr. M. A. Barber and Dr. H. P. Hacker. Certain data are extracted from our joint report to the International Health Board which will appear later.

worms present, and this is the dosage recommended. It has a more uniform action—that is, fewer failures occur with it than with thymol; it has a more powerful effect on *A. duodenale*, and is less unpleasant to take than thymol. Not only is the cost of oil of chenopodium much less than that of thymol to effect a given result in worms removed, but oil of chenopodium being a fluid, its vermifugal powers are more uniformly applied, and relative failures in reaching and affecting the worms are less common than with the solid thymol, the spreading powers of which are limited by its physical state. This is an extremely important point to be considered.

The Malaya Board found thymol less effective than chenopodium, and in the following degree (see chart). When the effect on ankylostomas and necators is charted, the more rapid fall in efficiency of thymol over chenopodium with the reduction of dosage is well shown, both in regard to necator and ankylostomas.

Administration of chenopodium in massive or broken doses.—Treatments with 2 c.cm. chenopodium in one massive dose were compared with those in which the oil was given in two broken doses; the difference in efficiency, 95.8 per cent. in the former and 96.15 per cent. in the latter, is slight. Field tests carried out by Dr. Smillie in Brazil show that there is an advantage in the broken dose, as it favours more prolonged contact with the worms, and gives a higher yield of worms removed.

Omission of the preliminary purge.—The omission of the preliminary purge did not materially alter the efficiency of chenopodium in our series when the latter was given in broken doses, but the number of cases was too small to be conclusive on this point.

The purge.—Magnesium sulphate answers the purpose very well; $\frac{1}{2}$ to 1 oz. may be given. Castor oil should not be administered with chenopodium, for it increases the toxic symptoms such as dizziness and deafness. This is probably due to oil of chenopodium being soluble in the castor oil and being absorbed more readily than when given with magnesium sulphate.

With this information at hand, based on experiments in the hospital ward and prison it would seem wise to increase the volume of evidence by conducting additional experiments along the same lines in the field. This is being done. Meanwhile certain modifications in the method of treatment as at present carried out, which would seem to be warranted, may be outlined.

Plan of Treatment.

Personal experience among Chinese, Malays, East Indians, Polynesians, Kaffirs, and Brazilians leads me to believe that an active campaign on an intensive plan rather than a passive dispensary programme must be prosecuted. The people—all the people—must be reached and everyone treated, for they are usually infected with hookworms or other helminths.

Taking the adult agricultural population within the tropics as a whole 90 to 100 per cent. are infected with hookworm and nearly 100 per cent. with helminths. The only place where I encountered a really light infection was in mountain villages in Java and Sumatra. Here only 50 per cent. of the people were infected, and they were harbouring very few worms. The incidence of infection is usually so high that the method of detecting infection by microscopic examination is, as ordinarily carried out, hardly necessary. Consequently within the tropics and where, as in mines and elsewhere, a high incidence of infection prevails the population should be treated *en masse* by an intensive method, and probably without the unnecessary preliminary of examining the stools for ova.

The importance of treating heavily infected communities first.—In inaugurating a campaign against hookworm infection in a tropical country it would seem more humane to select for treatment those communities in which the people are carrying the heavier burden of infection, as, for example, among the agriculturists working in cane, rubber, or coffee. The town-dwellers and others are usually more lightly infected and their case is not so urgent. There is no objection in special instances to treating townspeople, installing latrines, and undertaking educational work for purposes of influencing the agriculturists by means of an example.

In Java, taking men as a class, I found that in four of the kampongs in the City of Batavia the average number of hookworms harboured per man was 50, not a large or relatively incommensurable number. In the mountains of the Preanger Residency, in one of the mountain villages, the men harboured only eight worms apiece. In Sumatra, from the Batak highlands, the average was 5.7. On the other hand, in two representative agricultural *dekkans*, of which there are thousands in the East and hundreds in Java, the average numbers of hookworms per man were 378 and 235 respectively. Such numbers constitute a very great burden to the individual and seriously interfere with his health and working efficiency.

There can be no question but that such villages as the last two mentioned should be given the benefit of treatment before the mountaineers or the town-dwellers. The information required to ascertain the grade of infection can be obtained within three days and without the aid of microscopists.

If treatment is to be extended rapidly over a vast population, as it should be, the method of treatment must be further simplified, standardised, and cheapened. Millions of people in India are waiting for treatment. The same is true of Brazil and other tropical places. The customary method of examining stools microscopically by a native lay microscopist is expensive, time consuming, and yields untrustworthy results.

Reducing the Cost of Treatment: Economy of Personnel.

Comparing thymol and chenopodium in the dosages in which they yield nearly equivalent results—i.e., 1.5 c.cm. of chenopodium, yielding 97.9 per cent. of worms, and thymol, gr. 90, yielding 97.8 per cent. of the worms present, the cost of chenopodium was but \$0.027, while that of thymol was \$0.135, or exactly 5 times as much. This is based on the cost of thymol at 0.15 cents a grain, and oil of chenopodium at 1.84 a cubic centimetre.

If the method of treatment can be cheapened, the money saved may be used to extend the campaign to places where severely infected people are still waiting for treatment. The Malaya Board inquired into the accuracy of the native microscopist in the East and found that his reports could not be relied on. He was insufficiently trained, his diagnosis was not true, and through a desire to please and to conciliate he would make his microscopic findings fit what he thought was desired. But more than this and of as great importance is the fact that microscopic examination, even when carried out by trained microscopists using a special technique designed to concentrate the ova and thus facilitate the work of detection, fails to detect every case of infection.

This may be seen from the following table: (A) In which the microscope work was done by an expert microscopist using special technique and a re-examination of negative specimens. (B) In which the examinations were made by native or lay microscopists.

Comparison of Results of Microscopic Examination of Fæces for Ova with those of Worms after Vermifuge.

Race.	Result of microscopic examination for ova.		Result by recovery of worms after treatment	
	No. of exams.	Per cent. positive.	No. of exams.	Per cent. positive.
(A).—F.M.S.

" children ...			2	100
Fijians, males ...			20	100
" females ...	756	78.7	4	100
" children ...			9	100
(B).—Brazil.				
Brazilian boys ...	72	86.2	72	100

These results of microscopic examinations in the laboratories of the I.H.B. are made by, or under the

supervision of, trained and experienced men. The microscopic technique, when placed in less experienced hands, may be expected to yield results still less trustworthy.

In practice, then, the result of a campaign based on microscopic diagnoses as carried out is to treat thoroughly only a portion of the infected population; the remainder as carriers of infection continue to be a menace. Diagnosis by microscopic examination will vary in accuracy, depending on the skill, persistence, honesty, and technique of the microscopist, and it will probably yield evidences of infection varying between 4 and 23 per cent. less than actually exists. If the microscopists fail to detect this number of instances of infection before treatment, they will probably make almost as great an error in the examinations made after treatment when the number of worms remaining are fewer. Consequently the "cures" based on the microscopic examinations made after treatment are not always valid. The infected persons whose infection the microscopist has failed to detect are not given an opportunity to receive treatment for hookworm, ascariis, tenia, clonorchis, or other helminths with which they may be infected. Moreover, they are given the impression that they are free from infection; yet this large number of infected persons continues to seed their environment, thus leading to their own continued re-infection and to the re-infection of others, including those who have been treated. From a public health standpoint this cannot be regarded in any other light than as unsatisfactory.

The present practice is to treat for "cures"—that is, cases reported as negative by the microscopist after treatment and microscopic examination of stools for ova. But every lot of "cures" contains the error of the microscopist; and besides, a "cure" does not properly indicate the amount of work done in removing worms, nor the benefit received by the patient from the treatments given.

In a recent test made in Brazil we noted that "percentage of cases cured" was not a good indicator of the number of worms removed by treatment, for whereas only 28 per cent. of cases were "cured" by a first treatment of chenopodium, 90·8 per cent. of their hookworms were actually removed, and when only 49 per cent. of the cases were "cured" by two treatments 97·1 per cent. of the hookworms were actually removed. It is evident that worms removed is more important and is a better criterion of work accomplished than the microscopist's "cures." When we consider the millions of people in the tropics in need of treatment and the slow progress of the campaign work, the last few hookworms remaining after two or three 1½ c.cm. chenopodium treatments are probably doing too little harm to waste time and money over.

The Importance of Mass Treatment of Inhabitants Instead of Intensive Treatment of Individuals.

It is not necessary to remove the very last few hookworms, for it is not the two or three worms a man may retain after treatment that are doing the great harm, but it is the 150 or more worms that are busy in the great mass of untreated humanity in tropical and subtropical lands. It is not usual in practice for all the worms to be expelled by treatment; they are reduced to a minimum—a condition highly desirable from the patient's point of view. The public health officer wants every last worm removed from everybody, but that is impossible of achievement. In every district a good number of persons escape treatment; they happen to be ill, are absent, remove to another district, or enter the district after the census has been taken. We may say that 6 per cent. of the population remain untreated. This number, added to the number of positive cases which the microscopist failed to detect, makes a total of approximately 19 per cent. of the total population remaining infected. This number of carriers the public health officer does not get rid of by present methods. Thus while he is striving for "cures" in four-fifths of the population, the other one-fifth escapes him to continue infecting their environment.

Now, by reducing the dosage of chenopodium to a quantity safe and free from toxic manifestations and by giving two or three treatments, and thus removing 97-99 per cent. of the worms, it will be possible to treat the *entire population* in safety, and we shall be making a close approximation to the desideratum of the public health officer.

Hookworm Treatment in Malarial Communities.

Hookworm treatment will oftentimes have to be carried out in communities where more or less severe malaria coexists. It is, in fact, highly important that treatment should be carried out in these places, for hookworm infection appears to be more severe in those cases of malaria which are associated with a palpable or enlarged spleen. It may be that infection with a relatively large number of hookworms favours the development of splenic enlargement and the continuation of this state after acquiring malarial infection, or malaria may predispose to severer hookworm infection; in any case, the fact remains. In Batavia Jail I found that 63 men with negative spleens, though constantly exposed to malaria, had an average of 58 worms apiece, while 14 men with enlarged spleens similarly exposed to malaria had 120 hookworms apiece; 29 men with palpable spleens had 98 hookworms apiece. We have, then, not only a strong reason for treating these cases of hookworm infection whose anæmia is usually so severe, but a reason for treating malaria as well.

It must be explained to the people that their anæmia and debility are not only due to hookworm infection, but to a great—even greater—extent to malaria, and that while it is of great benefit to the individual to be rid of hookworm infection improvement will not follow unless malaria is gotten rid of at the same time. All the anæmia encountered among the people should not be attributed to malaria nor to hookworm. Underfeeding in rural communities plays an important part in contributing to the general anæmia and debility due to these three handmaidens of death.

In Fiji it was estimated that underfeeding resulted in a group of East Indians having 9·5 per cent. lower hæmoglobin than another well-fed group of the same race. Each group harboured the same number of hookworms. In the jail in Batavia taking the 109 treated prisoners as a whole, their hæmoglobin was 25·8 points per cent. below normal (95 per cent.). I estimated that 6·8 points loss were due to hookworm infection, 10·3 points to malaria, and 8 points loss were due to hard labour. In many rural communities the people or the employers of labour can be instructed in the means used to prevent malaria. In the Far East members of the Malaya Board investigated malaria and hookworm infection at the same time. It was their practice to make a malarial survey of each estate visited. They were frequently of service to planters by being able to point out the breeding-places of anopheline malarial carriers, and advise them of the measures which might be taken. In Java during the hookworm survey a malarial survey was made of each district visited, and the amount of malaria existing in the district estimated before beginning the treatments and worm counts. In these backward or neglected communities, where rural hygiene still remains in a primitive state, the men in charge of hookworm prophylaxis have a splendid opportunity to advise the people as to the malarial measures most suitable for the locality. Oftentimes a simple filling, ditching, or drainage operation is all that is needed to destroy a bad breeding-place and to rid the community of its greatest menace.

Suggestions for Conducting a Campaign.

It is first advisable to ascertain the degree of infection in different regions and among different classes of the population in order that groups most severely infected may be treated first. The local medical authorities should be consulted to get the benefit of their knowledge on the severity of cases of infection already encountered. A general inspection of the district or country should be made with the local medical men to ascertain the topographic, climatic, and economic features. The district or country should be split up in such a way

that characteristic groups of the people may be examined and sampled. Plantations and estates cultivating sugar, coffee, rice, or rubber, mining populations, fishing villages on the coast, town dwellers, should be treated separately. Attention to the character of soil, altitude, temperature, distance from sea, and proximity to malarial localities, ethnic stock, relative prosperity or economic position, are among the categories which should influence one in dividing the people into groups for sampling.

In coöperation with the administrative medical authorities, a survey may be made. The population is either mustered or visited domiciliary; the former is preferable whenever possible. A spleen census is taken, and hæmoglobin determinations are made, and blood is withdrawn at the same time for determining endemic index (malarial plasmodia). A representative sample of the population is now chosen; this is based on the results of the spleen and hæmoglobin determinations, and they are treated and their worm counts ascertained; 3 c.cm. of chenopodium is the adult dosage for this. The sample should consist of men, women and children. The worm-count will disclose the number of worms actually being harboured. A knowledge of this is of greater importance than the incidence of infection as determined by the lay microscopist.

With a knowledge gained of the degree of infection actually existing among the different classes of people and in different communities as influenced by occupation and economic conditions, a selection can be made of the districts or classes of persons which it is desired to treat first, naturally with the object of treating first those persons in whom the infection has been demonstrated to be most severe.

All grades of infection will be encountered in the surveys. Some grades will call for immediate treatment, others for deferred treatment. This will have to be thoroughly worked out in the field in accordance with the actual findings. Tentatively it may be said that the grades of infection may be rated as: mild, 50 and under; moderate, 50 to 100; severe, 100 and over.

I should recommend that communities in which the adults have an average of 50 or less do not urgently require treatment, while those with more than 50 should be treated. In carrying out treatment the two-treatment plan may be pursued, microscopists being dispensed with. Every person in the group, excepting very young children, should be treated. Persons ill with chronic nervous diseases may be treated with thymol or other vermicide. Pregnancy and severe anaemia are not contra-indications to the administration of chenopodium. The drug and dosage is chenopodium 1½ c.cm., given in single or broken doses in hard gelatin capsules. The preliminary purge before medication may be omitted, but in this case the evening meal should be light and food then interdicted until after the post-vermicidal purge, which may be given two to three hours after the exhibition of the chenopodium. The post-vermicidal purgation should be very thorough, for it is extremely important that the chenopodium, being a neurotoxic drug with cumulative powers, should be as thoroughly expelled as the worms, and at the earliest possible moment after the drug has accomplished its purpose on the worms.

In hookworm control, if permanent results are to be achieved, prophylaxis as well as treatment of infection must be considered. On first view it would seem that the installation of latrines and the education of the people in their use and in a better personal hygiene requires that the personnel attached to the post should remain in the village long enough to have thoroughly impressed the inhabitants with the importance of the work. They should probably not leave after merely treating them. Nevertheless, important as is the education of the people in a better personal hygiene, the riddance of the hookworm handicap of the people at large is of greater immediate importance. This handicap cannot be fully appreciated by those who are conducting campaigns, unless they actually study the subject by means of the hæmoglobinometer and by making worm counts of representative samples of the

population, so as to familiarise themselves with the actual number of worms being harboured by the people. When this is done the oftentimes enormous amount of curable debility and economic inefficiency caused by hookworms is made apparent and may be estimated numerically.

With a knowledge of this debility, as revealed in samples of the population, comes the desire to relieve all the people of it at once, without waiting for the educational part of the programme.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TWO CASES OF PARALYSIS AGITANS OCCURRING BEFORE THE THIRTIETH YEAR.

By E. DANVERS-ATKINSON, M.B. LOND.,

AND

CECIL WORSTER-DROUGHT, M.A., M.D. CAMB.,

NEUROLOGISTS TO OUT-PATIENT DEPARTMENT FOR NERVOUS DISEASES, BETHLEM ROYAL HOSPITAL, AND TO MINISTRY OF PENSIONS.

PARALYSIS agitans (Parkinson's disease) rarely develops under the age of 40, the usual age-incidence being between 50 and 70 years. It is true that a few cases have been recorded in patients under 19, but in some at least it is by no means certain that the diagnosis was correct.

CASE 1.—E. S., aged 30, seen in March of this year. There is no family history of mental or nervous disorder beyond the fact that his mother is said to have died from a "stroke" at the age of 52. He is married and has one child, aged 4, quite healthy.

History of condition.—He states that he has had no previous illnesses of importance, always having been healthy and played games such as cricket and football. He enlisted in the army (infantry) in June, 1916, being classified "A," and proceeded to France in October of the same year. During the winter of 1916-17 his left arm gradually became "weak" and somewhat stiff, but he was able to carry on at duty until September, 1917, when he was slightly wounded in the right arm by a fragment of shell. The wound, however, became septic, and on this account he was invalided to England. On leaving hospital about two months later he states that he "went to pieces"; his limbs rapidly became increasingly stiff, the character of his speech gradually changed, and he experienced great difficulty in getting about owing to general muscular weakness.

Condition on examination.—Cranial nerves: Pupils moderate in size, reaction to light somewhat sluggish, consensual reactions present, accommodation normal; no nystagmus, ocular muscles normal, fundi normal. The face is immobile and expressionless, the mouth invariably slightly open, with occasional dribbling of saliva. The voice is monotonous and the speech hurried. No sensory disturbance. Motor attitude: The head is bowed forward, the back arched, the upper arm held slightly abducted, the elbows flexed, the forearms partially pronated, the wrist and metacarpophalangeal joints slightly extended, and the thumb opposed towards the index finger; the hips and knees are slightly flexed. Rigidity of the spinal muscles and limbs is pronounced, and in turning round he rotates as one mass, without movement at the hips or shoulders. "Pill-rolling" tremor is occasionally present, and can be inhibited for a short time on voluntary effort; there is also a periodical antero-posterior tremor of the head. The gait is festinant, and propulsion and retropulsion are both marked. The wrist-, supinator-, biceps-, and triceps-jerks are all somewhat brisk, those on the left side being slightly greater than those on the right. The knee- and ankle-jerks are moderate and equal on the two sides, and the plantar reflexes are flexor. The abdominal and epigastric reflexes are brisk and equal. There is no incoördination of the upper or lower limbs and the sphincters are unaffected. Mentally, he is apathetic, egocentric, and somewhat depressed, but otherwise normal. The heart, lungs, and digestion are normal. The blood-vessels are not unduly thickened, and the systolic blood pressure is 135 mm. Hg. The urine shows no albumin, sugar, nor abnormal deposit. The blood serum yields a negative Wassermann reaction.

CASE 2.—H. B. T., aged 30. There is no history of mental or nervous disease in the family, nor did the patient suffer from any illness prior to 1914.

History of condition.—The patient enlisted on the outbreak of war in 1914 and was sent to Malta on duty. After serving 21 months there, he was invalided home suffering from nephritis; he received treatment in hospital, and after a few weeks was able to return to duty. In May, 1916, he fell from his horse, and states that he sustained "concussion of the brain." This was followed by "traumatic neurasthenia," the symptoms consisting of headache, palpitation, and general nervousness. Finally, he was invalided from the army in January, 1917. About ten months later, he noticed a tremor beginning in the fingers of his left hand, and

states that the left arm "trembled" at night when in bed. After four months the tremor of the left arm had become almost constant, and the same symptom was beginning in the lower limbs. A medical board, in October, 1918, noted the above symptoms, together with a progressive loss of power in the legs, and the facial expression was reported as being "fixed."

Condition on examination (1920).—He complains of general stiffness and weakness, the latter being especially pronounced in the left arm and leg, palpitation, vertiginous sensations, and tremulousness. Cranial nerves: Pupils equal and react normally, no nystagmus, ocular muscles normal, fundi normal. The face shows the characteristic immobility and lack of expression described as "Parkinson's mask." His speech is dull and pitched in a monotone. There are left-sided hyper-aesthesia and hyperalgesia, and cold is felt more acutely on the left side. Motor attitude: The trunk and limbs are held rigidly, and all movements are executed with marked slowness. The gait approximates to the spastic type, but without shuffling of the feet, and in turning patient moves as one piece in a statuesque manner. Propulsion and retropulsion are well marked. There is a slight tendency to a kyphotic attitude, and also for the flexors of the forearm to overbalance the extensors. He exhibits a typical "pill-rolling" movement of the left thumb and forefinger with a rhythmical tremor of the left forearm and leg of flexion-extension type. His control of these tremors varies, at times voluntary effort will control the tremor for a short period, an exacerbation following the period of control, while at others the effort only serves to amplify the tremor. There is considerable weakness of the left upper and lower limbs, particularly the left hand-grip. The wrist, supinator, biceps, and triceps jerks are normal and equal, the knee- and ankle-jerks brisk and equal, and the plantar reflexes flexor. The epigastric and abdominal reflexes are also normal and equal. There is no incoordination of upper or lower limbs and the sphincters are normal. Mentally he is self-centred but otherwise normal. The heart, lungs, and other viscera are normal, the systolic blood pressure is 160 mm. Hg, and the urine pale, of specific gravity 1002, and shows the presence of albumin.

Remarks.

From the above description of these two cases it will be seen that the syndromes closely related to paralysis agitans; and more likely to be met with early in life—such as Wilson's lenticular degeneration, Hunt's and Vogts' syndromes—can be excluded. The cases are of interest not only on account of the unusually early age, but because both patients were soldiers, in whom true paralysis agitans is very rarely seen. In four years of army neurological work during the war, one of us (C. W.-D.) did not meet with a single case of the disease (although many examples of functional nervous disorder were received erroneously diagnosed as paralysis agitans), and Dr. A. F. Hurst informed us last year that his experience had been similar. Further, at the Special Neurological Board (Ministry of Pensions), where many cases of disease of the nervous system are seen daily, no example, excepting the cases here recorded, under 50 years has been met with. This is of importance, as trauma and "shock" are often said to be exciting causes of paralysis agitans.

"CENTRAL" PNEUMONIA IN A CHILD OF TWO.

By H. O. GUNWARDENE, M.B., B.S. LOND.

THE unusual features of this case are: (1) that the crisis did not occur till the fourteenth day; (2) that the pneumonia was of the central variety and the physical signs of consolidation did not appear till the ninth day; and (3) that the temperature was maintained at two levels during the course of the illness for about nine days between 103.5° and 104.5° F. and for five days between 102° and 103°; the fall to the lower range suggests the crisis following the inflammation of the area of lung primarily involved, masked by the fever due to the subsequent involvement of another area; there is also apparent the so-called precritical rise before the arrested crisis. (See Chart.) The real crisis is a protracted one.

Notes on the Case.

Doris J., aged 2, who had been under my care for some time for another complaint, was brought to me on April 9th, having been sick twice that day and very drowsy. History of two days' illness. Temp. 103.4°; ale working; pulse 140 (counted at apex); respirations 50; nil in chest, abdomen, throat, or elsewhere; bowels not open. Given ol. ric. drs. 3 stat, and confectio sennæ. April 10th: As above; no physical signs; ? central pneumonia. 11th: As above. Slight impairment of note over right infrascapular region along line of interlobar fissure. Child seems comfortable, but takes very little nourishment. 13th: Restless, sings in sleep, slight cough; tepid sponge b.d.; is visited daily by nurse. Given mist. ipecac. ammon. with pot. brom. six-hourly, aspirin at night. Icebag to the head. 14th: Pallid; good heart sounds, no dullness to right of sternum; respirations 60; note impaired as before. Brandy m. 30, six-hourly. 15th: More pallid. Restless at times; impaired note along line of fissure as well as above it, and also over

right mid lobe. 16th: Dullness marked; distant bronchial breathing over infrascapular region; phenazonum gr. 3 at 7.30 p.m. 17th: Physical signs as above, with a few fine crepitations at the end of inspiration, ? pleural. Attacks of breathlessness fairly frequent. Strychnine hypodermically b.d. Appearance much better and breathing easier after strychnine. 18th: Restless at night; bronchial breathing, also in front above fourth rib; cough loose; colour still bad. 19th: "Had a very bad night," "fighting for breath"; colour bad; note impaired below line of fissure; markedly dull above it, but no fluid resistance. Explored with negative result. Oxygen p.r.n. Mist. ammon. c. ether. 20th: Little better, had better night. Pulse, respirations, lung as before. Heart, no dilatation. Strychnine and oxygen discontinued. 21st: Child said to be in pain

April 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25.

Dotted line shows fall due to tepid sponging. X Fall due to phenazonum, gr. iii. * Explored.

and restless. Nothing found to account for pain. Seems comfortable. Temp. 100° at noon; evening temp. 97°. Pulse 120, respirations 30; much stronger; colour good. 22nd: Note still impaired, but better; few creps. behind and bronchial breathing in front. Given mist. ipecac. ammon. 24th: Child well; a few fine, distant creps; still slight impairment on right side.

Dr. Still¹ refers to a case in which the fever lasted 15 days; and Dr. Pye-Smith, in Clifford Allbutt's "System of Medicine" says it may last as long as 26 days. Tepid sponging was employed, as I was reluctant to leave the child with a high temperature in the absence of a nurse, in view of the possibility of it rising higher. Aspirin on two occasions gave the child definite relief, but had little effect on the temperature, whilst phenazonum, used once only, caused a fall which lasted three hours and gave marked relief. The heart was strong throughout the illness. The exploration was done to exclude a possible interlobar empyema, suggested by the bad colour of the child on April 18th and 19th and the frequent attacks of dyspnoea, though sweating was absent and the chart did not indicate pus. Osler's² statement that empyema should be suspected if the fever persisted beyond the tenth day encouraged the exploration. The pulse and respirations did not fall with the temperature. The child is now perfectly well, with normal pulse and respirations.

I am greatly indebted to the staff of the Fulham District Nursing Association, whose invaluable services to the poor make possible the home treatment of cases of this kind without diminishing the chances of recovery.

² Principles and Practice of Medicine.

ROYAL VISIT TO A MEDICAL SCHOOL.—H.R.H. Princess Mary paid an informal visit to the London (Royal Free Hospital) School of Medicine for Women (University of London), on July 1st. She was received by the Dean of the School, Dr. Louisa Aldrich-Blake, Dr. May Thorne, and Miss L. M. Brooks. The Princess made a complete tour of the building, and showed much interest in the arrangements made for the residence of students, and in their work before and after qualification.

Reviews and Notices of Books.

L'INFECTION BACILLAIRE ET LA TUBERCULOSE

Chez l'Homme et chez les Animaux. By A. CALMETTE.
Paris: Masson et Cie. 1920. With 31 text figures
and 25 coloured plates. Pp. 620. Fr. 55.

WHETHER such a book as this is really necessary just now might be open to question; if it is a luxury it is a very nice one—and appropriately expensive. Roughly speaking, it contains all that the author thinks worth consideration about the tubercle bacillus and tuberculosis from the point of view of the laboratory worker and sanitarian; diagnosis by other than laboratory methods and treatment are not dealt with. Practical details are given fully in a useful way, and the large problems of infection and resistance are treated in a broad and eager spirit. The considered opinions of one who has been so much occupied with the subject will be received with respect. Some years since the author caused a stir by denying the importance of direct aerial infection of the lungs, and it is interesting to find that he still thinks that in the vast majority of cases infection is primarily lymphatic, the bacilli gaining entrance by the digestive tract and chiefly through the buccal, pharyngeal, and intestinal mucosa. He emphasises the point that ordinarily adult tuberculosis is greatly modified by the fact that its processes evolve in an individual already infected more or less and partly immunised, partly sensitised. He evidently thinks that quite enough fuss has been made about the distinction between human and bovine bacilli, and dismisses the question whether tuberculosis is catching or not with the simple truth that tuberculous infection is caused only by the tubercle bacillus. The final chapter gives an admirable summary of his outlook on prophylaxis. The whole point is, he says: 1. To control the dissemination of bacilli; the danger comes not only from those with manifest phthisis, but from all the host of people who, often without symptoms, are infected and intermittently excrete bacilli; every human or bovine who reacts to tuberculin is a possible source of evil. 2. To find some means of deliberately producing the resistance which is developed by the common small benign infections of childhood. The gospel is definite if not very surely founded in all its details; perhaps good gospels seldom are. English readers will miss any discussion of the relation between silica dust and pulmonary tuberculosis. Its practical importance has probably not yet been realised in France; but one would have liked to know what Calmette thought of the theoretical aspects of the question, especially of the explanation of the protective action of coal-dust, worked out experimentally by Mavrogordato,¹ which is among the most pregnant of recent discoveries in pulmonary and general pathology.

The book is very well printed on several sorts of paper. References to the literature are given in the most convenient way at the foot of the page; there is no index. It can be heartily commended to anyone interested in the subject, who will find in it a great mass of information and clear-cut, interesting opinions.

THE SYMPATHETIC NERVOUS SYSTEM IN DISEASE.

By W. LANGDON BROWN, M.A., M.D., F.R.C.P.,
Physician with Charge of Out-patients, St. Bartholomew's Hospital, &c. London: Henry Frowde, and
Hodder and Stoughton. 1920. Pp. 161. 10s. 6d.

Dr. Langdon Brown's book is an amplification of his Croonian Lectures, which have already appeared in the columns of THE LANCET. In it less attention is paid to the morphological details of the system than to its clinical symptomatology, and less, again, to a complete résumé of every symptom imaginable than to its behaviour in a few large nosological groups—viz., affections of the endocrine glands, of the digestive and circulatory systems, and glycosuria. In this fashion the beginner obtains a better conception of its function, and learns

how to apply principles to other morbid conditions, the outcome of sympathetic disturbances.

The value of Dr. Langdon Brown's little volume consists as much in its suggestiveness as in the actual information it embodies. The chapter on the relation of the system to the endocrine glands contains much interesting clinical material in reference to so-called diabetes insipidus, and a suggestive hint on the pharmacological action of valerian, a drug which is persistently decried by that scorner of all drugs the pure psychotherapist. We wish that the author had devoted more space to the possible effect of psychogenic factors on the function of the sympathetic system, for he is fully alive to the importance of this, and, indeed, supplies various clinical instances. It is probable that the future will see more attention paid to the actual pathology and pathological physiology of sympathetic disturbances, and that their outcome in emotional symptoms will be approached, therapeutically, from below as well as from above.

MILITARY PSYCHIATRY IN PEACE AND WAR.

By C. STANFORD READ, M.D., Physician, Fisherton House Mental Hospital, Salisbury; late Major, R.A.M.C., Officer in Charge of "D" Block, Royal Victoria Hospital, Netley. London: H. K. Lewis and Co. 1920. With two charts. Pp. 168. 10s. 6d.

By being in charge of the well-known "D" block at Netley during much of the war Dr. Stanford Read enjoyed exceptional opportunities for the prosecution of statistical and other studies in connexion with war psychiatry, and these are embodied in an interesting manner in this monograph. It is based more particularly on the investigation of 3000 consecutive cases admitted during 1917. Without giving the complete table of classification the following percentages may be quoted: Dementia præcox, 20; manic-depressive insanity, 14.3; confusional states, 17.1; paranoia and varieties, 16.6; mental deficiency, 13; general paralysis, 4.7; alcoholic psychoses, 1.6; epileptic psychoses, 1.2. Dr. Stanford Read's general attitude is one of enthusiastic acceptance of a psychogenic origin for the majority of the psychoses. For him dementia præcox "results from a faulty adjustment of life's demands," and "disharmonies in sexual adaptations constitute themselves an integral part of the disorder"; the psychological basis of paranoiac states is "of a homosexual nature," and only thus can we understand why "the paranoic trend is so extremely common a reaction among the war psychoses"; the anxiety of manic-depressive cases is, in fact, fear of ungratified desire of a sexual nature; as for alcoholism, "there are good grounds for believing" that "unconscious homosexual activity is capable of stimulating the craving for alcohol." There is a frank tendency on the author's part to emphasise the psychical at the expense, we think, of the physical, even in regard to actual commotio cerebri and the toxæmias of various kinds, due in part, no doubt, to the line in which his own medical interests lay, and to the atmosphere in which he found himself. If a patient has both malaria and a confusional state the psychologist, naturally, "spreads himself" on the latter; notwithstanding the intimate relation between emotions and internal secretions Dr. Stanford Read dismisses disturbances of the latter as of no ætiological importance.

We consider some of the most valuable work in the book is in connexion with the problems of the enlistment of the mentally unfit and of the improvement of the mental status of the soldier, and we welcome the sane and practical conclusions of the author thereon. His commonsense attitude is excellently expressed in the following quotation: "If means were taken that soldiers could more freely vent grievances and feel that sympathy and understanding were given them, if personal worries could be aired and advice sought, and if as little as possible any rankling sense of injustice were allowed to exist by a deeper study of those who come in conflict with disciplinary law, many a mental disorder might be nipped in the bud." The volume concludes with a cogent plea for adequate instruction in practical psychology as a part of the medical curriculum.

BODILY CHANGES IN PAIN, HUNGER, FEAR, AND RAGE.

An Account of Recent Researches into the Function of Emotional Excitement. By WALTER B. CANNON, M.D., B.C., Professor of Physiology in Harvard University. London and New York: D. Appleton and Co. 1920. Pp. 311. 15s.

THE physiologist has begun to tackle the problem of the emotions seriously and patiently. He, of all scientific workers, is most likely to be content with nothing less than experimental exactitude, and his interpretation of results is worth as much consideration as that of the psychologist. Everyone knows it is a long step from the neuronal simplicity of the dog to the complexity of man, but the applicability of data obtained in the laboratory to man is not thereby negated. Professor Cannon's general thesis, amply sustained by experiment, is that in pain and other emotional excitement certain reflex bodily responses occur which are to be regarded as anticipatory of the instinctive acts that naturally follow. Further, a mechanism exists whereby the changes initiated in an anticipatory manner by emotional excitement are continued or augmented by the emotion itself. By way of illustration it may be stated that certain alimentary processes cease and energy-supply for other parts is set free; blood is shifted from the abdominal organs to those immediately essential to muscular exertion (lungs, heart, central nervous system); energy-giving sugar in the circulation is mobilised—and all of these visceral changes are directly serviceable in making the organism more effective in the violent display of energy which fear, or rage, or pain may involve. Thus these dominant emotions are expressed in activity of the sympathetic system, but the visceral changes are more or less alike, though the emotions giving rise to them are different. Now if anger, terror, pain, anxiety, joy, grief, or deep disgust have as accompaniment acceleration of the heart, inhibition of stomach and intestinal movement, contraction of blood-vessels, liberation of sugar, &c., it follows, in the author's opinion, that the James theory of the emotions cannot be maintained, for the subjective quality of the emotions undoubtedly varies, yet the visceral responses are more or less uniform. The suggestion is that the visceral changes contribute to the emotional complex, but do not constitute it, and that, with the possible exception of anger, emotions cannot be expressed, and, presumably, felt, without the aid of the cerebral hemispheres.

DIATHERMY.

By CLAUDE SABERTON, M.D. London: Cassell and Co. 1920. Pp. 138. 7s. 6d.

THIS book is divided into three parts. The first part commences with a short historical account of the evolution of diathermy. The principles on which high-frequency currents are obtained are then explained, and various models of diathermy apparatus and methods of applying the current to the body are described. The second part deals with the medical uses of diathermy. The diseases and symptoms for which this form of treatment is recommended are next considered, and the methods of its application discussed for diseases of the circulatory and nervous systems, fibrositis, scars and adhesions, and diseases of joints; and some notes are added on its use in cases of pulmonary tuberculosis, pleural effusion, and certain other affections. The third part of the book deals with the surgical uses of diathermy; the principles of the method are described and its advantages indicated. Mr. Herbert Frankling, of Harrogate, has added a description of his method of performing cauterisation, by diathermy, of papillomata of the bladder by the suprapubic route, and of carcinoma of the tongue.

This is the first inclusive work on diathermy by an English author. Dr. Saberton gives his own experience and refers to the work of several authors, quoting freely from the writings of others. The book will be read with interest by those who are experienced in treatment by diathermy, and will be of considerable use to

others who are anxious to know more of the subject. The addition of diagrams would have assisted beginners to understand the complex diathermy machine, and the factors determining the depth to which coagulation extends in various tissues might with advantage have been more fully discussed. There are a few trivial slips; on p. 2, "Wertheim, Salomanson" should be "Wertheim Salomonson"; on p. 29 units of heat are given in "litres"; but the book is clearly written and well prepared, and there is a full bibliography.

GENITO-URINARY DISEASES.

Transactions of the Section on Genito-Urinary Diseases of the American Medical Association at the Sixty-seventh Annual Session, June, 1916. Chicago: American Medical Association Press. 1916. Pp. 350.

THIS volume consists of a collection of papers read before the American Medical Association. Each paper contains a report of original work carried out by the writer; many of these also have appended verbatim reports of the discussions which followed the reading of the paper. The papers are of interest in that they deal with the difficulties met with in the treatment and diagnosis of genito-urinary diseases. One of the more important of them emphasises the value of the Gradwohl test in the diagnosis of syphilis, comparing its accuracy with that of the Wassermann test; in the subsequent discussion it appears that all observers hold the view that it is the best test at present available. The post-operative complications of prostatectomy are gone into in several papers, and it is interesting to note that a number of operators are averse from the use of irrigation after the operation. The idea of collecting papers in this way is one which should be imitated.

LES INFECTIONS GANGRÉNEUSES DES MEMBRES CONSÉCUTIVES AUX PLAIES DE GUERRE.

By G. LARDENNOIS and J. BAUMEL. Paris: Masson et Cie. 1920. Pp. 248. Fr. 12.

THE first few pages of the book are devoted to a brief historical account of the subject; then follow sections dealing with the ætiology, pathology, symptomatology, diagnosis, prognosis, and treatment of gas gangrene. The last 20 pages contain a valuable bibliography, wherein references to many of the more important publications on gas gangrene may be found. The section on ætiology contains a brief but accurate description of the *Vibrio septique*, *B. perfringens*, *B. œdematiens*, *B. bellonensis*, and *B. sporogenes*. The importance of mixed infections with other organisms, especially streptococci, is duly emphasised. The various factors predisposing to gas gangrene are also considered. In the section on symptomatology, certainly one of the best in the book, a good description is given of the initial signs and symptoms of gas gangrene, and the value of early diagnosis, followed by immediate treatment, is pointed out. The authors recognise the following types of gas gangrene: Gas gangrene proper, localised or spreading; toxic types accompanied by great swelling of the muscles or extensive œdema; and gaseous phlegmons, localised or diffuse.

Treatment is considered under two headings: preventive and curative. Under the first the authors pass in review the various ways in which wounds have been dealt with during the war. The description given is rather sketchy, and those methods which were discarded after a brief period of popularity could easily have been left out. Removal of the projectile and other foreign bodies and complete and methodical excision of the wound, followed by suture in suitable cases, is rightly recommended as the best way of avoiding gas gangrene. Excision of the infected area or amputation of the limb is the treatment advised for cases of established gangrene. A good account of the use of vaccines and specific sera is also given.

The book is mainly the outcome of the personal experience of the authors, but the work of others has also been freely drawn upon. It is to be welcomed as a useful addition to the literature of the subject.

HANDBOOK OF DISEASES OF THE NOSE, THROAT, AND EAR.

For Students and Practitioners. By W. S. SYME, M.D., F.R.F.P. & S.G., F.R.S.E., Surgeon to the Ear, Nose, and Throat Hospital, Glasgow; Extra-academical Lecturer on Diseases of the Throat and Nose, Glasgow University. Edinburgh: E. and S. Livingstone. 1920. Pp. 329. 9s.

THIS is an attempt to compress an adequate description of diseases of the nose, throat, and ear into a very small compass, and it is not particularly successful. The teaching is perfectly sound and shows evidence of wide clinical experience, but it does not afford the complete and concise statements which are required by the student for examination purposes; nor, on the other hand, does it give those hints and details of treatment which would be helpful to the practitioner. Thus, as one instance out of many, the article on epistaxis will not suffice for the student faced with a question on its causation, and will not be a guide to the doctor who has to treat the affection. The illustrations are few and not very helpful. In any subsequent edition Dr. Syme will be well advised to leave out altogether the perfunctory mention of rare affections to make room for fuller treatment of common diseases.

MICROSCOPY.

Third edition. By E. J. SPITTA. London: John Murray. 1920. Pp. 534. 25s.

OF the common instruments of medicine the microscope is perhaps the one least generally understood and most often wrongly used. The general tendency of students is to try to obtain the largest magnification of an image possible with the objectives and eye-pieces available. They seldom use the instrument in order to gain the maximum knowledge of the object studied, and even qualified medical men do not always use their microscopes intelligently. "Microscopy" teaches in simple language and with the aid of large numbers of diagrams and photographs the elementary laws of optics and the principles of instrument construction, and shows very clearly the limitations of the microscope as well as the methods by which the best possible image may be obtained. The book is not written for medical men alone, but it will be especially valuable to them. The third edition is revised and considerably enlarged. New sections of special interest are added, notably on the use of combinations specially designed for the study of large objects at low magnifications. The later developments of microscopy—for example, the use of short wave-length films for improving the resolving power of objectives of large numerical aperture—are not neglected.

The book is well produced, the plates being especially beautiful.

ERGEBNISSE DER GESAMTEN MEDIZIN.

By Professor Dr. TH. BRUGSCH. Erster Band. Berlin and Vienna: Urban and Schwarzenberg. 1920. Pp. 657+vi. M.180.

THE aim of this book is to provide a summary of the advances which take place in medicine year by year. The first volume covers a wide range of subjects, including gynaecology, radiology, nervous diseases, acute fevers, tropical diseases, and so forth. There are 25 chapters, each being a short monograph on the subject under discussion. The book differs from our *Medical Annual* in that no attempt is made to summarise all the important work of the year. It is not clear what system has been followed in the choice of the subjects. Infective diseases receive a generous share, respiratory diseases a very poor one. It is clear, however, that even a volume of more than 600 pages cannot contain all the new work in the whole realm of medicine, unless it be rigorously edited. The editing is, however, uneven. Some chapters contain a list of references to German work only; others give a more cosmopolitan list of French, English, and American publications, whilst in some instances—for example, the omission of Besredka's work in the chapter on Anaphylaxis—the

absence of a bibliography gravely reduces the practical value of the book. Inability to obtain access to recent foreign work may be responsible for this apparent neglect.

It is manifestly impossible to review adequately a book dealing with such diverse material. Of the diseases to which the war has attracted interest, typhus fever receives a comprehensive monograph, with a page and a half of references; "five-day fever," which has figured so largely in German medical literature during the war, is dealt with, and the chapters on protozoal diseases discuss amoebæ, hæmorrhagic jaundice, and diseases of the intestine. There is also a lengthy review of the sunlight treatment of surgical tuberculosis, with numerous illustrations. The book is unbound and contains no subject index.

BACKWATERS OF LETHE.

By E. A. H. BARTON. London: H. K. Lewis and Co. 1920. Pp. 151. 5s.

THE serious student need not be alarmed by the unconventional title of this book and of some of its chapters, as the contents are for the most part orthodox. Dr. Barton has rescued from the stream of oblivion many things worth remembering by those who give anæsthetics. Under the title of "Arma Virumque Cano," he discusses the anæsthetist's qualifications and apparatus, while "shoals and rapids" covers a useful discussion of common difficulties and dangers. Good examples are given to illustrate the danger of too light and too deep narcotisation with chloroform. The author's favourite method is a succession of C.E., ethyl chloride, and ether carried out by means of an open mask and the inhaler of his own design, which includes a face-piece and circular metal pillar. With this apparatus Dr. Barton gives "open" ether, but the effects must surely differ in degree from those obtained with a perfectly open mask and a drop-bottle. Dr. Barton recommends morphine with atropine before ether and uses it more freely than do some of his colleagues. The author is evidently both enthusiastic and critical, and has collected in this book a number of wise judgments and opinions resulting from his extensive experience in a branch of practice to which too little attention has hitherto been given.

FOOD POISONING AND FOOD INFECTION.

By WILLIAM G. SAVAGE, B.Sc., M.D. Lond., D.P.H. Cambridge University Press. 1920. Pp. 247. 15s.

Dr. Savage does well to point out that few subjects are so often treated in text-books, both in a hackneyed and in an inaccurate fashion as food poisoning and food infections. The title "ptomaine poisoning" is still retained in some quarters years after it had been proved that it is both incorrect and misleading. The question was well summed up in a report to the Local Government Board for which Dr. Savage was chiefly responsible in 1913, when the medical officer of the Board, Sir Arthur Newsholme, wrote that the cases commonly known as "ptomaine poisoning" (products of food decomposition) are generally recognised to result from the presence in the food materials consumed of certain pathogenic organisms, which are either living and capable of active multiplication or which, although affected by the cooking, are, nevertheless, poisonous by means of the toxins contained in them. The term "bacterial food poisoning" thus came into being as more correctly describing this group of diseases. The public health services will heartily welcome this book, for, though a comparatively small volume, the author has included most, if not all, known causes of food poisoning. There are chapters dealing with chemical poisons in food, preservatives, foods inherently poisonous, food idiosyncrasy, and so forth. The book clears up many of the obscurities which have surrounded the subject, and a valuable sequel to Dr. Savage's careful studies will be found in the chapter on the prevention of food-poisoning outbreaks, and in the final chapter on methods of investigating such outbreaks. We have here a valuable adjuvant to public health administration.

THE LANCET.

LONDON: SATURDAY, JULY 10, 1920.

Medical Education and the Preliminary Sciences.

AT few, if any, of the Sections at the recent meeting of the British Medical Association was more important business transacted than at the Section of Medical Education. For, while in every other Section recent medical advances were being discussed along various divisions of our comprehensive work, and especially such advances as would prevent early disease in the community, in the Section of Education there was under debate how the class of men to carry on these large and responsible public tasks could best be educated. Professional knowledge serves little unless it can be transmitted to those who are to give practical effect to it. Sir CLIFFORD ALLBUTT, President of the Association, and Sir GEORGE NEWMAN, President of the Section of Education, alike indicated that the medical curriculum must be open to recurring revision, because on its scientific side we are dealing with ever progressive acquisitions of knowledge, while the environment in which this knowledge has to be applied is also ever changing, and particularly is changing in directions that must tend to make the activities of medicine more directly applicable to life at large. Such propositions are recognised as a commonplace by all society, while the fact that the existing medical curriculum in this country is without certain qualities necessary to train students to the best advantage is equally a commonplace with those who have studied the subject.

With this accepted information before them, and before their audience, five distinguished men delivered important speeches to the Section, and the substance of what they said will be found in our columns, while their full papers have been published in the Journal of the British Medical Association. The speeches of those who opened the discussion, as well as of those who joined in it, assumed that the revision of the medical curriculum, which is actually promised for an early date by the General Medical Council, will not lead to any time-extension of the course. But much pressure is being put, and legitimately put, upon the General Medical Council to give expression in the training of medical students to scientific and professional features which have hitherto been ignored, so that the dilemma is reached that, while by general consent the curriculum cannot be lengthened, many consider that it should include methods and directions of instruction which are now absent from it. It follows that the curriculum must be lightened at either end or both ends, so that the years spent in the medical school proper and in the wards, where the professional subjects, scientific and clinical, and the course of actual disease as it occurs in bulk, are studied, may not be trespassed upon either by the belated attention to the ancillary sciences or by the unnecessary intrusion of specialism. The tenour of the debate before the Section of Education revealed no dissent from the view that the professional period of medical study must be as uncomplicated as possible, if the medical student is to cover the course and obtain qualifications in

any time like five years. The different speakers directed themselves towards explaining what they considered should be the relation of the sciences of chemistry, physics, and biology to the after events of the medical curriculum, in order that this preliminary scientific education, instead of being the industrious or idle cram that it often has been, should become the basis of the student's thoughts; so that throughout the study of the professional subjects scientific accomplishment and bias should assist the student at every turn in his acquisition of pathology and technique. From their words the ideal of early training in science emerged: namely, that it should be clear—and this postulates the good general education of the recipient—practically interesting, and formative. It should not lead to the detailing for examinations of so many boys in so many months knowing so many things in accordance with a syllabus; it should mean the sound preparation, by intelligent instruction in the essentials, of students who will be able to use what they have learned generally, in its special applications to all that may follow. Thus the philosophical conception of the pure sciences will arrive, and will be infused in the pathological work, giving intensive meaning to that work while also clarifying it.

It is clear that if the curriculum is to be strengthened without being lengthened, and simplified without being lowered in standard, the whole of the five years required by the State from the student must be used with the greatest economy. Having always in our eye the average student, we must admit that this can only be done if these five years are kept as clear as possible from the invasions of the unnecessary, while the students themselves must be sufficiently well educated to take full advantage of the opportunities for learning what is necessary. Their own time and the time of their teachers must not be wasted by finding in every class lads whose equipment does not fit them to understand the necessary courses of instruction. Every medical student to-day requires a good general preliminary education, and it is what a great many do not receive. Here is one definite thing which those who revise the curriculum must see to, for until this first impediment is removed early instruction in science is unduly hard, both for the pupils and the masters. If the students could come to their medical studies proper, whether at the medical school or under a University faculty, ready to attack anatomy and physiology, and having behind them an adequate training in chemistry, physics, and biology, the work to be done in the statutory five years would be enormously lightened. Can this substantial alteration in the curriculum, which has been proposed in different shapes for many years, be justified, implying, as it does, the use of the last year of schoolboy life, and perhaps even of two years, in preparing for medical studies proper? The General Medical Council may be inclined to solve the embarrassment of the overloaded curriculum in this way, but the proceedings in the Section of Education showed that such a solution, while expected, will be attended with many complications. There is at present in existence no large number of schools where the student can acquire that really practical knowledge of chemistry and physics which later should inspire and foster the whole of his medical work, and this we hold strongly should occur; while in the case of biology it is admitted that adequate training is offered by hardly any of the secondary schools. A practical

beginning in the revision of the curriculum—the improvement of general education being taken for granted—would be to leave chemistry and physics as schoolboy subjects, retaining biology as part of the medical course proper; and it would be understood that the lessons learned by the schoolboy in physics and chemistry would be called upon, and his knowledge in these directions developed by continuation study in connexion with his professional subjects. The suggestion has this practical force behind it that chemistry and physics are the groundwork of all scientific education, and whatever the schoolboy who intends to make his career dependent upon scientific knowledge may elect to do, complete familiarity with these sciences will be required of him. Biology is to this extent different, that it forms a definite introduction to the pursuit of medicine. A resolution embodying this change in the curriculum was set down at the Section of Education, and will be brought to the notice of the Education Committee of the General Medical Council.

The Wassermann Reaction.

THE complement-fixation test in syphilis has proved, and is likely for some time to prove, of more far-reaching importance than its discoverers can have imagined. When WASSERMANN, NEISSER, and BRUCK in 1906 published the fact that the complement-fixation test could be applied in syphilis there was no reason why they should not have regarded it merely as a special application of the Bordet-Gengou reaction, in which complement was used up in the interaction of specific antigen with its specific antibody. From the standpoint of diagnosis in syphilis Wassermann's reaction has amply fulfilled the expectations of its originators. How accurate it has become in the hands of expert workers was shown in a recent Report issued by the Medical Research Council (Special Report Series, No. 21) recording an experimental trial, in which more than 100 sera from cases of known syphilitic or non-syphilitic nature were examined by three separate workers of repute, with results which were astonishing in their concordance with one another and with the known clinical facts. The test, as all our readers know, has become a routine part of diagnosis, and there is no need to enter here into any discussion of its merits from this point of view. The only doubtful questions concern the precise manner in which it is best carried out. But there is another and much wider aspect opened out by Wassermann's reaction, one that in the long run may, we think, prove of even greater importance than the mere diagnosis of a specific disease. The grounds on which WASSERMANN and his colleagues based their experiments were rigidly scientific. In accordance with the observations of BORDET and GENGOU, they deemed it necessary to use as antigen an extract of syphilitic liver, and they assumed that a positive reaction meant the presence of specific antibody in the blood of the patient. But it was soon found that the specific antigen was unnecessary. An alcoholic extract of normal liver or heart, even from a guinea-pig, was found to serve just as well, and, indeed, solutions of known chemical composition—e.g., of lecithin and cholesterol—were proved capable of acting as antigen, and this without any impairment of the diagnostic value of the test. We know of no other instance in which a reaction of this sort has suffered the wreck of its

assumed scientific basis and become a frankly empirical test without at the same time being proved invalid. It was not to be supposed that scientific men would tolerate such a shock to their principles, and it became necessary to search for other scientific grounds on which to base an explanation of the phenomenon. The bio-chemists have been at work, and for the first time in the history of immunology it seems possible that an intimate serological problem may ultimately receive a physico-chemical explanation. We are, doubtless, a long way from this at present, but much has been already accomplished, and if study of the Wassermann reaction should lead to so happy a result the test will acquire a significance far transcending that of its diagnostic value.

We have been prompted to these remarks by the receipt from the Ministry of Health of a Report on the Complement-fixation Test in Syphilis,¹ which merits the careful attention of those of our readers who are interested in the scientific side of serological problems. From the nature of the subject it is not light reading; much of it, indeed, is difficult reading, save for the expert, and we doubt not it was difficult writing. But it contains a large amount of patient and valuable research and of deep and original criticism. In a short introduction Colonel L. W. HARRISON explains the origin of the work contained in the Report. It was a scheme, interrupted by the war, for a prolonged research into the properties of the various ingredients in the Wassermann test in order to improve, if possible, the technique of the reaction. The work has been carried out by Dr. F. GRIFFITH and Dr. W. M. SCOTT at the laboratories of the Ministry of Health, under the general superintendence and advice of Colonel HARRISON. It has been proceeding since July, 1917, and the Report by Dr. GRIFFITH and Dr. SCOTT contains a mass of valuable observations which, in their opinion, suggest certain improvements in the method of carrying out the Wassermann test. As everyone is aware, most persons react to the test in a frankly positive or negative manner which admits of no cavil. The difficulties arise in the so-called border-line cases, in which the reaction is a weak one. There is in normal sera a small but variable amount of the substance, or property, which reacts with the antigen, and the problem is so to balance the ingredients in the test as to exclude these, while making the test sufficiently delicate to detect real syphilitics. This cannot, of course, be done absolutely, but all techniques have as their aim as close an approach to this ideal as can be achieved. As a result of their work Dr. GRIFFITH and Dr. SCOTT put forward a technique, which is supported in detail by their experiments, and of which the two chief principles are: (1) A very highly diluted antigen, consisting of the acetone-insoluble fraction of the organ-lipoids dissolved in alcohol, to which is added a suitable dose of cholesterol; for use, the alcoholic solution is rapidly diluted with normal saline to 1 in 640. (2) The second principle consists in prolonged fixation in the ice chest for 18 hours, instead of at room temperature or 37° C. This is an application of the observations of DEAN and of SMITH and MACNEAL. A further principle adopted is that of maximum sensitisation of the corpuscles, with only a moderate dose of complement, which is kept constant. The method

¹ Reports on Public Health and Medical Subjects. No. 1. 1920. Price 5s.

is favourably reviewed by Colonel HARRISON in his introduction, but space forbids our entering into further discussion of it here. The remaining and longer portion of the Report is occupied by a critical review of the principles involved in the Wassermann test by Dr. ARTHUR EASTWOOD. Only those who have attempted to grapple with the vast literature which has sprung up on this subject, and know its highly technical and controversial nature, can appreciate what Dr. EASTWOOD has done in preparing this review, which is probably the most impartial, as it is the most complete, in the English language. It is divided into two parts, the first dealing with "Complement," and the second with the so-called "Wassermann Substance." The writer does not attempt to put forward any theories of his own; his work lies in a candid statement of the various points at issue, with the answers propounded by the different workers who have written about them, the evidence being given in each instance and its validity critically considered. At the present day no final answers are possible, and the method adopted by Dr. EASTWOOD is clearly the best and most useful which he could have chosen. All serological workers will owe him a debt of gratitude for the conscientious way in which he has performed a laborious task, and for the critical acumen which he has brought to bear upon it. Anyone who is in search of a subject for original research will find abundant suggestions here.

We should like to be allowed, in conclusion, to congratulate the Ministry of Health on this the first report of the kind which it has issued, and to express the hope that it may be succeeded by many others of equal value and importance. Work on such lines is precisely that which can best be carried out in the laboratories of a Government institution. We noted the other day in the public press a singularly ill-informed outcry of "waste," because Reports on the Wassermann test had been published by two separate Government departments. The particular piece of research recorded in the present Report was not only carried out, as will be understood from Colonel HARRISON'S introduction, with the full knowledge of the Medical Research Council, but was designed to fill certain gaps in knowledge which the Reports of that Council had emphasised. It was evidently carried out in the laboratories of the Ministry of Health because it could be done better and more economically there than elsewhere.

The Position of General Practice.

Dr. PETER MACDONALD, of York, described the debate on the future of medical practice, held by the British Medical Association at Cambridge on Friday of last week, as one of the most valuable ever instituted by any medical body. Probably it was one of the most enlightening. For no doubt many general practitioners came to it with grave misgiving as to the part which the State is preparing to take in moulding the outward form and conditions of medical practice, and were reassured by the emphatic utterance of the Chief Medical Officer of the Ministry of Health, "Nationalisation of the medical profession—it simply cannot be done." Sir GEORGE NEWMAN went on to speak of the action of the State in continuing to pile up duties—under Public Health, Education, Mental Deficiency, Children, Midwives, and other Acts—on

a doctor who can never be organised in any strict sense, on a profession the whole genius of which is individualistic. Although safeguarding his Department by assuring his audience that he was speaking wholly in an unofficial capacity, it yet seems quite clear that so long as Sir GEORGE NEWMAN is principal medical adviser to the Ministry of Health and to the Board of Education nothing will be done to abolish the personal relations now existing between the general practitioner and his patient. Behind these relations lie a long history and sound reason.

But some change there must be, for it is clear that the two contracting parties, the State and the medical profession, cannot be allowed to drift into a position of misunderstanding. The State has become conscious, as never before, of the community's need of the medical profession, and the medical profession is aware of new obligations, not merely those imposed by statute, but others, the result of social and economic factors hitherto regarded as scarcely coming within the range of medicine. Adjustments are needed, and in many ways a closer relation between the State and the general practitioner, who should maintain nevertheless all that is of permanent value in his relation to his patient. Dr. ALFRED LINNELL, speaking in the discussion from the standpoint of that most general of all general practitioners, the man in rural practice, regarded the primary health centre as the pivot around which the new medicine is to turn. Provided with greater facilities to study and find out the beginnings of disease, and to treat them efficiently when discovered, and paid well enough so as to have no need to rush his work, the general practitioner in these circumstances will remain not only the essential humaniser in medicine, but, as he already is, the chief agent of preventive medicine. The growing disposition at the Ministry of Health to take the general practitioner by the hand and help him in his work was acknowledged in the discussion.

The debate was necessarily scrappy. Five medical men, moving in five distinguished spheres of medical endeavour, were prepared with addresses, each on a special aspect of the subject, and each contributor was heavily weighted with new thoughts and ideas. Sir GEORGE NEWMAN spoke for the State, Sir WILMOT HERRINGHAM for the consultant, Dr. LINNELL for the rural practitioner, Professor F. GOWLAND HOPKINS for medical research, Mr. E. W. MORRIS for the hospitals from their institutional aspect. It would take much ingenuity to dovetail all that was said into a workable scheme. But none of the speakers had any thought of abolishing general practice or of altering in any essential way the relation of practitioner to patient. Only Mr. Alderman JENKINS, the Secretary to the Health Committee of the Labour Party, spoke of a State service, but then in the same breath he indicated that he did not desire to see medical men "civil servants in the sense in which we think of them." The medical service which he had in mind would study the conditions under which workers live and work, and would educate them in the safeguarding of their health. That is what we should all like to see. The outstanding message of this debate is that general practice, extended and sublimated, remains for our generation upon its long-tried and noble plan; it remains as a career for the brightest and best of students to enter.

Annotations.

"Ne quid nimis."

INTERNATIONAL PUBLIC HEALTH.

THE Medical Advisory Board of the League of Red Cross Societies is holding its first meeting at Geneva this week. We enumerated its 15 members in our issue of June 5th and need only repeat here that the representatives from this country are Colonel S. Lyle Cummins, Sir Walter Fletcher, and Sir George Newman, and that the other delegates are equally distinguished. The public health problems of Asia and Africa have heretofore often appeared immense and baffling; it is now the health of Europe which is the white man's most pressing burden, and the attention of a continent will be concentrated on the deliberations going on by the side of Lac Léman. The opportune moment has been utilised for the appearance of the first number of the *International Journal of Public Health*, published bi-monthly by the League in four editions—English, French, Italian, and Spanish. Dr. Thomas R. Brown is the editor, with a staff of one associate and six assistant editors under him. The first three numbers are to be issued gratis in all parts of the world, and with the fourth issue in January, 1921, a subscription rate of 20s., or its equivalent of 5 dollars, 25 francs or lire, will be instituted. The scope of the journal is apparent when it is noted that this pioneer number includes as its first original article an essay by Professor A. Calmette on the protection of mankind against tuberculosis, part of a report by Dr. Richard P. Strong on the antityphus campaign in its bearing on Poland, and a sketch by Dr. George C. Whipple of the possibilities of world sanitation in the twentieth century. The contributions contain brave words which need bold administrators to carry them out.

THE MENTALITY OF JUVENILE ADULT DELINQUENTS.

THE problem of the connexion between criminality and mental deficiency bristles with difficulties whatever be the aspect, social, legal, or medical, from which it is approached. Reports, both of expert individuals and of commissions appointed to deal with the subject, are at the disposal of those who seek general principles for application in practice, but no definite body of doctrine is yet available nor is likely to be until more data have been collected. The general trend of opinion to-day is setting towards the indispensability of psycho-physical examination of each individual delinquent, an attitude preferable to any sentimentality or unthinking humanitarianism on the one hand, or to the unvarying application of an inelastic legal "yes-or-no" criterion of insanity or mental deficiency on the other. The youthful offender may look like an angel and act like a demon, but neither looks nor acts suffice for a diagnosis. In the case of the adult, pilfering or thieving may be the expression of definite organic conditions, such as early general paralysis, alcoholism, or morphinism, as well as the outcome of moral or mental deficiency unaccompanied by any obvious structural or toxic change; there is evidence to suggest that in the case of women kleptomaniac outbreaks are frequently associated with the menstrual or premenstrual period, and Glueck has recorded a case in a male where theft seemed to be a form of perverse sexual gratification. Persistent lying, similarly, in the form of pseudologia fantastica, may be a symptom of actual cerebral disorder, no less than one of the phenomena by which the criminal evidences his antisocial outlook.

If, then, it is granted that individual symptoms customarily regarded as of a pronounced antisocial cast may be ascribed on occasion to structural or toxic disease, we are bound in any assessment of criminality to take cognisance of the subject's physical and psychical make-up, a matter not to be decided by a brief interview with the criminal, but necessitating a prolonged, tedious, and painstaking investigation. To assign criminal traits to heredity or to

environment is too ready-made a solution to be of value. Dr. John M. Ahern, medical officer to the Borstal Institution, records elsewhere in this issue the results of an inquiry into the mentality of the inmates of that reformatory, conducted during February and March of this year, an inquiry of the kind which is essential if any progress is to be made. Only some 10 per cent. of the 928 juvenile adult delinquents came under the category of the mental defective, though Dr. Ahern considers this a very conservative estimate, ignoring as it does borderline cases and slighter yet unmistakable degrees of mental deficiency. Intellectual defect is probably of least significance in connexion with the criminal propensities of the subject; degree of criminality and level of intellectual attainment show no correspondence, for the village idiot, Dr. Ahern reminds us, may be amiable and inoffensive. It is a nice point, however, whether intelligence and intellectual attainment are strictly synonymous. The actions of many criminals show a high order of cleverness yet but a low order of intelligence, for the latter connotes the ability to apply knowledge and to profit in the school of experience. Now Dr. Ahern makes the shrewd observation that continued misconduct, if it be of a purposeless character, is always suggestive of mental defect; the habitual offender is dull to his own interests, however brilliant a rebel he may fancy himself; he has not the wit to appreciate the strong inducements to good conduct that are to be found in a Borstal institution. The same is true, doubtless, of the adult criminal; a career of crime implies inability to realise the inevitable consequences.

It is difficult, in a way, to separate the emotional from the intellectual factor in mental defect associated with criminal tendencies, since emotional outbursts may have their origin, as Dr. Ahern says, in some idea of "getting one's own back." Unreasoning, meaningless, emotional overflow may fairly be regarded in some instances as an epileptic equivalent, and this is especially true of violent temper, which has been shown statistically to be frequent in epileptic families. In other cases the emotionally unstable are plausible, well-spoken, generous, and of good behaviour under rigid supervision, and there are great differences in the way in which the defect is manifested, with corresponding difficulty when it comes to the question of certification. It might be supposed, legitimately enough, that the physiological disturbances of adolescence will account, in part at least, for the emotional instability of the youthful delinquent, and that with the establishment of neuro-glandular equilibrium emotional balance will likewise be attained, but too much reliance can be placed on this hope. Many criminals remain at the level of children as far as their affective life is concerned; they become the catspaws of stronger minds than their own. All observers are agreed on the seriousness of the problem presented by their treatment, institutional or otherwise. If their general level of intelligence is fair, as is often the case, it should be possible, in some instances, to strengthen control by suitable psychological re-education, and in others glandular therapy, where indicated, might well be given a trial. No line of therapeutic approach should be vetoed because of mere novelty or frank empiricism, as long, that is, as there is evidence of actual psycho-physical imperfection. In any case, the results obtained by the Borstal system indicate that for very many youthful criminals who are not too much below par mentally and physically the outlook is hopeful enough, provided medico-psychological investigation and treatment are given as ample chances as the nature of the human material demands.

MEDICAL SECRECY IN FRENCH LAW.

A CASE has just been heard on appeal in a French higher court which raised very pointedly some of the questions of professional secrecy so closely discussed at the Representative Meeting of the British Medical Association. The Eighth Chamber of the Paris Court of Appeal was asked to decide on the right to produce in court a confidential medical certificate.

A certain Monsieur X appealed for a divorce from his wife, producing in support of his action a doctor's certificate on which his lawyer laid great stress. The Court of Second Instance as well as that of First Instance decided to disregard this certificate, since professional secrecy did not allow a doctor, without the patient's knowledge and consent, to deliver a medical certificate to a third person, even should that person be her husband. The production of the certificate was held by the court to be a serious injury, and the suit was decided in the wife's favour. The decision confirms once again the legal position long ruling in France. For a doctor to supply a certificate containing facts, of which he has only come to a knowledge in professional circumstances, constitutes a lapse from the duty of discretion imposed upon him by law. No such certificate is admissible as evidence in a French court of law.

EPSOM COLLEGE.

Epsom College is passing through a period of financial stress which is a source of anxiety to its promoters and of obstruction to the smooth working of the institution. The annual report of the Council presented to the governors on June 25th shows a deficit of £4425 incurred during the year 1919. This is accounted for mainly by the need for extensive repairs, which had accumulated during the war, by the higher salaries paid to masters and officials, and by increased establishment and catering charges. Some of the additional expenses will be met in the future out of increased school fees payable from next September. Sons of medical men will then have to pay 100 guineas, others 120 guineas, and day boys 40 guineas, against the former charges of 70, 80, and 25 guineas. The sum of £6000 will shortly have to be repaid to the mortgagees, while interest on the remaining £8000 of the mortgage must be raised from 4½ to 5 per cent. In view of all these facts the Council has decided to create mortgage debenture bonds of £100 each on the security of the College lands and buildings, in order to pay off both mortgage and banker's loan. Friends of the College are asked to take up these bonds. The double purpose of assisting in the provision of a public school education to sons of medical men at reduced fees, and of affording financial support to necessitous doctors, their widows and families, should commend itself to all members of the profession. The war record of old Epsomians and masters—to be memorialised in a reconstructed nave to the chapel, for which the fund is not yet closed—is sufficiently distinguished to add to the school's claim for turning out the right sort of men, and its present needs appear modest enough to command a speedy release from embarrassment.

THE TREATMENT OF ACUTE INFECTION OF THE KNEE-JOINT BY ACTIVE MOVEMENT.

"Everything that is universally accepted as true in surgery is invariably false." These are not, as might be supposed, the words of one of the caustic critics of our art, whom, from Molière to Bernard Shaw, we have always with us, but of one of its greatest exponents. They refer to the accepted treatment of tuberculous, rheumatoid, and other forms of arthritis by rest, which Sir W. Arbuthnot Lane stated recently in our columns¹ can often be benefited by allowing active movement, if sufficient extension can be exerted to take pressure off the opposing articular surfaces. During the war a Belgian surgeon, Dr. C. Willems, Director of the Hoogstade Military Hospital, had the courage to go even further and treat acute arthritis, principally of the knee, due to infected bullet wounds, by incision and drainage, followed by immediate active movement. The movement expelled pus and prevented adhesions, and the results were excellent. In the *Boston Medical and Surgical Journal* Dr. F. B. Lund has reported the following case treated by this method. A man, aged 43 years, received a bullet wound in the right popliteal space on Dec. 7th, 1919. The X rays showed

a flattened bullet in the back of the knee-joint. On Dec. 11th the temperature was 100° F., the skin was reddened, and there was evidence of fluid in the knee-joint. On the 12th a 1½-inch incision was made on either side of the patella, and a large amount of sero-purulent fluid escaped. A 3-inch incision was made in the middle of the popliteal space, and the dissection carried down to the inner side of the popliteal vessels. After considerable difficulty the bullet was found in the capsular ligament projecting into the knee-joint. A rubber tissue drain was placed in the popliteal space and a dry dressing applied. Active movement was begun next day. The patient coöperated very well and was proud of the amount of movement of his damaged leg. The movement was regularly continued daily, the temperature rising gradually until on Jan. 3rd a collection of pus in the upper part of the popliteal incision was drained by insertion of forceps and a rubber tube was inserted. On Jan. 9th another pocket of pus was opened. At this time active movement was not so free as it had been on account of swelling and tenderness in the popliteal space. The Carrel-Dakin treatment was then adopted and the amount of pus diminished. Active movement was continued, but not to the same extent, and on April 1st he was up on crutches with 45° of flexion and perfect extension. He was discharged with perfect movement of the joint. Of the value of the active movement there could be no doubt, though recovery was delayed by the complication of abscess in the popliteal space. Considering the permanent stiffness of the knee-joint which usually follows suppuration the recovery was remarkable. In the *Annals of Surgery* for September, 1919, McWilliams and Hetzel state that in 73 cases of war wounds of the knee-joint 16 became infected. Of 12 of these, in which the final result is known, amputation was performed in 3, resection in 1, 4 resulted in ankylosis, and 4 were fatal. These cases were treated by the old methods. The writers believe that the treatment of Willems would have given much better results. In 100 cases, of which 18 were accompanied by purulent synovitis of a virulent type, chiefly streptococcal, he had no deaths and no amputations. There was 1 resection and only 2 stiff joints.

FINANCIAL DIFFICULTIES OF IRISH HOSPITALS.

In our last issue reference was made to the serious financial position of the Royal Victoria Hospital, Belfast. Our Irish correspondent now writes: I am glad to be able to state that on July 1st at a meeting of the Working Men's Committee held in that institution it was decided that as 1d. weekly was no longer an adequate contribution from the employees the amount in future should be at least 2d. a week from men and 1d. from women, girls, and boys. It was also passed to ask employers to deduct workers' subscriptions from their wages. It remains for the employers now to follow the example set by their workers. At present interest from investments supported 56 beds; general subscriptions from manufacturers, the Hospital Saturday collections and charitable donations maintained 65 beds; and the working classes' subscriptions 96 beds. The latter had increased from £5076 in 1915 to £12,500 in 1919, and it is needed that they should further grow to £20,000. The total cost of the institution had increased from £14,741 in 1914 to £38,409 last year, the principal items being: dietary, £5000 to £14,000; nurses' salaries, £13,038 to £24,078; ordinary salaries, £2014 to £4060; medical and surgical requisitions, £2400 to £4844. The extra wards brought into use during the war now cost an additional £12,000 a year. The Maternity Hospital, Belfast, the main training institution in that city for students and midwives, is also experiencing financial difficulties, due to increased cost of almost everything. As, according to the estimate of the Ministry of Health, there should be one maternity bed per 2000 population, Belfast on this ratio should have 250 beds; it has, however, only 70; and if a line be drawn across Ireland from Dublin to Galway, Belfast is the only place north of this line that has any maternity institutions except in workhouses, some of which are admirable,

¹ THE LANCET, May 29th, p. 1159.

and are recognised both by the Central Midwives Board for Ireland and by the Queen's University of Belfast as places where both midwives and medical students may obtain practical training.

A report by Sir Francis Champneys just published, dealing with the answers received from a large number of medical schools on practical midwifery, and presented to the General Medical Council at its last sittings, runs thus: "The immediate provision of beds in sufficient number to supply the needs of our medical students is probably impossible. The utilisation of beds in Poor-law institutions might help." The Education Committee recommended that steps may be taken for the utilisation of existing Poor-law lying-in institutions for clinical instruction. This wise suggestion was adopted by the General Medical Council so far as England and Scotland were concerned, but was omitted in the case of Ireland; and now it is found such an omission would not be justified. Only this week, at the clinical practical examinations in midwifery of the Queen's University of Belfast, a large batch of students were examined at the very commodious Maternity Hospital of the Union Workhouse, Belfast; and without this place (owing to the large number of students for the M.B. Final Examination—66 in all) a number could not have been examined practically. The sooner omission of Ireland from the suitable recommendation of the Education Committee of the General Medical Council is abrogated the better in the interest of both medical students and midwives. It is all very fine to talk of the stigma of Poor-law institutions, but what is yet supplied to replace them? The unusual number of medical students and of pupil midwives must be provided with practical midwifery instruction in the present emergency, and, to do so, workhouse lying-in wards are urgently required in Ireland, and must be made available as in England and Scotland.

SOLUTIONS FOR INTRAVENOUS INJECTION.

THE Medical Research Council have arranged to place on the market sterilised solutions of gum acacia like those extensively used in military hospitals during the war in the treatment of hæmorrhage and shock. It is believed that the experience of the war will have created a demand for these solutions for the purposes of civil surgery, but that many hospitals have been unable to undertake the manufacture of the solutions in their own laboratories. The solutions are made according to the method employed during the war at the Base Hygiene Laboratory, B.E.F., as described in the Medical Research Council's Special Report, No. 25. They are made up in special stoppered bottles containing 500 c.cm., and are sold at the price of 1s. 6d. per bottle, plus a charge for transport; 6d. is also charged for each bottle not returned when empty. All inquiries should be addressed to Messrs. Evans, Sons, Lescher and Webb, Ltd., at the Bacteriological Research Laboratories, Runcorn.

MYCOTIC OTITIS.

ACCORDING to Dr. C. J. Koenig,¹ oto-rhino-laryngologist to the American Hospital of Paris, mycotic otitis, though well known, is not of very frequent occurrence. He records a case in a woman, aged 27, with cicatrised pulmonary lesions supposed to be of tuberculous origin, who had been treated for eczema of the right external auditory meatus, followed by tinnitus, itching, and deafness. On inspection the meatus was found to be full of greyish masses of what appeared to be macerated epithelial debris, on removal of which the drum was seen to be perforated at its antero-inferior segment. After treatment by catheterisation of the Eustachian tube, syringing the meatus, and instillation of alcohol and peroxide, the perforation closed, the canal became normal, and the hearing returned. As the symptoms recurred within a few weeks on two subsequent occasions the greyish masses which had been taken for macerated epithelium were examined

and found to be intricate meshes of mycelium containing spores. Cultures of the ear on Sabouraud's medium showed a typical growth of *Aspergillus niger*, which of all inferior moulds is the one which develops most frequently in the external auditory meatus. Dr. Koenig suggests that the previous affection of the lung was not due to tuberculosis, as had been supposed, but to aspergillosis, inasmuch as pulmonary mycosis is apt to simulate tuberculosis, and the sputum in such cases shows acid-fast bacillary forms resembling Koch's bacilli.

EMERGENCY DISTRIBUTION TO LONDON HOSPITALS.

THE Hospital Fund for London, associated with the name of King Edward, has just distributed £250,000 to meet the immediate and pressing needs of the London hospitals. The grants are made with the express object of assisting the hospitals to carry on their work, and in the hope that where special difficulty is being found in raising funds for maintenance, the grant may afford the hospital authorities an opportunity of considering the best methods for improving their financial position. The grants are from £25 upwards, in accordance with the size of the hospitals and the special circumstances of their needs. Those of £1000 or over are as follow:—

Bolingbroke Hospital, £1500; Charing Cross Hospital, £2100; City of London Hospital for Diseases of the Chest (Victoria Park), £3000; Dreadnought Hospital, £1000; East London Hospital for Children, £3000; Elizabeth Garrett Anderson Hospital, £1250; Great Northern Central Hospital, £12,000; Guy's Hospital, £7000; Hampstead General and North-West London Hospital, £2000; Hospital for Consumption, (Brompton including Sanatorium at Frimley), £3000; Hospital for Epilepsy and Paralysis, £1200; Hospital for Sick Children (Great Ormond-street), £8000; Hospital for Women (Soho-square), £2000; King's College Hospital, £17,500; London Homœopathic Hospital, £3500; London Hospital, £35,000; London Lock Hospital, £1000; London Temperance Hospital, £3500; Metropolitan Hospital, £11,000; Middlesex Hospital, £10,000; Miller General Hospital for South-East London, £4000; National Hospital for the Paralysed and Epileptic, £8000; Passmore Edwards Hospital for Willesden, £1000; Prince of Wales's General Hospital, £7000; Queen Charlotte's Lying-in Hospital, £2000; Queen Mary's Hospital for the East End, incorporating West Ham and Eastern General Hospital, £6000; Queen's Hospital for Children, £6500; Royal Chest Hospital (City-road), £1000; Royal Free Hospital, £6000; Royal London Ophthalmic Hospital, £3000; Royal National Orthopædic Hospital, £2000; Royal Waterloo Hospital for Children and Women, £2000; St. George's Hospital, £8500; St. Mary's Hospital, £2000; St. Mary's Hospital for Women and Children, Plaistow, £1500; St. Thomas's Hospital, £12,000; Samaritan Free Hospital for Women, £1500; University College Hospital, £10,000; Victoria Hospital for Children, £1500; West London Hospital, £9500; Westminster Hospital, £9500; the remaining grants to 64 smaller hospitals totalling another £18,000.

In allotting the grant the Council of the Fund is asking each hospital to consider whether its income can, without detriment, be increased by taking some special steps—e.g., by the organisation of contributions from employers or from employed, or from patients who can afford to pay, or by other methods; and at the same time to take whatever steps may be necessary and practicable to keep the expenditure within the available or prospective income—e.g., by postponing bed extensions and by exercising more stringent control over cost of working.

PURPURA ANNULARIS TELANGIECTODES.

ACCORDING to Dr. Ludwig Weiss,¹ of New York, who records two examples with the biopsy findings in one case, this condition was first described by Majocchi in 1896. It is characterised by grouped or annular lesions, associated with pigmentation or discoloration and no thickening, but a tendency to atrophy. Three stages in the disease may be distinguished—a telangiectatic, a hæmorrhagic-pigmentary, and an atrophic. There are no inflammation, pain, fever, or other constitutional symptoms observable as in other purpuric conditions. As regards the ætiology of the affection, almost all diatheses have been suspected, only to be

¹ Medical Record, June 5th, 1920.

¹ The Archives of Dermatology and Syphilis, May, 1920.

excluded, such as tuberculosis, syphilis, rheumatism, gout, diabetes, heart disease, hæmophilia, and lead poisoning. Out of 38 cases collected by Mackee in 1915, 31 occurred in the male sex. Auto-intoxication is regarded by most authorities as the causative agent, but until this is definitely established the treatment can be only symptomatic. Rest and an elevated position of the limb, with the use of embrocations of Burow's solution, will prove useful. Calcium lactate may be given to increase the viscosity of the blood, and later strychnine and arsenic should be administered. The use of a porous bandage without rubber, to exert an even pressure, has also been recommended.

THE HOSPITAL SURVEY.

Sir Napier Burnett has now presented to the Red Cross Joint Council a survey of the financial position of the voluntary hospitals throughout Great Britain and Ireland for the five-year period 1914-19. His inquiry was directed to ascertaining the total amount of ordinary income and expenditure for each of these years, along with the total value of legacies not earmarked for specific purposes. The conclusions to which he comes, stated baldly, are that the voluntary hospitals in this country, taken as a whole, are solvent; that there is a deficit on the five years running of about a quarter of a million pounds for the provincial hospitals (and a similar sum in London); and that a further sum of three-quarters of a million is required to meet the accumulated cost of repairs and necessary alterations in both metropolitan and provincial hospitals. A covering letter from Sir Arthur Stanley states that if the voluntary system is to continue, five things are necessary:—

- (1) Payment of war debts, preferably by existing voluntary organisations, or, failing that, by a grant from the Exchequer.
- (2) The extension of the almoners' system, under which a contribution towards their maintenance is requested from those patients who can afford to make it.
- (3) The organisation of systematic collections from work-people and employers of labour.
- (4) The establishment of a competent authority to examine hospital accounts and consolidate appeals.
- (5) Closer co-operation with the Poor-law infirmaries in which there is a large number of vacant beds that might be utilised to relieve the pressure on existing voluntary hospitals.

We shall take an early opportunity of commenting on the figures from which these important conclusions are drawn.

IMMEDIATE SELF-DISINFECTION AND THE MINISTRY OF HEALTH.

AN influential deputation from the Society for the Prevention of Venereal Disease was received by Dr. Addison, Minister of Health, on July 2nd, when Lord Willoughby de Broke submitted the following resolution:—

That inasmuch as the Ministry of Health has failed, and public bodies, including the London County Council, have declined, to provide the means of delayed disinfection against venereal disease at ablation centres, this meeting calls upon the Ministry of Health and upon local authorities to instruct all qualified chemists to sell such means of immediate self-disinfection against venereal disease as may be approved from time to time by the Ministry of Health or by medical officers of health.

He added that while everybody was agreed that all the influence of research and administration ought to be applied to the prevention and cure of venereal disease, and that all means of moral prevention ought to be constantly employed, especially with regard to the youth of the nation, the society which he represented was addressing itself to the efficacy of immediate self-disinfection, and the policy it recommended was that the Ministry of Health should take such steps as would educate the public in the whole hygiene of this important subject. Captain W. E. Elliot, speaking as a medical Member of Parliament, said that the House of Commons was intensely interested in the prevention of venereal disease, and felt that unless stronger arguments could be brought against it than had hitherto been the case, it could not continue to accept the responsibility of prohibiting the sale of disinfectants which had the approval of the medical

profession. Dr. J. H. Sequeira stated that the number of new male patients, mostly ex-soldiers, suffering from syphilis, admitted for treatment at his clinic at the London Hospital in 1919 was 90 per cent. above the number attending in 1918, and that there was an increase of 15 per cent. in the total of female patients. The increase in cases of ophthalmia neonatorum and lip chancres proved that there was a definite increase in venereal disease, and that increased attendance at clinics was not merely the result of the spread of knowledge of these diseases amongst the people. Sir Archdall Reid stated that about 40,000 men passed through his hands during the war, and up to 1917 there was a vast amount of syphilis. In the beginning of January, 1917, a policy of immediate self-disinfection was advocated among the troops under his command, with the result that venereal disease practically disappeared. Mr. Wansey Bayly said that 14 borough councils, including West Ham and Holborn, in the metropolitan area, had adopted the policy of the society, and that the National Birth-rate Commission in its last report had expressed the opinion that the methods for the prevention of venereal infection by immediate self-disinfection should not be withheld from the public. Dr. A. Mearns Fraser reported his success in inducing the public at Portsmouth to accept the principle of immediate self-disinfection. Dr. C. W. Saleeby, Lady Askwith, Sir William Arbuthnot Lane, and Sir James Crichton-Browne also spoke.

Dr. Addison, in reply, said that they did not really know whether venereal disease was increasing or not, because they had no data supplied of a properly ascertained scientific kind. They knew that there was a great increase of people attending centres or clinics. The propaganda of the society represented by the deputation and the general public enlightenment were perhaps bringing people to realise that they must be properly treated. At all events, they had not got a basis of ascertained fact on which it was quite safe to dogmatise. It was suggested that the Ministry should issue certain instructions to local authorities and to the public, and he pointed out that it would be necessary to have an overwhelming case to justify such action and to avoid the conflict of opinion. They would have to contend with a great wave of public feeling which would suggest that the Government was really encouraging vice. It had been urged by the deputation that their suggested policy would be successful if scientifically and thoroughly done. That might be a true statement. They could not however, deal with a population of 40 millions on the same basis as Sir Archdall Reid, with iron discipline at his command, could deal with 2000 soldiers at one time. That was quite different from placing something at the disposal of any citizen with certain instructions as to use. They had to have a very strong case that would meet the intense and vehement opposition which such a proposal would arouse, and if they were not successful it would put the whole movement back a generation. There would be great objection raised, and he thought they must admit that a great deal of it would be well founded. To adopt such a proposal towards the population as a whole—boys and girls, men and women—would be held, and he thought with material ground, as doing something which would tend to encourage people to run risks. Last year he appointed a very strong body of men, who had reported to him that certain drugs, if properly applied, were efficacious, but if these drugs were not properly or scientifically applied their efficacy could not be relied upon. They also reported that the use of such drugs gave rise to a false sense of security and encouraged the taking of risks, and that, in spite of the most careful instructions, the issue of packets to soldiers resulted in men who used them for self-disinfection still having infection. Could they rely, he asked, on the general public properly and scientifically using those things? Two experimental centres had been established under the Manchester corporation, and so far the results were encouraging. Those experiments in Manchester were being watched with anxiety. He assured the deputation that the Ministry was anxious to take any practical measures they could thoroughly

recommend for the prevention and treatment of the disease, and they were quite prepared, if they were certain of good results, to face novel methods.

CHARLES MAYO AND THE AMERICAN HOSPITAL IN LONDON.

A DINNER was held at Claridge's Hotel, London, on Tuesday evening last, with the double object of paying a high compliment to Dr. Charles H. Mayo, the famous American surgeon, of Rochester, Minnesota, and of introducing to public notice the movement, rapidly advancing from theory to realisation, for founding an American Hospital in London. The hosts at the dinner were the President, Lord Reading, and Governors of the projected American Hospital, and the two toasts of the occasion were the health of Dr. Mayo, which was proposed by the Chairman, the Lord Chief Justice of England, and "Prosperity to the American Hospital in London," which was proposed by Mr. Balfour. Lord Reading disclaimed any ability to describe to an audience, comprising so many medical men, Dr. Mayo's professional position or the performances by which he had attained thereto, but dwelt on the fact that between the two great English-speaking peoples the inevitable links of race and language must be enormously strengthened by the interchange of scientific knowledge. Dr. Mayo gave a sympathetic sketch of what true intellectual union between England and America might achieve, and concluded a blood-curdling forecast of what war in the future would mean by stating that medical preparation to combat wholesale scientific destruction ought now to be made. Mr. Balfour, in wishing all good fortune to the American Hospital in London, concentrated upon the value of mutual understanding between America and this country on questions of medical science. He claimed, amid protests, to be the oldest man in the room, and having shown what enormous progress in medicine his span of years had witnessed, prophesied that this rate of progress would be accelerated in the future. He asked what could more surely assist to this desirable end than a practical exchange of their experiences between professors, teachers, practitioners, and even students of the two countries, such as could only be got by personal conference, and could never be supplied by any written medium. The toast was responded to by the American Ambassador and Sir Arbuthnot Lane. The American Ambassador rejoiced to know that London would soon possess an outward and visible sign of the graces of friendship and hospitality invariably extended by London to American visitors, and Sir Arbuthnot Lane then gave a rapid sketch of the activities which have culminated in the foundation of the American Hospital in London. The original idea of the institution he attributed to Mr. Philip Franklin, and he showed how on both sides of the Atlantic that idea had quickly taken root and had been developed by the energies of prominent citizens, medical and lay, until now a great institution was arriving, certain to achieve much in the future, alike in the promotion of a good understanding between the two English-speaking countries and in the facilities for research afforded. Sir Arbuthnot Lane, like all the preceding speakers, paid tribute to the great career, so sadly cut short, of Surgeon-General Gorgas, whose life-work formed a perfect example of what internationalism in medicine can achieve.

Sir Thomas Clifford Allbutt is to be sworn a Member of the Privy Council. The honour is the more signal when it is noted how few of the present Privy Councillors have become such on the ground of scientific attainment, while, as far as we know, no doctor has ever before attained to this distinction in recognition of pathological and professional work.

INDEX TO "THE LANCET," VOL. I., 1920.

THE Index and Title-page to Vol. I., 1920, which was completed with the issue of June 26th, are given in this number of THE LANCET, and will not be issued separately.

THE BRITISH MEDICAL ASSOCIATION. EIGHTY-EIGHTH ANNUAL MEETING AT CAMBRIDGE.

THE 88th Annual Meeting of the British Medical Association was concluded last week, and on all sides those who assisted in the session have had reason to be satisfied with the work achieved, as well as with the facilities provided so generously by the University and city of Cambridge. And Cambridge was arrayed by nature for the occasion, the noble colleges and ancient streets being radiantly beautiful in the perfect summer weather.

The final ceremonies included a dinner party in Gonville and Caius College given by the President of the Association, Sir Clifford Allbutt, who is a Fellow of the College; a reception at Emmanuel College by Dr. Peter Giles, the Master of the College and Vice-Chancellor of the University; a reception by the Mayor of Cambridge at Christ's College; a reception by the Master and Fellows of Trinity College; and the Annual Dinner of the Association, held by permission of the Master in the Hall of St. John's College.

The last item on the scientific programme was the Popular Lecture, and this was delivered by Dr. G. S. Graham-Smith, who took as his subject "Flies," and once again emphasised for public information the primary part played by flies in the dissemination of disease.

SECTION OF MEDICAL EDUCATION.

THURSDAY, JULY 1ST.

This section opened with five papers on

The Place of Preliminary Science in the Medical Curriculum.

The papers were an address on the subject generally by Sir GEORGE NEWMAN, President of the section; addresses with reference to particular sciences by Professor Arthur Smithells (Chemistry), Professor Sydney Hickson (Biology), Professor Arthur Keith (Anatomy), and Professor Sir Ernest Rutherford (Physics), and a paper by Professor Lorrain Smith on the connexion between the teaching of preliminary science and pathology. Professor Lorrain Smith's paper is published elsewhere. The discourses were taken as read, the authors merely outlining the essentials in brief speeches for the purposes of debate.

The PRESIDENT commenced by calling the attention of the section to the distinction of the men who were contributing to its work and hoping that something practical, perhaps in the way of resolutions, would emerge from the debate. Passing to the consideration of the subject of medical education in general, he said that the purpose of a medical education is the equipment of the practitioner in knowledge and skill. The curriculum must incorporate the principles of medicine as interpreted in current knowledge. It must also comprehend its practice in relation to the needs of the time and the art of the practitioner. Sir Clifford Allbutt had explained that the new birth of medicine "is nothing less than its enlargement from an art of observation and empiricism to an applied science founded upon research; from a craft of tradition and sagacity to an applied science of analysis and law; from a descriptive code of surface phenomena to the discovery of deeper affinities; from a set of rules and axioms of quality to measurements of quantity." Nor were the signs of expansion limited to practical medicine; there was the new work on the cell—in physics, in chemistry, and in biology. The cell theory—cell basis, cell division, the nucleus, the nucleolus—is yielding its secrets, and something of the hidden powers of the chromosome of the germ cell and the internal secretion of chemical substances, whether they be hormone, toxin, or antitoxin, is now revealed. It would seem impossible to exaggerate the effect on the science of medicine of the new knowledge of the chemical and electrical changes going on in the cells of

living tissue. Secondly, the character of the curriculum would also depend upon the medical needs of the time. To-day there were two special factors at work—(a) the new claims of the State upon the doctor, social, scientific, clinical, and (b) the further development of clinical teaching within the curriculum—making their insistent demand on the student.

The establishment of "clinical units" was but an expression of the growth of integration. His teaching work, instead of being casual, secondary, incidental or spasmodic, would now become the chief task of the clinical instructor. Moreover, the unit consisted of a staff of competent men working as a group or team who pooled their experience, and there was full integration of the science and art of medicine and surgery, the teaching of which might thus be raised to university standard. The association of research with intimate and intensive study, which should comprehend Sir James Mackenzie's subjective and associated phenomena, should investigate the mechanism of symptoms, and should follow end-results back to their origins, was the third advantage secured by the clinical unit system.

It was by the gradual evolution of this unit method over many years that the necessity of further development in the curriculum had become obvious. Not revolution but reform was needed, and even reformers must have regard to the facts (a) that the scope and character of secondary education was not yet settled, (b) that medicine itself was in a transitional state, and (c) that the policy of the nation in regard to the ultimate nature of the public medical services had not yet crystallised itself. However, it would appear that the four main reforms needed in the medical curriculum were: 1. A lightening of the curriculum at both ends; in other words, fuller preparation in science before entrance to the medical school, and a postponement of instruction in certain specialties and in general practice to the post-graduate period. This question of lightening without lengthening the curriculum was of cardinal importance, as in the present overloaded condition of the five years there was insufficient time allowed for true study, for digestion and assimilation. Several remedial steps might be suggested. Elementary physics and elementary inorganic chemistry might be taken at the secondary school, though preliminary science for medical students must be undertaken in the medical school; *materia medica* might be greatly reduced; the didactic lectures might be diminished in number; some overlapping might be eliminated; each term might be extended by a week and the medical course commenced in April; specialism might be unloaded from the final year or at least reduced in bulk; and above all the degree examinations might be shortened and modified by assessing the class examinations as an essential part of them. 2. A fuller study of the sciences preliminary to medicine and a nearer application of these subjects to clinical work. Above all, there was great need of biology (anatomy and physiology). Its principles were the answer to many questionings. It was the fundamental theme. 3. Development of clinical teaching of university standard. 4. There was need of further State aid, though with a minimum of State control. The education of the medical man was no longer a proprietary or merely professional interest. It was of national concern, for the health of the people was the principal asset of the State.

In the course of a few introductory observations on the place of preliminary science in the curriculum Sir George Newman said that in the first place it seemed evident that the development of clinical medicine and surgery in response to the demands of the age made a new and clear call for the improved teaching of the preliminary science subjects. Some advocated their removal from the medical curriculum, but he was convinced that they were more essential than ever. Physics, chemistry, and biology were key-subjects, absolutely fundamental, which formed the basis of a general education in science, and were the only basis of sound generalisation. The great medical subjects consisted of physics, chemistry, and biology applied to the life, form, and function of the human body in health and disease.

The patient was a case of anatomy, of physiology, of pathology to be interpreted and treated on grounds and by means which were essentially physical, chemical, and biological.

Sir George Newman gave examples of the application of the principles of mechanics, heat, light, sound, electricity in medical practice, and of the extent to which biochemistry and chemical physiology depended on organic and inorganic chemistry. He pointed out also the need of a closer association between physics and chemistry on the one hand and biology and medicine on the other. He recalled Huxley's warning that teaching in biology cannot be attempted with success until the student has attained a certain knowledge of physics and chemistry; for although the phenomena of life are dependent neither on physical nor chemical but on vital forces, yet they result in all sorts of physical and chemical changes, which can only be judged by their own laws. Happily, the relation between chemistry and medicine was being drawn closer. At Edinburgh there was to be a laboratory for clinical therapeutics in the hospital, the teacher of chemistry was to lay the foundations of physiological chemistry and clinical chemistry, there was an advanced course of medical chemistry for third and fourth year students, and after October, 1921, students beginning the study of medicine would have to pass an entrance examination in elementary chemistry before admission. As to biology its claim was supreme; it was the very essence of medicine, which, indeed, was but one of its forms and expressions. It was not an introduction to medicine, but its foundation. If the medical man were not a biologist he was nothing. But there was a still more important aspect of biology than that which was immediately utilitarian—namely, as the basis of comparative medicine. If there were one thing more than another which was lacking in English medicine it was its comparative study. Human anatomy, embryology, and physiology were parts of comparative anatomy; we built up our knowledge of man by study of the structure and function of animals. Likewise human pathology should be studied as part of a comparative pathology affecting both animal and vegetable worlds.

Sir George Newman indicated two ways in which progress can be made. First, biology itself can be brought into a larger place in the curriculum instead of being, as in some medical schools, relegated to a subordinate position or even neglected—unequipped laboratories, poor salaries, little opportunity, perhaps feeble apprehension. Biology must be taught in the right manner, and in due time the course might be transferred from the first to the third year. Due emphasis should be given to the comparative study of the development of the ectoderm and endoderm, the origins of the blood and nervous systems, the functioning of sense organs, the formation of the body cavity, mesenteries, primitive excretory organs, the alimentary canal, and the processes of digestion and absorption. The comparative study of protozoology, helminthology, and parasitology, and their relation to disease in man is the final issue of the course. Still another point to be borne in mind is the application of biology to society in the science of sociology, where Huxley and Herbert Spencer led the way. Sir George Newman considered the two chief needs of English medicine: (a) the fuller integration of its several branches and constituent parts, and (b) its new relationship to sociology.

He concluded: It is not only a device here or an adjustment there that is needed, it is the biological outlook and spirit that is required—the capacity "to see great truths than touch and handle little ones"—for biology, pure and applied, is the most educative, germinative, and dynamic subject of the whole curriculum. It opens the windows of the mind, it makes possible a conception of the unity of things, and it gives proportion and measurement through the entire range of medicine.

The Teaching of Chemistry.

Professor ARTHUR SMITHELLS spoke of the teaching of chemistry to medical students. He said that no one could fail to be struck by the greatly increased number and importance of the applications now being made of physics and chemistry to advance the art of healing.

Modern physiology alone had been brought to such a condition that for its full comprehension a really sound and substantial knowledge of chemistry of university standard was quite indispensable. It was universally agreed that some knowledge of the crudest facts of chemistry was quite indispensable for the medical man. Such knowledge could be picked up very quickly by anyone of moderate intelligence; it was not of necessity a serious mental exercise or intellectual outfit, and it would seem to be a matter of little importance when or where it was acquired. The teaching of chemistry conceived in this spirit was not, however, very exhilarating either to teachers or students. The dissatisfaction at present bound up with the teaching of chemistry to medical students was due mainly to the feeling among students and even among doctors that the study of preliminary science was a penalty rather than a privilege, an obstacle to be passed before one could enter upon the highway of true professional study, not a foundation to be built upon, not something to be assimilated and incorporated with succeeding knowledge.

The mere phrase-book knowledge of chemistry was certainly far from satisfying the declared aspirations of those who ultimately control the whole of medical education, and lay stress upon a proper grasp of scientific method and a scientific attitude of mind which will permeate all subsequent studies. Professor Smithells proceeded: "I think it must be admitted that we who have been teaching science in universities have failed very decidedly to achieve this end, and that somehow or another we have gone wrong. The little regard that our work has earned is shown by the deliberate act of the profession in affirming that all that we have done can now be perfectly well done at school. This means, of course, that we have neither specialised our teaching effectively towards medicine nor given it any intellectual weight which makes it the sort of thing that can only be reasonably expected from a university."

When considering schemes for arousing greater interest in chemistry in the medical student Professor Smithells suggested that professional teachers were very apt to go wrong by attributing to the average student the same sort of capacity for interest in abstract studies as they themselves, by their very nature, possessed. Some years ago Professor Smithells had decided to separate the medical students from others taking the elementary course of chemistry with the object of altering the substance and form of the teaching as far as seemed legitimate towards bringing it into closer relation with matters of special concern to the student of medicine. It seemed to him remarkable that in those universities where the teachers were their own masters so far as examining was concerned, and where they were practically free to go their own way, so little had been done to introduce a directional element into the preliminary scientific studies of medical students. Happily, there was now evidence of a considerable change. Without interesting the students it was not easy to teach them, but it was both possible and legitimate to invest even elementary teaching with a topical character. It was noteworthy that the University of Edinburgh had lately established a chair of chemistry in the interest of students of medicine, occupied by Professor G. Barger, who had explained the general lines on which he was proceeding in a letter which Professor Smithells read to the meeting. The letter began as follows:—

"It is proposed that I should ultimately have under my control (directly or indirectly) the whole of the chemical teaching of medical students, including physiological and clinical chemistry, but for the present I am teaching only inorganic and organic chemistry to first-year students and giving occasional more advanced lectures on special subjects. No previous knowledge of the subject is at present required from students entering my class, but in October, 1921, a new regulation comes into force which will demand from students coming to me an elementary knowledge of inorganic chemistry, at least up to the standard of the London Matriculation." Professor Barger then proceeded to give details of the syllabus and time allotted to various branches of the subject, and explained the principles which guided his method. He had convinced himself that before taking his degree the average medical student forgets most of the chemistry he learns in his first year. Hence he laid great stress on general principles, but mentioned little detail. Since he lectured to medical students *only*, he could afford to omit such

things as the metallurgy of copper, and could illustrate general principles by examples of medical importance. His main concern was to make a basis for physiology, and hence dealt with the fats, carbohydrates, and something of the proteins pretty thoroughly, but said little about benzene compounds. According to Professor Barger, "the interest of the students is at once aroused when they grasp that they are being taught with a view to their later professional studies, and they always respond to efforts to help them in this direction."

Professor Smithells considered it desirable that medical students should be taught some chemistry at school. It was extremely difficult to do anything effective in a single year with students brought to the university at the age of 17 or 18 with not even a rudimentary knowledge of scientific facts and with their scientific faculty almost atrophied. Many medical students now had been taught chemistry at school, and in recent times the science teaching in schools had improved remarkably; but he looked upon the intensive study of science in school years with great distrust, based upon the painful experience of having had to deal much with students who arrive at the university in that worst possible plight of having a large mass of undigested knowledge and a feeling (which so far as facts are concerned might be largely warranted) that they had heard before all that would be told them. Moreover, a year in a university atmosphere ought to do something towards producing a maturity of thought, a breadth of scientific outlook, and a general intellectual stimulus that could not easily be impressed on school boys in the environment of school. But considerable reform in university teaching of chemistry must be made if the claim for university as opposed to school teaching was to be substantiated. Whatever was done in relation to the quantity of chemical teaching of medical students Professor Smithells was convinced that its quality might be greatly improved. Medical men were not often in possession of a live and available knowledge of even the fundamental principles of chemical science, and many of them regretted their inability to keep in satisfactory touch with the abundant and profoundly important discoveries now being made on the borderland of medicine and the exact sciences.

In conclusion, Professor Smithells said: "I feel that it is incumbent on us who are charged with the teaching to make a drastic reform, and I am confident that this can be done in such a way as to justify fully the retention of chemistry as an integral part of the university medical curriculum."

Physics in Medical Education.

Professor Sir E. RUTHERFORD, in discussing the place of physics in medical education, said that in several of the universities, and notably in Oxford and Cambridge, the able students were advised to take a degree in pure science before or during their professional studies, and there could be no doubt of the great advantage to the profession of having a regular supply of able men whose training in science had been sufficiently broad and deep to take full advantage of the subsequent teaching. It was not, however, feasible for various reasons to expect the great majority of medical students to follow such a course. In his remarks he proposed to deal mainly with the pressing question of the scientific education of the *average* medical student leading up to the first M.B. The general opinion among those who had to do with the teaching of medical students in our universities for the first M.B. was that the existing state of affairs was highly unsatisfactory and called for drastic changes. He continued: "The best method of dealing with the present unsatisfactory situation seems to me to require a preliminary knowledge of science, and particularly of physics and chemistry, before admission as a medical student. This preliminary training can best be given in our schools, where, instead of being concentrated in a brief course, two years or so may be devoted to gaining a sound knowledge of some branches of physics and chemistry. The element of time is, to my mind, of great importance in gaining a grasp of scientific principles, and for this the present university training is much too concentrated." On admission of the student to the university he would have had a sufficient preliminary training to gain full advantage of the university instruction. This teaching

should preferably be given by a man of high scientific standing with some knowledge of, and interest in, the application of physics to medicine. The course should not be a repetition of the subjects taught at school but devoted mainly to a consideration of the properties of matter (electricity and magnetism), and possibly a consideration of the theory and use of optical instruments employed in the medical profession. Under properties of matter special attention would be directed to subjects like surface tension, diffusion, osmosis, &c., which were of special importance in physiological processes. A sound knowledge of the elements of electricity seemed to him essential, for not only was it of direct practical importance in several branches of the profession, but electrical ideas tended to become of increasing importance in the explanation of underlying phenomena. The aims of this course would be not to require a knowledge of a multitude of facts, but to give the student a clear understanding of the fundamental ideas of the subject and of their application in medicine.

Professor Rutherford said that his remarks applied particularly to physics and chemistry. Biology presupposed a reasonable knowledge of physics and chemistry, and since it was not likely that our schools would be capable for some time to come of providing good instruction in all these subjects, it might be desirable that biology should be taught by the universities as at present. It might ultimately prove desirable to give in addition a short course of medical physics at a later period of the medical curriculum. The third-year student was in a better position to realise the importance of physics in his more professional studies. Such a course would be analogous in some respects to the course of biochemistry which is given to medical students in Cambridge in their third year.

Courses of Study in Science for Medical Students, with Particular Reference to Biology.

Professor SYDNEY J. HICKSON opened the discussion on this subject. He said that the general result of changes in the last 40 years had been to bring the standard of medical education required both for those students who are contented with the ordinary qualification of the Royal Colleges and for the university degree students to a more uniform level. In attempting to map out the courses of study in science that should be given to medical students as a whole it was necessary to assume that potentially any one of them is capable of taking a position in the highest ranks of the profession. Any one of them might become a consulting physician or surgeon, a distinguished investigator of medical science, or a writer of standard works of reference. A course of study wide enough for a man who is to play a leading part in the profession could not be framed without including some subjects which might not be of much direct practical value to the man in a humble country practice unless the General Medical Council directed the provision of two distinct avenues, a higher and a lower, to a medical qualification, the same opportunities to acquire distinction must be offered to all students.

The question of the most suitable science courses for the first-year medical student was so closely connected with the question of his school education that it was necessary to consider what standard of education is, or should be, required before registration. At the present time a very large proportion of the students who enter the medical schools have no knowledge of any of the sciences. Those in charge of the first year science courses, therefore, had to begin with the most elementary general principles. On the other hand, the smaller number of students who have had some instruction at school in chemistry, physics, and perhaps botany, might regard their first three months at the medical school as a waste of time. It was not desirable or practicable to grade first-year medical students, and the difficulty would have to be met in another way. The real difficulty with all science classes in the first year of medical study is caused by a minority—but often a substantial minority—of students with a low standard of school education. These students act undoubtedly as a certain drag upon the machine. The time had come to demand a higher standard of

general education before a student is registered. The first step would be to insist that the lowest standard accepted for registration should be that of the matriculation examination of our universities.

It had been suggested that, in order to provide more time for clinical work in the later years, the preliminary science studies should be transferred to the school period of the student's education. It would undoubtedly be an advantage if every student before entering a medical school could present a certificate of attendance on science classes in school or at a college, but Professor Hickson believed it would not be in the interests of the students, nor of the medical profession as a whole, if the standard required were in any degree lowered. There were not many secondary schools in which the standard of the First M.B. Examination in Physics and Chemistry could be reached, and very few in which any provision was made for the teaching of biology, and in consequence such a transference of science subjects to the schools at the present time would inevitably lead to a lowering of the standard. But whether there was to be a preliminary training in science in the schools or not, the first six months at least of a medical student's career in a university should be spent in the science departments.

In dealing with the subjects taken in the first year of study Professor Hickson thought it might be assumed that chemistry and physics were essential. It would be a hopeless task for any teachers to attempt to carry students into any branch of medicine unless they could assume some knowledge of the elementary principles of these sciences. Perhaps in the near future when the science courses in schools were longer and better, the teaching given to registered medical students in physics and chemistry might have a more direct and practical bearing upon medical science.

Professor Hickson then proceeded to discuss in more detail the courses in biology which he had taught to medical students for nearly 40 years. He believed that by the medium of biology even better than by other sciences, the teacher could instigate and stimulate the power of cautious thinking so necessary to the medical student. This might be the most important object of the course in biology, but it was not the only one. Before passing on to courses of study in human anatomy and physiology, some introductory course of training in biological nomenclature and methods appeared absolutely necessary. The student in the biological department learnt for the first time to verify the facts of anatomy by dissection, to use the scalpel, forceps, and scissors, to manipulate the microscope, and became familiar with the meaning of many words and expressions used in the subsequent medical courses.

There was another direction in which the course in biology might be made of great value to the future medical man. It might be urged, and perhaps with some justice, that the kind of training of hand and mind that I have already mentioned could be acquired by the courses in anatomy and physiology. It could, but with much greater difficulty both for the student and the teacher. Moreover, if this training was left to anatomists and physiologists, the courses in these subjects must be either lengthened or greatly simplified. Further, there were some things that might be of immense value for the medical man which could, and should, be taught in the biological course and could not, under ordinary circumstances, be dealt with at any later stage in the medical curriculum. In his address to the International Medical Congress in 1881, the late Professor Huxley said: "Historically the connexion of medical science with the biological sciences and the full extent and intimacy of that connexion are only now beginning to be apparent." Again: "It is a peculiarity of the physical sciences that they are independent in proportion as they are imperfect, and it is only as they advance that the bonds which really unite them all become apparent." Again, Huxley himself would hardly have ventured to predict how rapidly the advance of knowledge would reveal the bonds that unite biology to the medical sciences. Medical protozoology, entomology, parasitology, and the advancing knowledge of

the laws of heredity derived from biological research, all formed a series of most important links with medical science. Professor Hickson declared that there was only one time in the career of the medical student when the nature of these links between medicine and biology could be indicated, and that was in the course of his biological studies during the first year. In order to allow more time for the realisation of these ideals, the first step in reform must be a reduction in the number of "types" of which a detailed knowledge of structure is required. The type system, however, could not be entirely abolished, and a general knowledge of the anatomy of such forms as the frog, the earthworm, and hydra should be given as an introduction to the study of animal structure, as a training in anatomical method, and as a means of cultivating objective study.

For another purpose there should be given some lectures and laboratory work on an Elasmobranch fish and on a Mammal, but detailed knowledge of the whole anatomy of these vertebrates should not be required. Presumably the dogfish was first introduced into the first M.B. biology schedule for the purpose of assisting the student to understand the complex anatomy of the human head and neck, and Professor Hickson believed that it had admirably served this purpose. But while careful instruction should be given on the heart and arterial system, on the brain and cranial nerves, on the visceral arches and their relations, and also on the kidneys, there were many details of the structure of the dogfish which might well be omitted, and the same remarks would apply to the mammal.

In dealing with the three vertebrate animals referred to, some lectures must be devoted to the question of the fertilisation of the ovum and its segmentation, to the formation of the germ-layers, and to some of the elementary facts about the development of the organs. Facilities for adequate laboratory work might vary in different schools, but at least the early stages of the development of the frog and the first three days of the development of the chick from the beginning of incubation could be demonstrated. The study of some selected examples of the protozoa brought the student into contact with the fundamental phenomena of things that are alive, with protoplasm, which Huxley so aptly called "the physical basis of life"; with the essential features of nucleus and cytoplasm; with the function of sex; and with the problem of death.

Professor Hickson declared his strong conviction that some acquaintance with these fundamental problems should be a part of the equipment of every medical man, and he also considered as an essential part of the course some instruction in those lines of advance which bind more closely biological and medical science. He then gave a few examples to illustrate his meaning. In the biology course at Manchester he had for some years past given a short account of the structure and life-history of the house-fly (*Musca domestica*), demonstrating the difference between the house-fly and the stable-fly (*Stomoxys calcitrans*). A few words of explanation of the different ways in which these two insects might carry infection were quite sufficient to convince the medical student that he was learning something with a direct bearing on his professional work. In dealing with the protozoa some reference should be made to the systematic position and life-history of the malaria organism, of the trypanosomata, and of the entamoebæ of the human intestine. A full account of these organisms should be left to the later studies in the departments of pathology or public health, but some reference to them in the first year should be made in order to clear the mind as to the relation between the two sciences. There were many other subjects of the same kind, such as the story of ankylostoma, bilharzia, and of the human cestodes, an outline of modern researches on heredity, and the zoological position and special characters of man. These subjects need not be included in a rigid schedule, on the principle of "no more and no less," but teachers should be encouraged to indicate to the students more definitely than they had done in the past the bonds that bind together the sciences of the first year with those of the later years of their medical career.

The course should be widened in its basis to make it less an effort of memory of details and more an introduction to a wide field of scientific thought. The facts in themselves did not matter much; they were the scaffolding which enabled the structure of a medical education to be built up; and if they had performed their function of giving strength and purpose to the design as a whole they could be discarded.

Speaking of botany in medical education, Professor Hickson said that many of the remarks he had made about the zoological part of biology applied with equal force to the botanical part. He considered that "the study of the organisms that lie on the vegetable side of the imaginary line that divides the animal from the vegetable kingdom, the yeasts, the bacteria, the fungi, and the lower algæ, is so intimately connected with the more advanced studies in cellular and chemical pathology that it forms an almost essential part of the medical curriculum." As an introduction to the experimental methods of physiology botany provided perhaps the most useful assistance to medical education.

The Teaching of Anatomy.

Professor ARTHUR KEITH in opening the discussion on Anatomy said that the problem to be faced was not how to improve the education of the medical student, but how to educate and reform his teachers. The suggestion to get rid of specialisation and to pick professors from the best equipped general practitioners could not be followed without arresting the progress of medicine. Without specialisation there could be no progress. "No man is fit to profess or teach any branch of knowledge unless he has a first-hand experience of his special branch, and is not only capable of adding to its stock of knowledge, but of showing his pupils how improvements can be wrought." The real problem was how a staff of specialist teachers was to produce an army of effective medical practitioners. Was it too much to expect every medical teacher to keep his professional knowledge in such a state that, if called upon, he could resume or assume the rôle of general practitioner? Professor Keith did not think so. With a reformation in the medical teacher of this kind the distinguished specialist whose vision is limited to his own specialty—be it physiology or surgery—would become more rare. Another narrow, and he thought mistaken, outlook on the part of many distinguished teachers led to the attempt to raise a school of research students. If the teacher applied himself to meet the needs of the ninety-nine who are to practise medicine generally or some special department, he would not fail to waken the latent qualities of the one promising research student who might be found in the average class of 100. For the qualities which make a student an instrument of research could not be bred in him if they had not been born in him. Here again the need of reform lay with the teacher.

One other matter needing reform was the scope of our text-books. There was a time when a student's text-book could be a complete repository of all the known facts relating to any particular subject. It was an encyclopædia to which teachers and taught referred if they desired to ascertain the extent of knowledge on any particular subject. "Our standard text-books still strive to serve as works of reference for the research as well as for the pass student. The time has come when a clear distinction must be drawn between the student's text-book and the work of reference. As time goes on the difference between them must become greater and greater. The greatest sinners in this respect are the anatomists and physiologists; their text-books could be reduced by half, with an improvement in the education of the man who is to practise general medicine." Though the general practitioner probably put into practice not a single idea or fact gained in his preliminary studies, these subjects could by no means be excluded as unfit and improper for medical students. "For the man who is to become a master workman in medicine or for one who is to advance medicine in any way they are all of them necessary and invaluable, but they are not essential for the training of a highly qualified medical practitioner. They are for him matters of general education. The proper place of

all these subjects is in the science, not in the medical faculty of a university." Speaking specially of anatomy, Professor Keith commented on its application in general practice and spoke of the desirability of reform in textbooks and teaching. He concluded: "Anatomy could be made a living practical part of medicine if only the teacher would ask himself: Could this fact help me in diagnosis and treatment? If not, let that fact repose in the comfortable storage of his works of reference until it has proved its right to enter the currency of applied or applicable knowledge."

Professor J. LORRAIN SMITH then gave the address on the Relation of the Preliminary Science Teaching to Pathology in the Medical Curriculum, which appears in full at the front of this issue of THE LANCET.

The Discussion.

Dr. SIMON FLEXNER, director of the laboratories in the Rockefeller Institute, said that he did not intend to discuss the English medical curriculum, and humorously alluded to the constant confusion of his own personality with that of his brother, Dr. Abraham Flexner, who had studied European medical education. He said that it was axiomatic that education, and education alone, could put a fine edge upon generally infused talent; without appropriate educational methods the information imparted did not fructify, whereas a good system not only brought all the average to a higher level, but afforded opportunity for the best men to do the best work. This, he pointed out, was another way of saying that organisation in education is of the highest importance for all research work.

Professor PIERO GIACOSA, professor of pharmacology in Turin University, and recently engaged in the reorganisation of the Italian medical curriculum, in an address wherein the imperfect knowledge of English, for which he apologised, rendered his remarks the more forcible, inveighed against imitation specialism, and insisted that before a man made any attempt to specialise in a subject he should have a solid base of general knowledge from which to work, and then an organised period of intensive training. "Let the Germans," he said, "investigate Homer in the light of grammar, what modern research meant was an all-round understanding of the great central themes and the interacting problems involved." Professor Giacosa made an urgent plea to the section that they should work for the establishment of an International Committee which would facilitate a proper interchange of educational facilities between the nations.

Dr. J. C. MCWALTER having expressed his deep dissatisfaction with the existing methods of medical education and having illustrated it by a curious reading of vital statistics, Dr. R. C. BUIST corrected that reading and insisted on the necessity of an accurate preliminary scientific training for the medical student, saying that over and over again he had found it necessary to revitalise the scientific training of his students. Professor RAPER, Professor of Physiology and Biochemistry in the University of Leeds, with special reference to chemistry said that he himself happened to have done a considerable amount of that subject before entering the medical profession, but that he had found the repetition of that work during his student career most useful. His chemistry, when brought into association with clinical work, became a totally different thing from his earlier knowledge. He was able to replace cram by a more philosophical attitude.

Professor JAMES RITCHIE, Superintendent of the Conjoint Laboratory at Edinburgh, asked that the psychological aspect of training should receive attention in medical education, which should mould the student's character and mind, as well as his mental capacity. This would tell greatly in the transition from school to university training. Of the preliminary subjects, he considered physics to be the most important, and he repeated a point, previously made by Dr. Buist, that the great advance occurred when the student was able to consider quantity more than quality, and to perceive the value of accurate measurement. He urged also that the various scientific and professional subjects should not be taught in watertight compartments, but that there should be correlated

teaching, and that the interplay of the sciences, particularly in their medical connexion, should be made clear.

Dr. H. G. TANSLEY, in urging that the teachers of scientific subjects should concentrate in the essentials, found that instruction in biology was not treated sufficiently in this way.

Dr. F. O. BOWER, Professor of Botany in the University of Glasgow, pointed out that botany, properly taught, made an admirable introduction to medical studies, familiarising students with the common processes of life; he defended the system of set lectures by saying that the value of the work in all these discourses depended entirely on whether the lecturer was competent to deliver them. He saw no reason why training during general school life in physics and chemistry should not be quite good, but thought that the general schools of the country were not ready to instruct students in biology.

Dr. BRACKENBURY asked the meeting, when they were talking of the standards to be reached by students or to be displayed by professors, to remember that it was necessary for the practice of medicine that the general practitioner should also reach a high standard; he thought that this was just as necessary in his case as in the case of any specialist. He alluded to the unpractical nature of many examinations and many educational courses, and considered that the great need of medical students, in a revision of the curriculum, was a sound general education with which to approach physics and chemistry and biology up to a certain standard.

Dr. J. A. LINDSAY, Professor of Medicine in the University of Belfast, after endorsing Professor Ritchie's remarks on the mischief of teaching the preliminary sciences in watertight compartments, deplored the existing low standard of general education among medical students.

Dr. WARDROP GRIFFITH, Professor of Medicine in the University of Leeds, spoke on the necessity of a continuity in scientific studies. The medical curriculum must be lightened for the student, but, he pointed out, the education in preliminary scientific subjects ought to be kept alive and relied upon throughout the medical curriculum, so that if the student in the course of his clinical work came across "a bit of chemistry" he would understand it and apply the teaching properly.

Dr. CAREY COOMBS agreed with Professor Ritchie on the importance of some psychological training for the medical student.

Sir GEORGE NEWMAN read out to the meeting the following three resolutions which had been handed in:—

1. That the lowest age of registration for the medical student should be 17 years.
2. That in the forthcoming revision of curriculum promised by the General Medical Council the lightening of professional studies would be facilitated if chemistry and physics were made school subjects, biology remaining a professional subject.
3. That with a view to securing adequate training in physics, chemistry, and biology as applied to medicine by courses of these subjects within the professional curriculum, it is desirable to exact a knowledge of physics and chemistry of matriculation standard of all medical students before they are registered.

Professor A. E. BOYCOTT objected to the view implied in the second resolution, as he understood it, that the student's education in chemistry and physics should cease with his school career.

Sir GEORGE NEWMAN said that as the time allotted to the Section was now more than exhausted he would, with the approval of the meeting, submit the discussion and resolutions to the University Grants Committee, and to the Education Committee of the General Medical Council, where they would receive valuable attention.

NAVAL AND MILITARY SECTION.

WEDNESDAY, JUNE 30th.

This Section's proceedings began by an address from Colonel JOSEPH GRIFFITHS, C.M.G., F.R.C.S., the President, introducing a discussion upon

The Army Medical Service in Relation to the Education and Training of Newly-Qualified Men.

Colonel Griffiths, in a carefully reasoned paper, set out the arguments for the employment of officers of the

A.M.S., with whom he suggested those of the I.M.S. might coöperate in training the best newly-qualified doctors of the country for professional as well as administrative duties. Of the men undergoing such training, he said, those required by the Service, especially as administrators, could be kept, while arrangements could be made for placing the others in spheres of usefulness. He pointed to the double advantage of such a scheme, inasmuch as it would assist the young doctor exactly when supervision and guidance are removed, and would form an outlet for the accumulated experience of the army doctor, whose life fits him for a great variety of offices. The pensioned officer, he pointed out, did not cease to work because he was incapable, but is cast adrift by the system. Administrative or scientific posts ought to be available for such officers, while their experience would fit them admirably for training others.

Lieutenant-Colonel R. H. ELLIOT, I.M.S., said that he would not like to see State posts reserved in any way for retired officers. The positions of officers were now greatly improved, and such posts should go to the best men. He expressed the greatest sympathy for the way in which general practitioners did their work, and would like to see more of the administrative posts come their way. The good doctor is, he said, usually a good administrator.

Dr. C. A. BUTTAR, speaking after long and intimate experience of the work done at the Central Medical War Committee, urged that a liaison was necessary between the Services and the civilian practitioners, but, while so far agreeing with Colonel Griffiths, he desired to see the liaison take place not between departments or by any interchange of State posts. Colonel Griffiths would find that the best way of utilising the services of retired officers would be by approaching their civilian brethren, when he had no doubt some system of mutual coöperation could be evolved.

Colonel McMUNN pointed out that retired officers did not cease to function; the army still had a call upon them, and the needs of the army must come first.

Lieutenant-Colonel HARVEY called attention to the Directorates now in existence in the Army Medical Service whereby Directors of Hygiene and Pathology are appointed by the War Office of high rank, and men of special interests receive special training. In this way by his seventh year of service a man might be marked out for a particular line of work and could continue in that line while attaining to the position of colonel and even general. It was no longer necessary for a man to pass into pure administration to obtain high rank.

Gas Poisoning.

An extremely interesting paper was then read upon the German gas attacks by Colonel P. S. LELEAN, who humorously admitted that he had lectured on the subject before, and had found the occasion announced as "Poisonous Gas by Major Lelean." He described in vivid language the effects of the first treacherous attack with chlorine and the vigorous methods immediately devised by the R.A.M.C. at the Royal Military College, under Sir William Horrocks, to counteract the onslaughts. There was, he said, terrible slaughter of our front line during the first attack, especially in the centre, while the situation was partly saved by the action of a young officer on the left, who, with some idea of dissipating the fumes, ordered all his men to shoot, when the din of the ensuing firing persuaded the Germans that their foul device had failed, so that they did not advance to profit by what they had done. By the time the second attacks arrived masks had been made at headlong speed by an admirable combination of science, manual labour, and commercial efficiency. Of these 5000 arrived in 60 hours, 300,000 in a week, and 2,000,000 in a month. *The second attack led to 265 hospital admissions and 13 deaths.* Almost immediately after the treacherous surprise the defence got ahead of the attack. The Germans then started the employment of lethal gasses, and so numerous were the terrible poisons which, on high authority, it was said were going to be employed, that defensive preparations had to be prepared for no less than 43 of these gasses. More, the gasses themselves had to be made as the result of intensive research before methods of protection could

be devised. Colonel Lelean described the devoted work of the officers engaged in this work, who themselves submitted to terrible and prolonged tests in the lethal chamber to ascertain if the protective measures were efficacious, and efficacious over a sufficient period.

The last stage in gas warfare was the use of lachrymatories, and the reply to these was explained by Colonel Lelean, who also demonstrated the box respirators.

The paper was warmly applauded.

VENEREAL DISEASES.

THURSDAY, JULY 1ST.

This section was under the chairmanship of Mr. E. B. TURNER. Although the section is a new one it was very well attended. The largeness of the audience and the interest shown in the discussion so fully justified the formation of this new section that the chairman at the close of the meeting declared his intention of urging that on future occasions two days should be devoted to the discussion of venereal problems. Opening papers were read by Dr. MORNA RAWLINS and Dr. LEONARD FINDLAY.

Dr. MORNA RAWLINS dealt with the subject of venereal disease in women. After calling attention to the importance of the venereal problem, Dr. Rawlins discussed the question of treatment in syphilis. Three points of especial interest were brought forward: (1) the treatment of cases intolerant of arsenic and mercury; (2) the treatment of ante-natal syphilis; (3) the need of collaboration between the syphilologist and the medical officers of the special departments of hospitals. "Few medical officers working in venereal clinics can find the necessary time, even if they have the necessary skill, for careful examination of the special systems." For this reason such a medical officer should be able in case of doubt to utilise the special knowledge of his colleagues to prevent wrong diagnosis and to serve the best interest of the patient. For the treatment of those rare cases that showed a marked intolerance to arsenic or mercury Dr. Rawlins relied mainly on sulphur. This could be administered as collosol sulphur, sublimed sulphur, or intramine. The action of the last-named was particularly satisfactory and rapid, and could be taken advantage of in the treatment of mercurialism. In introducing the subject of ante-natal syphilis, Dr. Rawlins urged that more stress should be laid on clinical signs and history, and less on the Wassermann reaction. Treatment could be continued with safety right up to end of pregnancy. Even when begun as late as the seventh month the results of treatment had been very satisfactory. The treatment of gonorrhoea in women was, in the opinion of the reader of the paper, still in the experimental stage. Various preparations could be used in the treatment of the ordinary subacute case of gonorrhoea, the most useful being protargol (10 per cent.), eucalyptus oil in olive oil (40 per cent.), picric acid in glycerine (50 per cent.). Douches were of little use, but pessaries (protargol 10 per cent. or sauerin) were often beneficial. Before starting vaccine therapy a careful examination must be made for pelvic complications. If infection of the tubes and ovaries had taken place a much smaller initial dose of vaccine was advisable. Finally, before discharging a patient a very high standard of cure should have been attained. The more conscientiously this standard of cure was insisted on the less became the risk of relapse and of spreading the disease. Dr. Rawlins's paper was then discussed.

Sir JAMES GALLOWAY uttered a warning against the abuse of antisyphilitic remedies. He quoted cases that had been subjected to a severe course of treatment in the absence of any clear diagnosis of syphilis.

Dr. AMAND ROUTH advocated very energetic measures in the treatment of gonorrhoea in the female. In discussing the question of ante-natal syphilis he stated that he had come across several cases in which a positive Wassermann had become negative as a result merely of pregnancy. He believed that the placental ferments afforded some degree of immunity.

Dr. F. MACKENZIE urged that syphilitic women should be instructed how to avoid pregnancy in order that the

appalling harvest of defective and syphilitic children might be curtailed.

Mr. KENNETH WALKER claimed that the urgent necessity lay in providing these women with adequate treatment during pregnancy rather than in the prevention of pregnancy. The ante-natal treatment of syphilis was attended with astonishingly good results. A subject that demanded far more careful consideration, on account of the difficulty of treating it, was the subject of gonorrhoea in the female. Amongst other measures possible was the application of diathermy to the cervix. Although he had seen some very bad results from the use of electrical methods in the male, diathermy and electrolysis had given some satisfactory results in the female.

Colonel C. E. HARRISON agreed that the treatment of gonorrhoea in the female was still very unsatisfactory. The problem was one of drainage, and he was in favour of the use of glycerine-containing preparations rather than of strong caustics. Dr. Ainley Walker's work had suggested that the antigenic power of the blood might possibly be increased in the case of gonorrhoea by the use of such drugs as salvarsan in combination with vaccines.

The Treatment of Syphilis in Infancy and Childhood.

Dr. LEONARD FINDLAY, in introducing his paper on this subject, dwelt on the enormous loss of child-life that was directly attributable to this one disease. As an example of this could be quoted the striking figures obtained by Dr. Kerr Love, who collected the complete records of 21 families. Of the 172 pregnancies occurring in these families 75 ended in stillbirth, and of the 97 children born alive 31 were deaf or blind. Although the introduction of dioxidiarnarsenobenzol had enormously improved the results of treatment, syphilis in childhood still remained a very serious problem. When treated with mercury alone a mortality of 71 per cent. had occurred in a series of cases under 3 months of age. With combined treatment by means of mercury and arsenic this mortality had been lowered to 20 per cent. In administering mercury amongst infants the reader of the paper relied on instructions. Of the two methods of injecting salvarsan, intramuscular and intravenous, he preferred the latter. Intramuscular injections were practically always associated with pain and discomfort. For intravenous injections the veins of the scalp were employed. With the technique he employed the injection became a comparatively simple affair. In children over 2 years of age the veins of the scalp were, as a rule, not visible, and either the external jugular or the veins of the elbow flexure must be employed. An anæsthetic was often necessary in such cases. The initial dose for infants was 0.05 of neo-kharsivan, increasing to 0.15 or 0.20. In obtaining a negative Wassermann observations seemed to indicate that the duration of treatment rather than the total quantity of drug given was the deciding factor. The percentage of cases in which a negative Wassermann was obtained rose steadily with the number of injections given. Amongst older children this negative Wassermann was obtained with greater difficulty. In several children of 8 and 9 years of age as many as 20 injections had failed to convert a positive into a negative Wassermann. Once a negative reaction had been obtained it very seldom became positive again. Prophylactic treatment was the only rational method of treating congenital syphilis. When this had been carried out by means of mercury and potassium iodide alone relapses had been frequent, but the use of salvarsan generally resulted in permanent benefit. All the children born subsequent to treatment were free from disease. In discussing the question from the point of view of national health, the reader of the paper urged that all miscarriages and stillbirths should be notified. If subsequent investigation and blood reaction indicated that syphilis was the cause of the miscarriage prompt treatment should be undertaken. No antivenereal campaign could afford to neglect notification. Ophthalmia neonatorum was already notifiable, yet this disease was responsible for only 20 per cent. of the blindness of childhood, as compared with 30 per cent. due to syphilis. Serious

objections had been raised to notification in the case of tuberculosis, and yet these objections had been overcome. The ideal treatment of congenital syphilis meant treatment of the syphilitic mother, and in order that this should be effectually carried out compulsory notification was a *sine qua non*.

Dr. DOROTHY BUTCHER confessed to harbouring conservative views with regard to the treatment of syphilis. She placed great reliance on hyd. cum creta, but insisted that the preparation must be fresh and free from signs of oxidation.

Dr. AGNES DUNNETT asked whether in cases of repeated stillbirth with a consistently negative Wassermann it was advisable to insist on treatment.

Professor PECHÈRE (Brussels) complimented Dr. Rawlins and Dr. Findlay on the excellence of their papers. He was an enthusiast in the use of arsenical preparations for congenital syphilis. He agreed with Dr. Rawlins on the benefit to be obtained from sulphur, and had obtained very satisfactory results from the use of a new preparation, sulpho-arseno-benzol. Personally he had employed the intramuscular route, but after having listened to Dr. Findlay he would test the intravenous method. He found that sulpho-arseno-benzol gave rise to very little pain when injected intramuscularly.

Dr. MASTERMAN laid stress on the importance of treating congenital syphilis at an early age. The older the child the more intractable the disease tended to become.

Dr. HUDSON considered that notification of stillbirths was an excellent idea. It would materially assist in the antivenereal campaign.

Dr. MACKENZIE warned against placing too much reliance on the Wassermann reaction. The public and a portion of the profession accepted a negative Wassermann as a certificate of cure.

Mr. TURNER, in rising to close the discussion, emphasised three points. The first was the advisability of cultivating the clinical instinct, and of not relying entirely on accessory methods of diagnosis, such as the Wassermann reaction. The second point was the urgent need of early diagnosis and early treatment in dealing with venereal disease. The third the necessity of preserving professional secrecy. When the public was ready to accept compulsory notification such a measure would come. Such a moment had not yet arrived.

After Dr. FINDLAY had replied to the various questions that had been raised the meeting was adjourned.

During the course of the afternoon demonstrations were given in methods employed in the treatment of venereal disease. Dr. J. E. BARNARD demonstrated the use of dark ground illumination in the detection of the *Spirochaeta pallida*. He also showed a method of testing condensers by means of an instrument he had invented for the purpose. Colonel HARRISON discussed the treatment of gonorrhoea in the male, and Dr. RAWLINS gave a demonstration of instruments employed in the treatment of gonorrhoea amongst women. The demonstrations were very well attended.

SECTION OF MEDICAL SOCIOLOGY.

FRIDAY, JULY 1ST.

The Future of Medical Practice.

An illuminating discussion on the Future of Medical Practice took place on July 1st, in the section of Medical Sociology. The views of all sections of medical practitioners were clearly represented; in addition, Dr. T. R. BROWN, of the staff of the Johns Hopkins Hospital, Baltimore, gave the meeting information as to hospital arrangements in the United States, and Mr. Alderman JENKINS enunciated the views of the Labour Party with regard to a whole-time medical service. In opening the discussion,

Sir GEORGE NEWMAN said his task was to organise on behalf of the community a profession whose whole tendency is individualistic; we must not lose that precious quality individualism, hence the "nationalisation" of the medical profession is an impossibility. But profound changes have occurred recently; within

a handful of years the State, in a fit of absence of mind, has in 20 or 30 Acts of Parliament placed statutory duties on individual practitioners; a new relationship must be created between the State and the doctor. The profession is fearful of the imposition of some cast-iron system which might in practice make the medical practitioner servile, dependent, and fettered. To promote a clear and well-established understanding the doctor must acquire a knowledge of the evolution of local government, and the main purposes of the bodies dealing with health, pensions, Poor-law, education, and insurance; the layman, besides specialised knowledge of the work with which he is primarily concerned, should learn as much as he can of professional tradition and sentiment, of the scope and opportunity of voluntary work which touches the profession, and of professional organisations and of their history and relation to each other.

Five outstanding problems now faced the medical profession in its relation to the State.

First, we must find a new unit of health government. In defining the areas of the Poor-law unions, the local sanitary authorities, the local education authorities, the Insurance Committees, and the local War Pensions Committees the country has been mapped out five times over, but the charting has been done by different hands at different times and for different purposes, causing duplication, overlapping, and confusion. Clearly, there would be advantage in having one authority for all health purposes. Another common-sense requirement is uniformity of administration in all comparable areas; all through the country there is need for the adoption of accepted standards and a larger measure of equalisation and uniformity of central and local action. The plan evolved must represent not what the State alone or medicine alone would prefer but the will of the people at present. We require an extension and coördination of medical provision. At present there is inadequacy, unequal provision, and piecemeal effort; we must bring together in proper relation the provision of medical treatment in the home, at the clinic, in the hospital, and in the convalescent home not for the pauper class only, but for the whole of society. A properly connected medical policy will not arrive in our lifetime; all that we can hope to do is to lay some of the foundation stones. The future of the hospital system constitutes another problem with many issues. We have at present no connected hospital system; the relation of hospitals to each other and to the contributory clinics and the insurance system is a typical issue which calls for settlement. A fourth subject, and perhaps the most important of all, is an adequate method of education of the undergraduate and the practitioner. A different kind of doctor is needed in these new times; he requires in addition to the learning and skill of former days an improved training in new subjects, in preventive medicine, and in the political science of communal responsibility. Some specialisation of practice there must be, but we must recognise that such diseases as tuberculosis and venereal and heart disease will never come under control until and unless the general practitioner is in a position to deal with them. Lastly, the medical man of this new age is concerned with the advancement of humanism. The doctor must be the chief educator of the people in the way of health; in being that he cannot escape his share of responsibility in the study and handling of many of the medico-sociological problems which surround us—education, recreation, housing, the conditions of industry, sobriety, cleanness of living, the prevalence of venereal disease, prostitution, the penal laws, the causes of certain crimes, the integrity of family life—all such matters concern us, and to fulfil our vows we must be concerned with them. We cannot be wise healers of the patient or the community without a large sympathy and a liberal humanism. But we must not think that the medical factor is the only or the decisive factor; we must inter-relate medicine with the social, moral, and ethical movements and aspects of man's mind.

Sir WILMOT HERRINGHAM dealt with the problem from the point of view of the consultant. Although it is sometimes said that the advance of the general practitioner is so great that the consultant is no longer necessary, he thought that consultants would not only persist but increase; not only will the growing points of special technical skill and scientific knowledge necessitate fresh classes of consultants, but also there will always be the sage reflection that two heads are better than one, and the desire to satisfy the anxieties of the patient and his friends.

With the advance of medical science the consultant has to consult more persons himself; at present these consultations

are carried out with the maximum of expense to the patient and waste of time of everybody concerned. The poorer patients had the best treatment in the world—that provided by the hospital. Five or six specialists meet in the ward and consider his case; this system works quickly, without friction or much trouble, and the minimum expenditure of time. Contrast this with the nursing home, rarely built for its specific purpose; the other men whose opinion is wanted have either to make a special journey there or the patient has to make an uncomfortable if not painful journey to them. The great need is for some form of institution within the means of the ordinary middle-class patient; the nursing home's charges equal those of a first-class Atlantic liner. The only sound remedy is to extend to private patients the benefit and convenience of treatment at a hospital. Proprietary hospitals run by a doctor with other doctors as employees will not catch on in England. In London there has long been, in Fitzroy Square, a paying hospital financed by laymen which the patients use as they would use a nursing home and where they are attended by the doctor of their own choice and make their own arrangements about fees. At St. Thomas's the paying wards are much on the same system. At King's and Guy's only the staff of the hospital attend the paying patients. The ideal is that the hospital should be the centre of a doctor's life; his home should be in the country and he should journey daily to the hospital and see his patients there, both those who come to consult him as well as the in-patients.

Dr. ALFRED LINNELL spoke from the point of view of a doctor practising in an isolated district. He considered the feeling of the bulk of the general practitioners was so strong against a whole-time medical service that there was no danger of their becoming State servants. The problem of the future of general practice consisted in the proper dove-tailing of a State-controlled service into the general scheme of practice.

In the sphere of preventive medicine the employment of whole-time officers with special training is inevitable, but closer coöperation between these officers and the general practitioners is highly desirable; the latter should be given every opportunity to learn preventive work and be employed at a remunerative wage in any preventive work he is able to undertake. In prenatal work the general practitioner should play an all-important part. For school medical work the whole-time man is more satisfactory from the point of view of administration, but it is hoped that the employment of general practitioners will increase, and no doubt with more experience such a system could be made to work quite smoothly. After the age of 16 the State, through the Insurance Acts, invades the domain of curative medicine in a very decided manner. Although there is room for improvement in certain directions, it would be wise to give the reconstructed panel system a thorough trial. Criticisms of the system are somewhat ungenerous; they fail to recognise that five of the seven years of its working have been war years. All parties seem to unite in condemning the present State system of the medical care of the poor, but it is difficult for Poor-law medical officers of long standing to understand the reasons for this opprobrium. Probably in the future some panel system with free choice of doctor will be adopted in which the local authorities will stand in the relationship of employer.

The relation of the general practitioner to midwifery is rapidly changing; the provision of well-trained subsidised midwives has caused a considerable transfer of normal midwifery from doctors to midwives, but the ideal in a domiciliary service is the association of doctor and midwife in every case, so as to enable the younger doctors to acquire the experience which is necessary if he is to cope with the abnormalities to which he is summoned by the midwife. The provision of maternity homes is an urgent necessity; they make an enormous difference in the comfort of the patient and the doctor. Powerful forces are on our side in getting these homes; the difficulty of obtaining domestic help during the confinement is so great that some provision of this nature must shortly be forthcoming. The rather complicated technique of modern methods of treatment of venereal disease has warranted the establishment of clinics with specially equipped officers in charge, but with increasing equipment of the general practitioner in this respect the necessity for the employment of special officers will probably cease.

As regards tuberculosis the appointment of special officers was probably wise and necessary; they have important consultative and administrative duties to perform. It is on the matter of treatment that difficulty arises; sometimes a doctor is at a loss to know whether he is responsible for treatment or not. He is possibly responsible for certification but not for treatment. He is not kept fully informed of the patient's progress while in the sanatorium. All this could be easily avoided. The "dispensaries" should be

"clinics" for consultative purposes, and at every stage the doctor in attendance should be kept fully informed and made in every way responsible.

The increasing complexity of diagnosis and treatment renders it imperative that greater facilities and better equipment shall be available for the doctor in his battle with disease, while the increasing expense renders some form of organisation an urgent necessity. The associated local health centres proposed should become the general practitioner's spiritual home. Study leave during the early years of practice is urgently necessary; the State should give the financial aid required. The system of assistantship should be further extended and men given an insight into the art of general practice; this would be preferable to systematic teaching in the schools by medical practitioners. State interference in curative medicine means necessarily not only the provision of medical attendance for certain sections of the people with the requisite supervision and control, but also the supply of that organisation of special services, institutional treatment, and post-graduate training for doctors which is at present lacking and can only be provided by the State.

Professor GOWLAND HOPKINS'S address was a plea for personal contact of the laboratory worker and the clinician. Communications between them now are practically limited to the post; the clinician asks a definite question and merely expects the answer, "Yes" or "No." But if they were to meet and think together the possibilities of the laboratory as an aid to diagnosis would develop.

It is remarkable, he said, how largely the use of chemical methods in diagnosis has been confined to mere tests for albumin or sugar in urine. Much earlier information and more discriminating knowledge concerning renal failure can even now be obtained by simultaneous analyses of blood and urine, and on the same lines a better realisation of the significance of this or that case of glycosuria. So also estimations of alveolar carbon-dioxide tension made simultaneously with determinations of the hydrogen-ion concentration or the alkali reserve of the blood are giving fresh precision to knowledge in other diseases without inconvenience to the patient.

How are we to catch the patient to apply these micro-methods of blood analysis? Twenty years ago precautionary visits to the dentist were confined to ladies; it will perhaps be less unthinkable 20 years hence than it would seem to be now for the middle-aged to pay precautionary visits to the doctor on behalf of their kidneys. It is often held that this laboratory work should be concentrated in a few large centres. Dr. Hopkins wished to combat this view strongly; if adopted it would cut off the laboratory worker from the stimulus of real contact with the clinician and clinical material.

Later in the discussion Sir KENNETH GOADBY, who acted as liaison officer during the war between the clinician and the laboratory worker, said that the surgeon and physician were prone to scorn the laboratory in the earlier stages of disease and seek help too late. When both got together we should get team work of the utmost value. If laboratories were established all over the country where the general practitioner could do some work in his spare time, he could guide the laboratory worker, who has a tendency to go off on side issues. In dealing with industrial disease especially does the general practitioner want the help of the laboratory; there are several methods of early diagnosis of lead poisoning available before symptoms are present. If the doctor takes the specimen to the laboratory himself he will ask supplementary questions of the greatest value. To enable us to help the industrial worker the Labour Party must assist in the discipline of its members; when we attempt to collect facts the workmen must help by giving full information.

Mr. E. W. MORRIS, House Governor and Secretary of the London Hospital, said that the present position of the hospitals was the result of self-sacrifice on their part. In the stethoscope days the cost of a bed was £60 a year; owing to the increasing complexity of diagnosis department after department had been opened and the cost in 1914 had gone up to £150 a year. But this was a healthy increase; the present cost, £200 a year, represented an unhealthy increase.

The hospitals were proud of having been able to manage with voluntary support only hitherto, but they were prouder still of being able to do good work and, if necessary, would have to break away from voluntary work alone. £100,000 a year could be collected for a hospital by voluntary subscriptions; £200,000 could not.

Money must be got either from the patients or from the State. The locality of the London Hospital made any proposal to close a part of the hospital and reopen it for paying patients impossible, but each patient should pay what he can afford; he should certainly pay his "hotel" expenses if possible. As regards money from the Government, the London Hospital would put their pride in their pocket and take what they could get, but there is the principle of humanism to be considered. The hard mechanism of the Poor-law infirmary might creep into the hospital; we must not do away with the blessing of giving. But this is a different thing from receiving State help for services rendered. Seventy-five per cent. of the patients in the London Hospital are panel patients. Some of the panel doctors in the vicinity have a panel of 10,000. The hospital gets nothing for this work from the doctor or the patient.

The feeling is changing as regards the payment of the honorary staff. Mr. Morris holds the view that the staff should give their whole time to the hospital. He would divide the beds into groups, and for a period of, say, five years, appoint a whole-time medical officer at £2000 a year, with assistants appointed for one year, the first at £1000 a year, the second at £800, the third at £365. For each unit two resident house men are required and a special secretary to undertake the card-index work; proper laboratory help is also necessary. Such a medical and surgical unit are in existence at the London Hospital. Each has about 70 beds and sees out-patients on two afternoons a week. He would like to see posts found in these units for doctors in general practice; the unit would gain by the information the general practitioner could bring concerning early stages of disease.

Many reforms are wanted in hospital management. Above all, a future must be made for the nurses; at present there are only 12 positions in the country with a salary of £400 a year or more. Half the hospital beds are in the wrong place. The average stay in hospital of a patient is three weeks, two of which could well be spent in a less expensive institution. The war has taught us another lesson; we want a co-ordinating centre so that if a patient cannot be taken into one hospital the friends can learn where he can be admitted. Much of the work done at present is wasteful; chemists are examining samples of drugs, &c., for each hospital separately, whereas this work could easily be done by a common staff.

Alderman C. S. JENKINS expressed the views of the Labour Party. Before the passing of the Insurance Act it was difficult for a workman to get adequate medical attendance; nowadays, when the average wage on which he had to support a family was less than £4 a week, he had very little money to spend on the doctor. The Insurance Act does nothing for women and children. The facts as regards industrial hygiene are appalling; in the boot and shoe industry the average age at death is under forty; 90 per cent. of the deaths are due to respiratory diseases. In the iron and steel trades the average age at death used to be 39, but just before the war the figure had improved to 49. Why should men die at this age? The reason was that flesh and blood are cheap. He agreed that during the war the doctors were overworked, but panel practice was not what it should be. The Labour Party wants the profession to educate workers in the preservation of their health and to study the conditions under which the workers live and work. During the war, when the value of labour was recognised for the first time, the Government set to work to prevent diseases and did good work. Why cannot this work continue? The party are not asking for a whole-time medical service without a *quid pro quo*; they were willing to give the profession the control asked and an adequate wage.

Dr. BROWN (Johns Hopkins Hospital, U.S.A.) spoke on conditions in the United States. The employers there seemed to take more interest in industrial hygiene. The hospital system recognises the middle-class patient. In all hospitals there are public wards with free beds; some of the patients pay the cost of their keep, \$15-17 a week; others paid what they could afford. For private patients the wards are divided by curtains into cubicles; two or three bedded rooms were also provided at slightly higher charges. State-aid provided a certain number of beds which were automatically free; this arrangement works well, but the teaching hospitals had not adopted the system. For private patients grouping of specialists under one roof has been initiated; the consultants worked in adjoining rooms and had a secretary in common.

Dr. GIRDWOOD (St. Andrews Institute) described the system carried out at St. Andrews under Sir James Mackenzie, where a bacteriologist, chemist, and radiologist worked with three panel doctors. Two hours each day were spent on research work on patients selected from the panel patients, who were all seen at the institute. Each member of the staff makes himself *au fait* with a specialty. Research cases are discussed once a week, when provisional diagnoses are made and treatment decided. Continuous notes of the cases are being taken and digested; as time goes on the actual disease will be tracked to its beginnings.

Dr. F. J. BLACKLEY (Bristol) said that more leisure was required if the busy practitioner is to engage in research. A busy evening in the surgery was worth £3-£4 to a doctor; he must be certain that his time, if spent in other ways, would bring him in an equivalent.

Dr. H. B. BRACKENBURY (London) said that the general practitioner was the humaniser whose need had been pointed out; he was also the pivot of the whole system advocated. The consultant, the laboratory, the hospital bed all exist to help the general practitioner. He is the preventer of disease; in the sphere of personal and domestic hygiene he is all-important. He will prevent the need of all these big institutions advocated. He must be a well-educated practitioner and must not be rushed in his work. The pay must be such that he need not see an overwhelming number of patients in order to secure a reasonable income. To obtain this end he would be prepared to accept any arrangement, State or otherwise.

Mr. E. B. TURNER (London) agreed that the doctor who had attended a family throughout a generation did an enormous amount of preventive work; he was given opportunities of stamping out disease in its incipient stages.

Dr. A. FULTON (Nottingham) said that the efficiency of the general practitioner lay in his capacity, his equipment, and his conscience. The State could improve his equipment by providing study-leave, expert advice by consultants, and instruments of precision. You will never get all the patients into hospitals; his (Dr. Fulton's) daily visiting list includes 26-30 patients. The root of the matter lay in the improvement of the conditions under which general practitioners work.

Dr. P. MACDONALD (York) said that although the speakers who opened the discussion were very indefinite as regards actual proposals, it was evident that they were pleading for an assumption by the State of the responsibility for the health of the nation. Although he was enthusiastically in favour of such a proposal, he wished to utter a word of warning. Unless the interference of the State led to a better condition of things any change would be disastrous.

There are three essentials, he said, of a satisfactory State Medical Service. First, the service should be complete. Obviously all the sections of the medical service necessary cannot be established complete at once, but any section dealt with by the State should be dealt with completely. It might, for instance, be possible to set up a State Hospital Service by itself to begin with—and this is, at present, the most important of all medical requirements, but very soon the coördination of all forms of service under the State would certainly be necessary. Second, that the medical profession should have the greatest possible share in the management and control of the service. Third, that provision for the services should be adequate. Unless ample financial provision be made to allow the medical service to be of the very best, then any further interference by the State should be strenuously resisted by the medical profession.

It is doubtful if the politicians have given much thought to the cost of a satisfactory medical service. He has attempted to form an estimate of the cost of a fairly satisfactory medical service for the city of York.

(a) General Practitioners' Service: The cost of the present panel service for this year is about £19,100. To extend this to dependents would multiply the cost by three, making a sum of £57,300.

(b) Hospital service. The expenditure of the York Hospital for 1919 was about £20,000; the hospital serves a larger area than the city, but the amount apportioned to the city is about £13,000. The community, however, needs thrice its present hospital accommodation; the cost would be approximately £40,000, which might be reduced by the establishment of "paying" beds to £32,000. These figures do not include the payment for medical services, an essential with State

control; a minimum amount of £8000 should be allowed for this purpose.

(c) Present State Medical Service, including the activities of the Public Health Department, Poor-law, War Pensions, and mental diseases. Some of this medical work could be handed to the general practitioner and the cost merged in those of the practitioner and hospital services. The public health medical officials are at present underpaid; the present cost of about £37,000 could only be slightly reduced to about £32,500.

(d) The present Poor-law Infirmary (370 beds). The annual cost is approximately £13,000 of which £11,200 is incurred by the city of York. Only about two-thirds of the beds are used; the cost of the beds required might be estimated at £10,000.

(e) Additional Services. The above makes no provision for dental service or the services of such specialists as pathologists, laryngologists, dermatologists, &c. A sum of £7500 might be allotted for this purpose. The sum-total is £147,162 for a population of 80,000; the present cost per head to the State is about 16s.; the increase is about 20s. Working on these figures the cost to the State of a fairly complete medical service for the whole country would be between 70 and 80 million pounds a year, an increase of between 40 and 50 millions on the present cost without including the sum representing interest and sinking fund on capital costs.

From his experience in connexion with the initiation of the panel service Dr. Macdonald is doubtful if the Ministry of Health is prepared to advise the expenditure necessary for the establishment of an efficient service. Any satisfactory solution of this medical problem is impossible as long as this country is run on its present lines; the politician must be replaced by the scientist, who, if he were free to solve the problem of production, could enable the country to earn even the vast amount of money required for our urgent medical and social needs. All we medical sociologists can do at present is to help to promote a public opinion which will bring peace to the world and to influence the politician to give that endowment to science that will bring about increased production.

EXHIBITION OF SURGICAL AND ELECTRICAL APPLIANCES, DRUGS, AND FOODS.

There were things worth seeing at the exhibition held in the Cambridge Corn Exchange; we doubt whether on any previous occasion there has been offered at these meetings a more scientific or attractive presentation of exhibits.

Surgical and electrical apparatus mainly occupied the field, though there was a good show of drugs, including synthetics and improved antiseptic preparations made by our own manufacturers. On the whole, the section comprising foods was dull and without any outstanding features, if we except the attempts made at some of the stalls to convince the visitor that vitamins had been captured. The fine building, with its admirable lighting provision gave the exhibitors ample opportunity for setting forth their exhibits under favourable conditions, and they did so with artistic regard. The stalls were decorated with good taste, and the exhibits were placed in attractive fashion. In beginning the review of some of the principal objects shown we propose to classify the exhibition into the following divisions: I., Surgical Apparatus, including electrical appliances and scientific instruments; II., Drugs, including antiseptics; III., Special Foods; IV., British Spas; and V., Literary Exhibits.

I. Surgical Apparatus, including Electrical Appliances and Scientific Instruments.

The interest of the display of surgical appliances turned largely on the developments arising out of the treatment of injuries and mutilation occasioned by the war. The "P-K" Arm, Ltd., of 8, Southampton-row, London, W.C., showed, for example, mechanical hands and arms described as almost human. The improved types demonstrated are designed specially for manual workers and others who have lost an arm. The successful application of these fittings in the practical affairs of life is remarkable, and shows great ingenuity. The principles underlying the mechanism, together with examples of application, have been described in our columns.¹ The orthopaedic appliances of the Gloucestershire Surgical Appliances Co., of 1, Belle Vue Lawn, London-road, Cheltenham, also deserve notice. The construction of these shows

¹ THE LANCET June 8th, 1918, p. 793.

admirable adaptation where mechanical assistance is called for in bodily deformity, arising from disease, war casualties, and so on. In addition to orthopaedic appliances, Newlums, of 24, South Molton-street, London, W., demonstrated an interesting series of artificial limbs adapted to all amputations. The exhibit included special arms for heavy manual workers and attachments adapted for all occupations. Amongst the special features at the stall of S. Rampling, of 8, Regent-street, Cambridge, was the "Kenney" Featherweight Artificial Leg, described as the lightest leg made, suitable for all amputations, the weight of the limb for above-knee amputation being $4\frac{1}{2}$ lb. An exhibit which attracted great interest was that of Mr. H. Brook, of 8, Parkhurst-road, Sutton, Surrey. Here were models of masks for facial disfigurement, including, amongst other applications, those designed to cover loss of jaw, tongue, and ear. The designs showed great ingenuity, and were studiously inspected by the medical visitors.

Surgeons found in the exhibit of Messrs. John Weiss and Son, Ltd., of 287, Oxford-street, London, W., a profusion of modern instruments which drew their attention. Most of these were well described as new inventions. Another exhibit of up-to-date surgical instruments was that of Messrs. Down Bros., of 21 and 23, St. Thomas-street, London, S.E., the appliances shown giving striking illustration of recent advances. Features of this exhibit were the specimens of aseptic hospital furniture for use in the operation theatres and wards of hospitals. A novel presentation was that of Messrs. Spencer, Heath, and George, Ltd., of 48, 52, 54, Goswell-road, London, E.C., who exhibited examples of their apparatus for carrying out medical gymnastic exercises, designed for the treatment of stiffened joints and weakened muscles. This exhibit proved very attractive in bringing to view useful methods of physical treatment in many directions. The advances in the mechanics of that very important branch of surgery, dentistry, found illustration in the exhibit of the Dental Manufacturing Company, Ltd., of Alston House, Newman-street, London, W., where there was demonstrated a complete equipment for dental supervision and treatment to be used in maternity and child welfare centres, school clinics, and general public service. Amongst a selection of modern surgical instruments, Messrs. Arnold and Sons, of Giltspur-street, London, E.C., showed their latest models of steam and electrically heated high-pressure sterilisers and also an operation table, the important and attractive feature of which is the "Everbrite" metal, a name which explains an obvious claim.

Surgical developments were profusely illustrated on the well-arranged stall of the Surgical Manufacturing Company, of 83 and 85, Mortimer-street, London, W. Here were new examples of guillotines, urethral dilators, ophthalmoscopes, and mention is deserved of the "Surgman" pattern of sphygmomanometer for measuring the maximum systolic blood pressure. This apparatus appears simple in construction, is compact, and an important advantage is that the mercury in the instrument cannot be spilled, a clear drawback to previous designs. The exhibit included a series of sterilisers constructed on scientific lines. As the name implies, the Genito-Urinary Manufacturing Co., Ltd., of 66, Margaret-street, London, W., exhibited a wide selection of genito-urinary instruments, including cystoscopes, urethral dilators, bladder retractors, and so forth, designed by well-known surgeons. Mr. Henry Lewis, of 2, Westmoreland-street, New Cavendish-street, London, W., made a point of deformity appliances, including an unbreakable leg instrument, a splint for the treatment of ununited fractures and trusses adapted for all cases. Messrs. Maw, Son and Sons, Ltd., of 7 to 12, Aldersgate-street, London, E.C., exhibited appliances of surgical interest, including an intestinal retractor (Richardson), useful, it is claimed, when portions of fixed gut deep down in the abdomen have to be sutured or stitches put in the bladder. There was also exhibited a special safety chloroform inhaler, which, amongst other things, pro-

vides against air being pumped in the wrong direction and the possibility of liquid chloroform, as such, being projected. A large assortment of surgical instruments of every description was to be seen at the stall of Messrs. Mayer and Phelps, of Chiron House, 59-61, New Cavendish-street, London, W. These comprised urological, gynaecological, ophthalmic, laryngological, nasal, aural, and anaesthetic appliances. The latter included a "safety-first" chloroform inhaler, as in the previous exhibit, guarding against the risk of ejecting chloroform out of the bottle, and Shipway's improved apparatus for the administration of warm anaesthetic vapours was also shown. The main interest of the visitors in the exhibit of Messrs. Hawksley and Sons, of 357, Oxford-street, London, W., appeared to be centred upon the apparatus associated with heart research work, blood-pressure gauges, and haemocytometers. The instruments shown had the hall-mark on them of well-known pioneers of medical science. A very impressive and artistic exhibit was that of Messrs. Allen and Hanburys, of Plough-court, Lombard-street, E.C. There was here a profusion of surgical requisites and appliances, as well as of fine chemicals.

Electro-medical apparatus was a marked feature of the exhibition, and the developments in X ray outfits—transformers, interrupters, fluorescent screens, and so forth—were of a very interesting character. There was a profusion of apparatus shown also providing currents for galvanism, ionic medication, electrolysis, cautery, sinusoidal current, and faradisation. X Rays, Ltd., of 11, Torrington-place, Gower-street, London, W.C., exhibited a remarkable series of new models of X ray tubes and the electric accessories which their use involves. The new radiator-cooled Coolidge tubes, rectifying their own current, attracted particular attention. With these tubes it is possible to employ a simple high-tension transformer on a main alternating current supply without any mechanical rectifiers.

In addition to radiographic apparatus for general purposes, Messrs. Frederick R. Butt and Co., Ltd., of 60, Conduit-street, Regent-street, London, W., demonstrated a 10-inch coil outfit specially built for dental surgeons, a transformer type of apparatus, and a complete set of accessories for dental radiography. This interesting exhibit included a diathermy apparatus for thermic treatment and surgical operations. The firm, well known in the past as Harry W. Cox and Co., Ltd., has now amalgamated with the Cavendish Electrical Co., Ltd., under the title of the Cox-Cavendish Electrical Co., Ltd., of Twyford Abbey Works, Acton-lane, Harlesden, N.W. They made a special point of their "standard" X ray group, suitable for a large hospital. The important claim is put out that with this group instantaneous radiography may be undertaken, exposures being possible with a gas X ray tube of only a fraction of a second. There should be mentioned also their combined galvanic and faradic switch-table, used on a large scale through the war, which provides the current for galvanism, faradism, and rhythmic interrupted currents. Apparatus for ionic medication, particularly in gynaecology, was shown, special electrodes being designed for the purpose. We have already described the Snook interrupterless machine² made in the workshops of Messrs. Newton and Wright, of 72, Wigmore-street, London, W. The apparatus is described as consisting of a rotary converter with direct current, a closed circuit transformer, and secondary rectifier. It is all enclosed in a cabinet with spark-gap milliamperemeter, and so forth, the whole outfit being under ready control. The exhibit includes a simple X ray plant for dental work and a series of well-proved tubes and accessories.

Modern developments in X ray appliances were well illustrated at the stall of Messrs. Schall and Son, of 71-75, New Cavendish-street, London, W., who claim for their outfit that it can be put together in a compact way, and so improvised as occasion requires. Portable diathermy apparatus for operations in the bladder and local treatment formed part of this interesting exhibit. Besides the well-known "galvanoset"

² THE LANCET, Jan. 30th, 1909, p. 328.

apparatus, a liquid rheostat for ionisation, galvanisation, electrolysis, and so on, the Medical Supply Association, Ltd., of 167-185, Gray's Inn-road, London, W.C., gave an interesting exhibition of Professor Bergonié's apparatus for the treatment of obesity, cardiac derangement, and conditions set up by deficient elimination. There was here, also, an instructive display of surgical appliances, including operating tables. New electro-medical developments were much in evidence at the stall of Messrs. Watson & Sons, of Sunc House, 43, Parker-street, Kingsway, London, W.C. They made a feature of their high tension transformer, described as an outfit complete in cabinet with either rotary converter for direct current supplies or synchronous motor for alternating current supplies, including close circuit transformer, high tension rectifying disc, large milliamperemeter combined with a trolley switch table fitted with resistance and auto-transformer controls. Altogether this was a fine display of up-to-date X ray apparatus, while it included other electro-medical applications and an exhibit of radio-active substances. Amongst the interesting exhibits on the stall of the Cambridge and Paul Instrument Co., Ltd., of Cambridge, was what is described as the Cambridge Electro Cardiograph, the action of which depends upon the variations of the minute electric currents due to the heart's action causing deflections of a fine fibre forming part of the galvanometer. The current variations are recorded photographically, the magnified image of the fibre being projected on to a camera. The exhibit included well designed microtomes and thermometers giving 24-hours records of the patient's temperature.

(To be continued.)

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Australasian Medical Congress.

ARRANGEMENTS for the forthcoming Australasian Medical Congress to be held in Brisbane in the end of August are well forward. Interest will centre in the decision which is to be made as to the future constitution of the Congress. At present it is open to all reputable members of the medical profession who subscribe. It is proposed that henceforth only members of the British Medical Association will be eligible. A ballot paper with a direct question will be furnished to each member of the Congress, whether he be present at Brisbane or not, so that every member who has paid his subscription, will be able to record his vote in favour or in opposition to the proposed change. The result of the voting will be announced at the final meeting of Congress on Saturday, August 28th, 1920. The discussion at the final meeting will depend upon the result of the ballot. Should it be determined that the Congress as it is constituted at present be discontinued, a consideration of arrangements for future combined meetings of the profession will be needed. In this event, the matter will also be referred to the B.M.A.

Criminal Abortion.

The Commissioner of Police in Victoria recently addressed a circular letter to the general hospitals, asking that the members of the staff should communicate at once to the police any instance coming under their notice of a presumed illegal operation. The reason for such a step was said to be the great increase in such operations, and in order to uphold the law two detectives had been detailed to be at the service of the hospitals at any hour. The hospital committees sought the opinion of their staffs, and the question was ultimately brought before the Victoria Branch, B.M.A. The Council of this body sent a deputation to the Commissioner to point out the difficulties surrounding the proposal, but advised the hospital authorities that the matter would be referred to the Federal Committee of the Association for an opinion.

Alien Enemy Practitioners.

Considerable feeling has been displayed in Sydney and in Brisbane in connexion with the attitude of the

Federal authorities towards two practitioners of German origin and training in allowing them to remain in Australia. Both these practitioners were interned during the war, and the contention is that they should have been compulsorily repatriated. The New South Wales branch of the B.M.A. resolved to approach the authorities in the case of Dr. Max Herz, and at a special meeting of the Council of the Victoria branch the following resolution was carried:—

That this Council strongly supports the New South Wales branch in its action regarding interned alien enemy practitioners and in the specific instance of Max Herz.

Personal.

Sir Henry Maudsley is about to retire from active teaching at the Melbourne Hospital. About 1902 he resigned his position as indoor physician at the Alfred Hospital and was elected to a similar post at the Melbourne Hospital, which he has held ever since, being granted leave during his service at the front for four years. At a recent staff dinner Sir Henry Maudsley was presented with a silver token as an expression of the esteem in which he is held by his colleagues. He will join the consulting staff, and will continue to hold his appointment as lecturer on medicine in the University.

The death is announced of Colonel H. W. Bryant, M.R.C.S. Eng., who was a well-known and popular practitioner in Melbourne. Colonel Bryant was one of the first to volunteer for overseas service, and was in charge of field ambulance units and hospitals in the heart-breaking period of disaster in Gallipoli and received mention in despatches for his work. But the strain told on his own health, and he was forced to return to Australia. He was able after a rest to render further valuable aid as a member of referee boards, but never completely regained strength, and died after a lingering illness at the age of 59. The late Colonel Bryant had taken an interest in military medicine for many years before the war, and left Australia with the rank of Lieutenant-Colonel.

HOUSING NOTES.

Remedy for Slums.

THE Special Committee under Mr. Neville Chamberlain, M.P., recently appointed by the Minister of Health to advise him as to the principles to be followed in dealing with unhealthy areas, will shortly issue an interim report dealing specially with London.

The three main impressions so far formed by this Committee are that the problem of the London slums is vast and complex; that it is intimately linked with that of transport and the distribution of houses, offices, and factories; and that any comprehensive reconstruction of slum areas while the housing shortage is so acute is impossible. It is pointed out that 550,000 London people live in unsatisfactory housing conditions, and that nearly two-fifths of this number occupy areas definitely unhealthy. Transport facilities, by not keeping pace with the needs of the growing districts, have added to the difficulties which have compelled labour to remain in the central area, while a constant increase in site values has raised rents; thus the inhabitants have had to measure their accommodation not by their need, but by their purse. Many thousands of houses built for one family are now occupied by two, three, or even more, without any addition to the sanitary conveniences. The condition of working-class houses in London is considerably worse now than before the war, and the combination of overcrowding and deterioration makes the problem of improvement extremely urgent.

Two main alternatives are suggested by way of remedy. The first is to allow the population to expand vertically by building taller houses. This suggestion is regarded by the Committee as quite unsuitable for a working-class population dependent on its own efforts for domestic service and the care of children. Supervision is necessary if the occupants of many-storeyed buildings are not to be at the mercy

of any undesirable tenant and of the spread of infectious disease. Access to playgrounds in the open air is difficult, except by those occupying the lower floors, and construction is no cheaper than that of equivalent accommodation in two-storey cottages. Where such cottages are available, block buildings are left untenanted. The lower floors in high buildings are apt to be sunless; the higher ones bad for women and children. The Committee considers that multi-storey buildings cannot be regarded as making any serious contribution to the solution of the housing problem, and that their erection should be subject to severe restriction both as to height and as to nearness to other buildings.

Redistribution of population.—The second alternative—namely, redistribution of population, the removal of large parts of it bodily elsewhere, rearranging the population left on the old sites with adequate accommodation, and the requisite open spaces—requires time, and must be combined with measures of prevention as well as of cure. No improvement in congested areas can be hoped for if they are allowed to become still more congested by the further demolition of houses to make way for more profitable buildings, and it would seem necessary to discourage any increase of labour-employing establishments in these areas. The Committee is strongly of opinion that side by side with restrictions concerning the slum areas in London there should be encouraged the starting of new industries and the removal of existing factories to garden cities, to contain not more than 50,000 residents, and to be surrounded by a belt of agricultural land. The Committee notes that all past attempts at slum clearance and re-housing have been unconnected with one another and with the problem as a whole. The inter-relation of housing, transport, and industry has not been taken into account. The Committee advocates one general plan for all Greater London, in which exist no fewer than 122 local authorities responsible for housing. A plan should be prepared now which would assign to the various districts their respective functions, so that every reconstruction scheme may conform in its main details to this plan. Further, a body should be set up at the earliest moment with jurisdiction in these matters over an area comprising the Home Counties as well as London. The powers and duties of this body should include: (1) the preparation of a plan for the whole area; (2) general direction of transport development; (3) the adjustment of local finance and rates to bring about an even distribution of the burden among the various local authorities, who would retain their executive powers.

The Committee points out that the effect of slum clearances in the past has often been to push the old inhabitants into adjoining areas which have thus become overcrowded and have eventually degenerated into fresh slums. Where new buildings have been erected in place of those demolished very few of the original occupiers have returned. In six improvement schemes carried out by the London County Council only about 2 per cent. of the displaced population became tenants in the new buildings. "We are not satisfied," says the report, "that any persistent effort has been made to retain these old inhabitants. Generally speaking, we are of opinion that it is wise to avoid sudden change in the conditions and life of the classes under consideration. We believe that the system followed by the late Miss Octavia Hill, by which old houses were carefully repaired and kept under kind but strict supervision might be extended with immense advantage to all concerned pending the possibility of reconstruction." The Committee adds that it does not see how any such extension is to take place under the present system of ownership, and has come to the conclusion that the only way of insuring general improvement is to substitute public for private ownership in unhealthy areas.

PROPOSED EXTENSION OF HAM GREEN HOSPITAL.—Dr. F. R. Seymour, of the Ministry of Health, held an inquiry recently at Bristol in regard to the application of the City Council to borrow £10,605 for the extension of Ham Green Hospital for isolation and tuberculosis cases.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

Hull.—The nutrition of the children attending elementary schools in the city of Hull continues to be satisfactory in spite of the abnormal economic situation in the country. The number of children systematically examined during 1919 in the code groups amounted to 14,920. The state of these children as to nutrition was estimated as normal in 77.6 per cent. and good in 8.2 per cent., only 0.14 per cent. being considered to be actually badly nourished. The average body-weights are slightly above those found in the previous year but the estimates of nutrition, as gauged by the general appearance of the children, are slightly below those of 1918. Dr. James W. Fraser, the school medical officer, alluding to this anomaly, considers it to be due to "substitutes for animal food being used, which increase the weight by fattening, but do not make the firm flesh and pink elastic skin which count for much in the estimation of nutrition." Fat is so much lighter than flesh that the increased weights are perhaps more likely to have been due to increased nitrogenous nutriment than to increase in the fatty food or tissues. Verminous condition of the children, both in body and head, has caused a good deal of trouble, and has necessitated prosecution in several instances; 30 parents were convicted and fined for allowing their children to become verminous after having been cleansed at the corporation cleansing station. Unfortunately, 772 children, who had been found to be verminous at the first examination in 1919, left school during the year without being cleansed. With regard to the employment of children out of school hours (619 boys and 22 girls), most of the boys (384) were employed as errand-boys in various businesses. A curious fact is mentioned in regard to this: "The poverty of the district served by a school does not increase, but diminishes, the employment of children attending that school." The figures are described as the opposite of what might be expected if it were on account of the necessities of the parents that children were sent to work out of school hours, and point rather to the thrift of the parents in the better districts and the thriftlessness of those in the poorer. Physical training is carried out with energy and success. An important advance has been made during 1919 by the institution of a "field afternoon" once a week, this now being the practice in 72 departments; from most departments three classes (about 150 children) attend one of the four public parks, or five other open spaces, so that about 10,800 children enjoy a "field" period of one and a half to two hours every week. Football, cricket, rounders, &c., are included in this phase of physical training. The ailments of the children are cared for at three clinics, where 76,749 attendances were registered during the year, chiefly for "minor ailments," eye cases, ear discharge, and dental trouble. Of ringworm of the head there were 428 cases, and of these 338 were cured, the method of treatment being almost entirely that by ethyl iodide, with an average time, for those who attended regularly, of 8.7 weeks. This is extremely satisfactory, and if maintained will obviate the need for installing an X ray apparatus. In the dental department an increasing number of parents are bringing their children for examination and advice, but more instruction in oral hygiene is needed, both for children and parents. The disease that caused most interruption to school attendance was granular ophthalmia, for which 928 children were excluded; this is a serious complaint, when of long standing, but responds quickly to treatment if taken in time; there is therefore all the more reason, as urged by Dr. Fraser, that every doubtful case of inflamed eyes should be seen by the medical officer as early as possible.

Richmond.—Of the 3763 children on the registers of elementary schools at Richmond (Surrey), 1266 were medically examined at the routine inspections in 1919, as well as 772 specially brought forward for medical

advice, and 627 examined by the school dentist. Of these dental cases 62.6 per cent. were found to need treatment, and 61.8 were treated, which is very satisfactory. No children were found to be suffering from actual malnutrition, and only six were recommended to be kept under observation on this account. There was no definite heart disease or pulmonary tuberculosis. Enlarged tonsils, or adenoids, or both, were referred for treatment in 47 cases, and 112 children were kept under observation. There seems to have been an undue prevalence of ringworm, scabies, and impetigo, not in the code groups, but among the school children generally; but with this exception the health conditions of these children in 1919 appear to have been very satisfactory, and Dr. J. H. Crocker, who presents the report, is to be congratulated on the fact that so many of the children recommended for treatment—viz., 1101 out of 1151—were actually treated.

PRESENTATION TO SIR JOHN MACALISTER.

IN the Barnes Hall of the Royal Society of Medicine the presentation took place, on Wednesday afternoon, of a cheque representing the proceeds of the testimonial fund which had been organised on behalf of Sir John MacAlister. The circular announcing the fund was issued on March 1st to every Fellow of the Society, and time was allowed for those Fellows resident abroad to respond.

Sir HUMPHRY ROLLESTON, the President of the Society, in opening the proceedings, remarked that some men were many-sided and touched humanity at many points, and Sir John MacAlister was a very human man. For that reason he had troops of friends of all kinds and in many lands, and those who were present were there to show their affection for him, for he had a genius for friendship. All knew him as the most unselfish and devoted of men, not only great in sympathy, but prompt, even impulsive, to help. The late Sir William Osler, also with an infinite capacity for friendship, described Sir John MacAlister as "the man who pokes the fire," a simile descriptive of the activity which makes things move and produces results.

Sir ARBUTHNOT LANE, the treasurer of the fund, warmly supported the President's remarks, and hinted at the power wielded by Sir John MacAlister in bringing under the notice of the Government practical suggestions of administrative importance which were generally productive of fruitful development.

Mr. PERCY DUNN, honorary secretary to the fund, referred to the warmth of feeling expressed in the correspondence which he had received. Contributions had come from the United States, Canada, India, East Africa, the Argentine Republic, and from Pekin, 11,500 miles distant. The fund, he stated, had proved very popular among the numerous friends whom Sir John MacAlister had attached to himself.

The PRESIDENT then presented the cheque for £711, the amount, after the deduction of expenses, which the fund had realised.

In reply, Sir JOHN MACALISTER was at first reminiscent. He showed that experience, as resident librarian, in Berners-street, had detached him from medicine, a career which in early life he had intended to follow. He became impressed with the conviction that the old Royal Medical and Chirurgical Society was an entity, capable of vast expansion. So it was that his life and his activities became centred in its progress. It touched him more deeply than he could express to have found so many testifying their kindly feelings towards him, and with the utmost sincerity he desired to thank them all from the bottom of his heart. In his concluding remarks he paid a special tribute to the loyalty and helpfulness of the Society's staff, whose faithful and self-denying services, in their varying capacity, had contributed so much to the advancement of the general interests.

ELECTION OF THE HONORARY STAFF TO A HOSPITAL COMMITTEE.—At a meeting of the subscribers to the Liskeard Cottage Hospital, Cornwall, it was decided that the honorary medical and dental staff should in future be ex-officio members of the committee.

ARMY HUTS FOR CONSUMPTIVES.—At a meeting recently held at Tiverton it was decided to purchase two army huts for tuberculous patients, at an estimated cost of about £500. Sir Ian and Lady Amory have contributed £250 towards the expenditure, and have given permission for the huts to be erected on their land.

Correspondence.

"Audi alteram partem."

THE PELLAGRA OUTBREAK IN EGYPT.

To the Editor of THE LANCET.

SIR,—No greater compliment could have been paid to the work done upon pellagra by Dr. J. I. Enright and myself than the fact that it called forth the long letter from Dr. James Goldberger in your last issue. I have the profoundest admiration for the work of Dr. Goldberger, and I would hesitate to cross swords with such an authority if I did not feel that he, like so many great men, was not infallible.

I was afraid when I read Dr. Enright's paper in manuscript that his statement that the diet-deficiency theory of pellagra was exploded did not quite convey his real meaning. It would appear that what he actually intended was that in the case of the German pellagrins no food deficiency could be traced, though such, he admitted, was found among the Turkish pellagrins. This I tried to make clear in my paper by saying that, though most cases could be explained on the diet-deficiency theory, some undoubtedly could not. To account for this latter group I assumed that something else was in operation, and I adduced that the something else was of the nature of a toxin. Now Dr. Goldberger writes that because of Dr. Enright's cases I was forced into the toxin hypothesis. In part that is the truth. He then endeavours to show that Dr. Enright has not proved his case as to the diet of the German prisoners. That being so, my hypothesis is superfluous.

Dr. Goldberger makes much of the point that Dr. Enright did not clearly state that the German prisoners consumed the diet that was ordered for them. Doubtless Dr. Enright himself will supply the evidence for this, but on a priori grounds the objection is a poor one. Does Dr. Goldberger mean to suggest that the German prisoner would not eat his food because he had had such good diet prior to capture that his food as a prisoner was distasteful, or that the flavouring or cooking was at fault? Surely anybody who has seen the Teuton engaged in the engrossing occupation of eating can but smile at such a suggestion. Dr. Goldberger continues with the argument as follows. Because such a relatively small number of prisoners became pellagrous it cannot be that the diet was at fault, but rather the fault must lie with the man himself for not consuming the food supplied to him. Will Dr. Goldberger explain to me why certain of the prisoners would not eat? The various associated diseases were common to all, so that no argument on these lines is of avail. Surely the only answer is that the prisoners who developed a pellagrous rash did not eat because they did not want to, being in the pre-eruptive stage of the disease; or, having eaten, could not assimilate their food owing to the same cause. I maintain, therefore, that a toxin was at work in these cases.

In this connexion I should like to refer to a case at present under my care. About last Christmas the wife of a professional man suddenly lost all appetite and was unable to eat the food that formerly she had relished. About three months later she developed a typical pellagrous rash. Dr. Goldberger will smile and say, "Exactly—food deficiency followed by pellagra." However, there was no reason whatever for her sudden dislike for food, and I feel certain that she did not eat because she already had pellagra, and not that because she did not eat therefore she became pellagrous. Do the majority of phthisical patients become pellagrous? Do those suffering from carcinoma ventriculi or any other wasting disease show evidence of pellagra? Our experience is utterly against such a view. Any unbiased observer must agree that in many of the cases of pellagra something more than a mere food deficiency is present. This something more, I maintain, is probably a toxin.

Food deficiency explains many cases of pellagra, but not all, and if Dr. Goldberger wishes his splendid work

on this subject to live he should consider the ways in which a diet outwardly sufficient may fail to be assimilated by the patient rather than state, with insufficient evidence, that the patient does not eat the food presented to him.

I am, Sir, yours faithfully,

Liverpool, July 3rd, 1920.

A. DOUGLAS BIGLAND.

THE INVESTIGATION OF RENAL EFFICIENCY.

To the Editor of THE LANCET.

SIR,—Having read with great interest the paper on the Treatment of Nephritis by Dr. H. MacLean and Dr. A. E. Russell in THE LANCET of June 19th, in particular from the point of view of the increasing means of determining the adequacy or inadequacy of the kidneys, which the laboratory places at our disposal, I am anxious to draw attention to an aspect of the problem (as it presents itself to the clinician), which is not touched upon by the authors. It is this: that the body as a whole presents to us an organism, which, in the process of time, has developed a high degree of specialisation—to this organ the elimination of water and carbonic acid, to that organ the elimination of the nitrogen output, certain salts and water, and so forth, but that the specialisation has not been completed, and that other tissues and organs in minor and minimal degrees cover more or less the same functions. Thus there is no doubt that the bowels and the skin (to name these two only) overlap the kidneys functionally more or less, *even in health*; but that *in disease* it is almost certain that their powers of elimination rise in proportion to the renal inefficiency and to an extent which may convert them into adjuvant or compensatory organs of appreciable value. It comes, then, to this: that it does not suffice, in respect of any particular function, to determine the degree of efficiency of a given organ; in other words, to assess its value. We must go further and endeavour to assess the value of the system at large in respect of this same function. This is where we must hope that the laboratories will come to our aid: but it is just here that we realise the complexity of the problem, and that it will be a long time before it can be adequately tackled. Meanwhile, it is here that the clinician comes in, who, eye to eye with his patient, takes a broad view and endeavours to assess the vitality of the man as a whole, his expectation of life, and, while it lasts, his prospect of living to some purpose. Pending the fuller developments of the science of medicine herein lies its art.

I am, Sir, yours faithfully,

HARRINGTON SAINSBURY.

Wimpole-street, W., July 2nd, 1920.

THE TREATMENT OF NEPHRITIS.

To the Editor of THE LANCET.

SIR,—I was much interested in the paper on certain aspects of nephritis by Dr. H. MacLean and Dr. A. E. Russell, which appeared in your issue of June 19th, and I should like to ask the authors one or two questions as to treatment arising out of their very suggestive article.

1. Is the urea treatment advocated for cases of parenchymatous nephritis with oedema of any value in oedema from other causes—e.g., cardiac?

2. In connexion with the impaired excretion of salt in these cases and consequent accumulation in the tissues, have they any experience of or do they recommend a salt-free diet? I remember years ago it had some vogue with certain physicians; I do not know whether it is still advocated. I never saw any marked result from its use myself, though theoretically it should be of great benefit.

3. With regard to the urea-concentration test, Is there any danger, say in a case of interstitial nephritis, of precipitating an attack of uræmia by administering a large dose of urea to a patient who is already suffering from an excess of urea and similar nitrogenous waste products in the blood?

Further enlightenment from the authors on these three points would be of considerable interest to the general practitioner.

I am, Sir, yours faithfully,

Portsmouth, July 4th, 1920.

E. W. DEWEY.

HIBERNATING MOSQUITOES AS CARRIERS OF MALARIA.

To the Editor of THE LANCET.

SIR,—Permit me to thank Dr. C. M. Wenyon for correcting, in THE LANCET of July 3rd, the account of one of his findings on the above subject recorded in my book "Malaria at Home and Abroad." The results of field and laboratory work in Macedonia now communicated by Dr. Wenyon are of great interest in connexion with the occurrence of malarial infections at a time prior to the incidence of the current year's anopheline mosquitoes, and may perhaps be used to explain similar occurrences in England. Most of the infections of local origin in this country happen during August and September, but occasionally infections occur as early as May. These must be due to anophelines (*maculipennis*), which became infected in the previous autumn and lived through the winter; and on p. 91 of my book I mentioned two views relating to the manner in which the malarial parasite might survive in the particular "hibernating" mosquitoes concerned. Having regard to the observations of Dr. Roubaud,¹ who showed in France that sporozoites in the salivary glands of anophelines somewhat quickly degenerate and lose their infecting power, Dr. Wenyon's discovery that in nature the zygote (oöcyst) stage of the parasite retains its vitality in hibernating mosquitoes all through the winter is of great importance. It indicates that the mosquito host plays a less transitory rôle in malarial epidemiology than has been ascribed to it hitherto, and explains satisfactorily the occasional occurrence of malarial infection in the spring.

I am, Sir, yours faithfully,

Symons-street, S.W., July 5th, 1920.

S. P. JAMES.

THE CLINICAL DIAGNOSIS OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In reply to Dr. H. Drinkwater. He confirms his previous position, which I did not misinterpret in my letter, that naked-eye diagnosis is more important than bacteriological examination, and he goes on to say that the latter has always established the accuracy of his clinical observation. I congratulate him, but in an experience of 13 years' work in fever hospitals of 500 beds or more, during eight of which I was responsible for the instruction of students, I have not been so successful, and I say at once that I cannot correctly diagnose diphtheria from the naked-eye appearance of the fauces.

When Dr. Drinkwater describes and illustrates the criteria on which he relies for his own skill, I maintain that exceptions to every one of them are found with some frequency in the practice of a large fever hospital. Even if they were reliable, all the drawings in the world would not enable him to impart such a degree of proficiency to students and post-graduates as would enable them to dispense with or even minimise the importance of bacteriological examination, and in view of the deaths and infections that are known to every M.O.H and fever hospital M.O. to have resulted from the reliance on naked-eye observation, which is even now quite sufficiently prevalent, I regard his teaching as dangerous to the community. Hence my protest.

Only recently in the examination of a large number of children I found diphtheria bacilli in the throats of many in whom definite faucial abnormalities were present, none of which, however, could I discover in Dr. Drinkwater's paper. The patients were removed to isolation hospitals, where the diagnosis was confirmed by independent observation. As regards scarlet fever, does Dr. Drinkwater seriously advocate waiting for the rash before making a diagnosis? What about the cases that have no rash, many of which can be detected by examination of the fauces in the early and most infective stage. My own experience is that some of these present the criteria which he assigns to diphtheria, and I should be sorry for the inmates of the ward to which

¹ Annales de l'Institut Pasteur, vol. xxxii., No. 9, 1918, p. 452.

anyone who thus relied on the naked-eye appearances would presumably admit them. To sum up. I hold clinical and bacteriological diagnosis to be equally essential because one supplies the deficiencies of the other, and that Dr. Drinkwater has not made out a case for the comparative "importance" of the former.

I am, Sir, yours faithfully,

A. KNYVETT GORDON.

Bedford-square, W.C., July 3rd, 1920.

THE ASSESSMENT OF HAND INJURIES.

To the Editor of THE LANCET.

SIR,—In his very interesting remarks on this subject in your issue of July 3rd, Dr. Francis Heatherley mentions that he would have liked a fuller expression of opinion as to the proportional disability of the loss of the hand as compared with amputation higher up the limb. He is quite correct in stating that "amputation of a hand or complete loss of use is a very serious disability and that a lesser assessment on the usual scale compared with amputation higher up is only justified when the man can be fitted with a useful appliance." In dealing with cases under the Workmen's Compensation and Employers' Liability Acts and also under Common Law this very point has to be seriously considered. Under the Ministry of Pensions there is a hard-and-fast schedule which has to be strictly adhered to.

The recognised policy of conservatism as applied to the surgery of the thumb is equally applicable to the forearm and the arm; especially the former. The longer the stump below the elbow the greater the prospect of being fitted with a useful appliance. Just before returning from France I paid a visit to the École Provinciale D'Apprentissage, Charleroi, an institution for the re-education of the disabled, which, it is interesting to note, was founded in 1908. Here was to be seen a man with both hands off. He had been amputated through the right mid-forearm and at the left wrist. With the aid of suitable appliances he was able to work at brushmaking in a most competent manner.

I am in agreement as to the remarks in reference to artificial arms. The more complicated, the less likely to be used. One artificial hand attached to a 5 inch below-the-elbow stump was recently brought to my notice. It was remarkable for its simplicity, as it consisted of a rigid "thumb" with "fingers" having springs at the joints. The man was able to write perfectly when wearing it. In citing this case (a young man of 25, a bricklayer by trade, now no longer able to follow his former occupation) I might repeat a statement I have made elsewhere that "a serious hand injury may be the means of promoting the sufferer from a lower to a higher grade of occupation."

The supreme importance of trying to get adults and elderly men to follow their pre-war occupations (where possible) may be accepted as one of the first principles in dealing with the reconstruction of the disabled.

I am, Sir, yours faithfully,

Royal Hospital-road, S.W., July 3rd, 1920. J. J. SCANLAN.

NOVARSENOBILLON IN THE TREATMENT OF GUINEA-WORM.

To the Editor of THE LANCET.

SIR,—I have been reading in THE LANCET with very great interest letters written about the treatment of guinea-worm with tartar emetic given intravenously. It may be of interest to your readers, and also to the writers of the previous articles, that I have tried treating cases in my hospital here with N.A.B. and have had good results. I started doing this after reading the first letter, giving 0.15 g. N.A.B. with 20 c.cm. cold, sterilised, distilled water. I would be very glad to hear if any of your readers have had the same experience.

I am, Sir, yours faithfully,

CHARLES GEO. GREY,

Captain; Medical Officer.

Ikot-Ekpene, via Port Harcourt, Nigeria, May 24th, 1920.

THE MEDICAL DIRECTORY, 1921.

To the Editor of THE LANCET.

SIR,—The annual inquiry form has been posted to every member of the medical profession whose address is known to us. If the form has failed to reach any practitioner a duplicate copy will be forwarded upon application. Your obedient servants,

THE EDITORS OF THE MEDICAL DIRECTORY.

7, Great Marlborough-street, London, W. 1, July 5th, 1920.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. G. T. Broatch to be Surgeon Rear Admiral. Surgeon Commanders to be Surgeon Captains: A. Gaskell, E. J. Finch, F. J. A. Dalton, E. Sutton, A. R. Bankart, M. L. B. Rodd, H. L. Penny, R. A. Ross, D. W. Hewitt. Lieut. G. C. Angell placed on retired list.

ROYAL NAVAL VOLUNTEER RESERVE.

Temp. Surg. Sub-Lieut. W. G. Robertson's temporary commission terminated.

ARMY MEDICAL SERVICE.

Major and Brevet Lieut.-Col. (temp. Lieut.-Col.) R. B. Ainsworth to be temporary Assistant Director-General, and to retain his temporary rank, vice Major (temp. Lieut.-Col.) A. B. Smallman.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. A. M. MacLaughlin relinquishes the acting rank of Colonel.

Capt. J. Bennet, from Special Reserve, to be Captain.

SPECIAL RESERVE OF OFFICERS.

Capt. W. F. McLean relinquishes his commission and is granted the rank of Lieutenant-Colonel.

Capt. W. F. Wood relinquishes the acting rank of Major.

TERRITORIAL FORCE.

Col. Sir G. T. Beaton, late A.M.O., Lowland Division, Territorial Force, to be Honorary Colonel for the R.A.M.C. Units of the Lowland Division, Territorial Army.

The undermentioned officers to be Deputy Assistant Directors of Medical Services to the Divisions shown against their names: Major F. W. Squair, Highland Division; Major (Brevet Lieut.-Col.) H. A. Leebody, Lowland Division; Major C. J. Martin, Northern Division; Major J. Ward, Home Counties Division.

Major (acting Lieut.-Col.) C. J. Martin relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Capt. R. Eager to be Major.

Capt. G. P. D. Hawker resigns his commission and is granted the rank of Major.

Capt. F. M. Hughes, E. S. Brentnall, G. W. C. Hollist, I. C. Keir, C. E. Anderson, A. N. Crawford, and G. F. White resign their commissions and retain the rank of Captain.

1st Western General Hospital: Capt. (acting Major) T. R. W. Armour relinquishes the acting rank of Major on ceasing to be specially employed.

4th London General Hospital: Capt. E. B. Clayton resigns his commission and retains the rank of Captain.

1st London Sanitary Company: Capt. W. C. Lyons resigns his commission and retains the rank of Captain.

ROYAL AIR FORCE.

Capt. M. C. Breese and H. T. Prys-Jones are transferred to the unemployed list.

INDIAN MEDICAL SERVICE.

The King has approved of the retirement of Major-General H. Hendley.

HOSPITAL SUNDAY FUND.—The following are among the amounts received at the Mansion House up to July 7th, when the total sum from all sources had reached £60,000:—

£4000: The Right Hon. the Lady Stratheona and Mount Royal; £1000: Lloyds Bank, Ltd., and the National Provincial and Union Bank of England, Ltd.; £525: Forestal Land, Timber, and Railways Co., Ltd.; £500: London County, Westminster, and Parr's Bank, Ltd., Chartered Bank of India, Australia, and China, and Hong-Kong and Shanghai Banking Corp.; £315: Watts Watts and Co., Ltd.; £300: Sir A. H. Brown; £262 10s.: Sir John Latta; £210: Blyth Greene, Jourdain, and Co., Ltd.; £200: Anon. Bank of Australasia, Lieut.-Col. More-Nisbett, and Thos. Stevens and Sons, Ltd.; £105: Grace Bros. and Co., W. Gardiner and Co., Ltd., United National Collieries, Ltd., Anglo-Egyptian Bank, Ltd., London and Brazilian Bank, Ltd., British Bank of South America, Ltd., Gas Light and Coke Co., Wilson Sons and Co., Ltd., Amalgamated Industrials, Ltd., M. Isaacs and Sons, Ltd.; £100: Alexander Shipping Co., Ltd., Anon. Albert E. Reed and Co., Ltd., Messrs. Dodwell and Co., Ltd., Messrs. Naumann Gepp and Co., Ltd., Messrs. Matthew Wrightson and Co., Ltd., W. Weddel and Co., Ltd., Voile and Wortley, Imperial Bank of Persia, Miller and Richards, Ltd., Balfour Williamson and Co., W. D. Graham-Menzies, J. A. Roberts, Cannon Brewery Co., Ltd., Pierce Leslie and Co., Ltd., C. Tennant Sons and Co., Ltd.

Obituary.

WILLIAM CRAWFORD GORGAS, K.C.M.G.,
SURGEON-GENERAL, U.S. ARMY.

THE death, after a long illness, of Sir William Gorgas, Surgeon-General of the United States Army, took place on July 3rd at the Queen Alexandra Military Hospital at Millbank. He was the best-known and most uniformly successful medical administrator, not of his age alone but of any age, and his work is comparable only with that recorded of Moses. No sooner were discoveries made tracing an endemic disease to a source removable by rigid hygienic measures than the services of this master-administrator were requisitioned to the farthest quarter of the globe to carry out such measures. And as if by magic—black magic as it appeared to the slovenly, careless inhabitant: white magic to the admiring world outside—the areas were cleansed and freed. But there

was no magic other than that wielded by a strong personality with only one idea in mind—the speedy accomplishment of the work of the moment. Havana, Panama, the Transvaal, the endemic regions of yellow fever in South America, Serbia, are only the best-known sites of his activities. Truly he “let observation, with extensive view, survey mankind from China to Peru,” though negotiations with Peru itself, whose Government attempted in 1919 to procure

WILLIAM CRAWFORD GORGAS,
SURGEON-GENERAL, U.S. ARMY.

his services for a campaign to rid the Republic of yellow fever, malaria, and plague, were then abortive.

William Crawford Gorgas was born at Mobile, Alabama, on Oct. 3rd, 1854, and was the son of General Josiah Gorgas, of the Confederate States Army. He graduated A.B. at the University of the South, Sewanee, Tennessee, and qualified M.D. in 1879 at the Bellevue Hospital Medical College, New York University, where he remained for a year as interne. He was appointed surgeon in the U.S. Army in 1880 and promoted to captain assistant surgeon in 1885, the year of his marriage to Marie Cook, daughter of William Doughty, of Cincinnati, who survives him. His promotion in the service was rapid. He became a surgeon-major and chief sanitary officer of Havana in 1898. In appreciation of his work there he was made colonel, assistant surgeon-general by special Act of Congress in 1903, and surgeon-general, U.S. Army, in 1914. Since 1907 he had been the Permanent Director of the International Health Commission of the Rockefeller Institution, with headquarters at Washington.

The story of the riddance of Havana from the curse of yellow fever has been told often enough, but deserves to be recalled here; for it was typical of Gorgas's work. During the last 45 years of Spanish rule on the island of Cuba the number of deaths from yellow fever occurring annually in the capital, although varying greatly from year to year, was never below 50, and many times exceeded 1000. The work of Major Walter Reed and his colleagues pointed strongly to the prevention of yellow fever being bound up with the destruction of the

mosquito *Culex* (now called *Stegomyia*) *fasciatus*, or the prevention of its bites. Major Gorgas, as he then was, lost no time in putting this theory to a practical trial. As he himself tersely phrased it: “The only infected material from the towns looked after was the sick man, who was carefully sought out and screened from mosquitoes.” Havana was, and remained, in unrestricted communication with half a dozen infected towns; commerce was not interfered with and no restraint was placed upon the admission of clothing or bedding from infected localities; but under a purely anti-mosquito régime, during the year 1901-02 only five deaths from yellow fever were recorded. Seldom has a scientific discovery been applied so promptly and successfully to an administrative problem.

The magnificent Panama experiment followed. Up to the year 1904 the preliminary campaign waged by the American authorities against climate and disease in the Isthmus had sustained a repulse as decisive as it was regrettable. In May, 1905, Colonel Gorgas was freed from the bonds of red tape that fettered him. President Roosevelt, on his own responsibility and without consulting Congress, compelled the Canal Commissioners to resign, and appointed Judge Magoon as Governor of the Canal Zone with powers little short of autocracy. Under Gorgas and Magoon, the known measures against the mosquito were remorselessly put into force. Every house in Panama was disinfected, stringent measures were taken for the early recognition of cases of yellow fever and malaria, and every inhabitant of the city was inspected by a physician once a day. In addition, the breeding-places of mosquitoes were actively treated, water-tanks and cisterns cleaned and covered in, and a pipe-supply installed. This was in May. The last case of yellow fever occurred in Colon on August 27th and in Panama on Sept. 14th. In October Gorgas and Magoon offered a sum of \$50 in gold to any person, not a member of the health department, notifying a case of yellow fever in the Canal Zone. There is no record that any award was made.

In 1913-14, responding to an invitation from the Chamber of Mines at Johannesburg, he made an important investigation into the high death-rate from pneumonia among the native miners on the Rand. Subsequently one of his chief assistants at Panama was offered the post of advisory medical officer to an important group of mines, an appointment which he still holds with excellent results. Two years later found General Gorgas occupied with a survey of the endemic foci of yellow fever in the southern continent of America. During the war he went to Serbia with the Rockefeller Antityphus Mission, and later helped to organise the arrangements for the hygiene of the American Army.

General Gorgas received many official acknowledgements of his work; he was made honorary D.Sc. of several American universities, and, in 1914, of the University of Oxford. The K.C.M.G., his most recent honour, was received from the King personally on June 8th, when he was on his sick-bed.

The reputation of Gorgas as a scientist has been challenged in certain quarters, in view of the fact that he was not responsible for the actual discoveries without which his work could not have been done. For this he needs no defence. Science and art are at their greatest when they join hands, and the man who acts as a link between discovery and its application needs a combination of qualities as rare as those of the pure investigator. It has been too much the pride of the seeker after abstract truth in the exact sciences to care little as to its application. But even when research has been undertaken with the sole aim of finding the cause of an endemic fever or the source of an infection, the successful investigator would often cut a poor figure as the organiser of an expedition to stamp out the scourge in the light of his discoveries. It is not only as a scientist but as a leader of men, as a hero of at least two of the most successful campaigns ever waged, that the name of Gorgas will always be gratefully remembered. The formal procession with the body from Millbank under military escort to St. Paul's, and the ensuing ceremony in the Metropolitan Cathedral, are evidences of the reverence due to a great benefactor of humanity, which in this case are amply called for.

MONTAGU HANDFIELD-JONES, M.D. LOND.,
F.R.C.P. LOND.,

CONSULTING OBSTETRIC SURGEON TO ST. MARY'S HOSPITAL.

Dr. Handfield-Jones, who died on July 2nd at the age of 65 from heart failure, had been in declining health for some time. Born in 1855, he was the eldest son of Dr. Charles Handfield-Jones, F.R.S., and was educated at Rugby and at London University. As a student at St. Mary's Hospital he showed great promise, winning a scholarship in natural science and an exhibition in classics and mathematics. He qualified in 1879 with the L.R.C.P. and M.R.C.S. Eng., and was subsequently appointed assistant surgeon to St. Mary's Hospital and lecturer on midwifery and diseases of women, and later obstetric surgeon, a post which he held up to a few years ago, when he became consulting obstetric surgeon. Four years after qualifying he graduated M.B. at the University of London, taking honours in obstetric medicine, and in the same year became a Member of the Royal College of Physicians of London. He proceeded to the M.D. Lond. in 1886, and became a Fellow of the Royal College of Physicians of London in 1900. Dr. Handfield-Jones examined in midwifery for the Conjoint Board and for the Universities of Cambridge, London, and Manchester. He was consulting obstetric surgeon to the Paddington Dispensary and surgeon to in-patients at the British Lying-in Hospital. He was at one time president of the Obstetrical and Gynecological Section of the Royal Society of Medicine, and at another president of the Harveian Society. In 1895 he delivered the Harveian lectures on the Heart in its Relation to Pregnancy, Parturition, and the Puerperal State.

In Dr. Handfield-Jones the profession has lost an acknowledged leader, and a sound exponent of his particular branch of our science.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Treatment and Training of Disabled Men.

Colonel J. S. BOSTOCK, R.A.M.C., Director of the Treatment-Training Branch of the Medical Services Division of the Ministry of Pensions, gave evidence before the Select Committee of the House of Commons on Pensions on Wednesday, June 30th. Colonel BOSTOCK said that the question whether a man was suitable for training under ordinary industrial conditions under the Ministry of Labour or Ministry of Agriculture, &c., or for a course of concurrent treatment and training under the Ministry of Pensions, was determined by medical examination carried out by a medical referee, or a medical board, or the medical officer of a Ministry of Pensions hospital or clinic. Disabled men of the following classes fell to be dealt with by the Ministry of Pensions: (a) Men requiring treatment such as would interfere with regular attendance at a continuous course of training on ordinary industrial lines; (b) men who were likely to break down or had broken down in training or employment under ordinary industrial conditions; (c) men whose condition necessitated concurrent treatment and training in a convalescent centre; and (d) men whose disability was such as to make it impossible or undesirable for them to be trained or employed in association with ordinary workmen—e.g., cases of severe facial injury, blindness, or deafness. Cases of men who broke down during a course of training under the Ministry of Labour were transferred to the Ministry if the medical referee was of opinion that treatment was needed for a longer period than three weeks. Under existing arrangements the provision of training, which cannot safely be dissociated from treatment, for tuberculous men (not officers) was a matter for the Ministry of Health, the department at present responsible for the treatment of such cases. Cases requiring concurrent treatment and training were, generally speaking, dealt with either in (a) convalescent centres, or (b) orthopaedic, neurasthenic, and other hospitals. Men were eligible for admission to a convalescent centre if they were suffering from a disability attributable to, or aggravated by, service, and were medically certified to be either unfit to follow their pre-war occupations or unable to follow them without diminution of earning capacity. Medical treatment was prescribed by medical officers resident at the centre, and carried out under their supervision. Nursing and massage services were available.

Sick quarters for temporary cases of illness or cases requiring medical observation were provided. The centre also included a dispensary and a large massage room fitted up with modern electrical and other apparatus. The amount of training for which a man was capable was regulated in accordance with his physical ability and was determined by a medical officer. In no case was training carried out at the expense of treatment, which was the primary consideration. The training was in the hands of expert instructors under the supervision of an experienced chief training officer. The training was both theoretical and practical in character. The Treasury had sanctioned the provision of 3300 places in convalescent centres as follows: England, 2500 places; Wales and Scotland, 600 places; Ireland, 200 places. Several of the Ministry's hospitals were equipped with a limited number of workshops in which elementary training of various kinds was given to all cases susceptible of training. The training at these hospitals was mainly of a curative or occupational character, but in some cases it formed the basis of vocational training which was continued as soon as the man was fit to leave hospital, either at a convalescent centre or in a course under the Ministry of Labour. Some of these workshops were in being at the time of the transfer of the hospitals from the War Office; in other cases the training facilities had been provided by the Ministry.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 30TH.

Nurses' Leave in Egypt.

Major BIRCHALL asked the Secretary for War whether there were a number of nurses stationed at the 24th Stationary Hospital, Kantara, Egypt, who had been in Egypt for more than three years without leave and whose contracts had expired; and whether arrangements could be made to bring them home.—Mr. CHURCHILL replied: I have called for a report and will write to the honourable Member as soon as it is received.

Nurses' Pensions in India.

Mr. CAMPBELL asked the Secretary for India if he could state when the revised scale of pensions for officers of the Indian Army departments, lady nurses of Queen Alexandra's Military Nursing Service for India, and for officers of the Royal Indian Marine would be issued.—Mr. MONTAGU replied: The revision of the pensions of the classes referred to is still under consideration, and it is hoped that a decision will be come to shortly.

Scheme for Training Ex-Soldiers.

Mr. LAWSON asked the Minister of Labour whether he would issue a White Paper showing the details of the scheme for training ex-soldiers and setting forth the allowances received by the men at each stage of training.—Dr. MACNAMARA replied: Yes, Sir; I think the suggestion a good one and will forthwith prepare and lay a paper as my honourable friend asks.

Report on Slum Areas.

Lieutenant-Colonel FREMANTLE asked the Minister of Health if and when he would publish the report of the Slum Areas Committee and would say what action he proposed to take on its recommendations.—Dr. ADDISON replied: The interim report of the Committee dealing particularly with the London problem has already been published. The honourable and gallant Member will appreciate that save in so far as reconstruction is possible without material displacement of the population it is unfortunately not practicable to deal on a large scale with slum areas, except in the way of preparing the schemes, until much more progress has been made in providing new houses, which is an additional reason why it is important that the London County Council should press forward with all dispatch with their big housing schemes.

Habitable Houses in London.

Mr. BRIANT asked the Minister of Health if he would state what was the number of empty houses in London fit for habitation at the last available date.—Dr. ADDISON replied: I regret that I am not in a position to give precise information, and I will communicate with my honourable friend in regard to it. I may mention, however, that last year inquiries were made as to empty houses in London and neighbourhood which might be suitable for conversion; that 4300 houses of this kind were considered; that a large number of these houses soon became occupied; and that of the remainder only a small proportion were found to be suitable for conversion.

Colonial Medical Service Report.

Lieutenant-Colonel FREMANTLE asked the Under Secretary for the Colonies if and when he would publish the report of the recent committee appointed to inquire into the conditions of the Colonial Medical Service; and would he say what action he proposed to take on the recommendations of the report.—Lieutenant-Colonel AMERY replied: The com-

mittee referred to has not yet presented its report, and until the Secretary of State has received the report and had an opportunity of considering it, it is not possible to say what action will be taken or whether it will be published.—Lieutenant-Colonel FREMANTLE: When is that report likely to be actually delivered?—Lieutenant-Colonel AMERY: I think it will be very soon. I believe it is being printed at this moment.

THURSDAY, JULY 1ST.

Third London General Hospital.

Sir HENRY HARRIS asked the Minister of Pensions whether the Third London General Hospital, which was to be closed on July 31st, had been offered to the Ministry of Pensions and declined; and whether he would state the number of war pensioners now receiving treatment in civil hospitals.—Mr. MACPHERSON replied: The hospital referred to has been offered to the Ministry, but the accommodation was considered less suitable to the requirements of the Ministry than that of another hospital the transfer of which to the Ministry is being considered. The number of war pensioners now receiving treatment in civil hospitals is approximately 15,000.

Reorganisation of Enfield Cottage Hospital.

Mr. ANEURIN WILLIAMS asked the Secretary to the Treasury whether the trustees of the Enfield Cottage Hospital, the only voluntary hospital in the district, decided last December, in view of its serious financial position, to approve its transfer to the Enfield War Memorial Committee for reorganisation under a new board of management representing the public interests of the whole district; whether this proposed transfer had since then been awaiting the approval of the Charity Commissioners; whether the long delay in completing the transfer was preventing the necessary public appeal for the funds which were so greatly needed; and whether, in view of the very critical situation and the threatened closing of the hospital, the Charity Commissioners would give their sanction to the proposed arrangements without further delay.—Mr. S. BALDWIN replied: The reparation of the scheme for the transfer referred to has been delayed owing to uncertainty as to the intentions of the War Memorial Committee, and to differences of opinion in the locality as to what was required. A scheme has now been drafted, and a print will shortly be in the hands of the War Memorial Committee.

Small-pox in Glasgow.

Mr. ROBERT YOUNG asked the Secretary for Scotland whether any other measures had been taken in Glasgow besides removal to hospital of cases, isolation of contacts, and free vaccination, to deal with the small-pox outbreak; and, if so, what were these measures.—Mr. MUNRO replied: The main additional measures taken by the Public Health Authority of Glasgow are: house-to-house visitation in infected areas; daily visitation of contacts during the incubation period; attention to general sanitation and public cleanliness; disinfection of houses, clothing, and bedding, of cases and contacts; and daily disinfection of tram-cars. In addition, every effort has been made to trace source of infection in every known case.

Medical Examination of Women Pensioners.

Dr. DONALD MURRAY asked the Minister of Pensions whether cases had occurred in which women, on applying for pensions on the ground that they had been deprived of the support of a male relative killed in the war, had been called upon to undergo medical examination in order that their fitness to go out to work might be tested; and, if so, whether he would give instructions for this procedure to be discontinued.—Mr. MACPHERSON replied: My honourable friend probably has in mind those pensions to dependents which are under the Royal Warrant conditional upon the existence of incapacity of self-support through infirmity or age. Where the evidence on this point is open to doubt it is the practice to ask for a medical certificate, which is ordinarily given by the applicant's usual medical attendant. I do not consider that this procedure entails any hardship or calls for revision.—Dr. MURRAY: In the case of a mother whose son contributed to the family exchequer and has been killed, is the policy of the Department to see that the woman is medically examined and certified as fit for work?—Mr. MACPHERSON: My honourable friend is misrepresenting the answer which I gave. There is no desire on the part of the Ministry of Pensions to produce hardship, but in a case where a woman is able to do work my honourable friend will agree that it would be right that we should ask whether she is fit to do work or not. The appropriate way to do that is to ask for a certificate from her own family attendant.

Aged Persons and Sickness Benefit.

Mr. CHARLES EDWARDS asked the Minister of Health whether he would introduce legislation so as to amend the National Insurance Act, 1911, with a view to allowing persons who had been contributors under the Act, and had attained the age of 70 years, having the same benefits of the Act

during sickness as persons who had not attained that age.—Dr. ADDISON replied: The extension of sickness and disablement benefits to persons over 70 years of age would necessitate an increase in the contributions payable by all insured persons throughout the whole period of their insurance, and the only persons who would derive any advantage from such increase would be the very small proportion of insured persons who continue in employment up to or beyond the age of 70. The suggested extension would also involve great administrative difficulties, as in the case of the aged incapacity for work through sickness is not distinguishable from infirmity due merely to old age. The experience of Friendly Societies has shown that the risk in question is not one which can properly be covered by insurance, and provision for the needs of aged persons is already made under the Old-age Pension scheme, in which no consideration of incapacity for work is involved. As at present advised, I do not therefore propose to introduce legislation on the lines suggested by the honourable Member.

MONDAY, JULY 5TH.

Registrars of Births.

Dr. MURRAY asked the Secretary for Scotland whether town councils had power to draw up rules and conditions for the registrars of births, and if they did, under what authority did they act, and what power of enforcement did they possess; and were registrars of births appointed during the pleasure of town councils, or could any condition of this kind be made at the time of the appointment.—Mr. MURRAY (Solicitor-General for Scotland) replied: The powers of town councils in this matter are contained in the Registration of Births, Deaths, and Marriages (Scotland) Acts, 1854 and 1856. These Acts provide for the election of registrars by town councils, regulate the tenure of office, the registrar being removable by the sheriff moved thereto by the town council, or by the Registrar-General, and provide for the remuneration of registrars. Registrars act in the performance of their duties under the direction of the Registrar-General, and are under the general control and superintendence of the sheriff.

TUESDAY, JULY 6TH.

Speed Limit of Motor Vehicles.

Mr. RAPER asked the Secretary for the Home Department if he could now see his way to give instructions for the speed limits on motor vehicles to be increased, in view of the great improvements made in their braking capacity since the introduction of the speed regulations now in force.—Mr. NEAL (Parliamentary Secretary to the Ministry of Transport) replied: An alteration in the maximum speed for motor-cars would require fresh legislation. The whole question of speed limits for motor vehicles generally is within the terms of reference of the Departmental Committee on the Taxation and Regulation of Road Vehicles, and I cannot anticipate their report or the legislation which may follow it.

Tetanus in the Former Wars.

Mr. ROBERT YOUNG asked the Secretary for War if he would state what was the attack-rate and death-rate per 1000 wounded men from tetanus in the South African war, the Russo-Japanese War, the Crimean War, and the Franco-Prussian War.—Mr. CHURCHILL replied: There were 6 cases of tetanus among other ranks wounded or injured in action during the South African War, or an attack-rate of 0.28 per 1000; and 3 deaths, or a death-rate of 0.14 per 1000. There were no cases of tetanus among officers. No statistics regarding tetanus are available in the War Office for the other wars mentioned.

EXTENSION OF THE WINSLEY SANATORIUM.—At the last meeting of the Executive Committee of the Winsley Sanatorium, near Bath, it was decided to extend the building by the addition of 45 extra beds and the provision of a house for the senior resident medical officer. The institution will in the future accommodate 160 patients. The chairman (Alderman H. Anstey) expressed regret at the resignation of Mr. H. W. M. Rees, the medical superintendent, and on behalf of the governors alluded with warm appreciation to his valuable services to the sanatorium.

COMMITTEE ON MEAT INSPECTION.—The Ministry of Health announces the appointment of a committee, with Sir H. C. Monro as chairman, to consider and report on the legislative and administrative measures necessary to secure adequate protection for the health of the people in connexion with the slaughter of animals and distribution of meat for human consumption in England and Wales. The medical members of the committee include Dr. W. J. Howarth and Dr. A. W. J. MacFadden, and Mr. T. Parker, F.R.C.V.S., represents veterinary surgery. Mr. F. H. O. Jerram, of the Ministry of Health, has been appointed secretary, and communications for the committee should be addressed to him at the Ministry of Health, Whitehall, London, S.W. 1.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—A meeting of the Fellows of the College was held on July 1st to elect three members of the Council. Sir George Makins, the President, was in the chair. The result was as follows:—

	Votes.	Plumpers.
Sir Anthony Bowlby	473	9
Sir D'Arcy Power	383	3
F. J. Steward	329	58
W. Thelwall Thomas	240	22
Victor Bonney	190	17
J. H. Fisher	180	28
H. S. Pendlebury	167	11

The President declared that Sir Anthony Bowlby and Sir D'Arcy Power had been re-elected and that Mr. Steward had been elected members of the Council. There were 778 postal votes and 6 Fellows voted in person. Mr. H. J. Price, of Maldon, and Mr. Willmott Evans acted as scrutineers.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination, held on June 24th, 25th, 28th, and 29th, the following candidates were approved:—

Part I., Anatomy and Physiology.—C. C. P. Anning, Cambridge; J. M. Bailey, St. Thomas's; S. C. Bakhle, F. J. Biddle, and W. G. Booth, Guy's; C. Braneld, Leeds; E. T. Brice, Middlesex; V. R. de Boissiere, Guy's; Gertrude Magdalen de Souza, Madras and London Sch. of Med. for Women; W. de Souza, Ceylon Med. Coll.; D. Diamond, St. Bart's; N. L. Eckhoff, Cape Town and Guy's; R. H. Enoch, Cardiff; Gwladys Evans, Cardiff; G. E. Fisher, Guy's; R. D. Flintan, Middlesex; L. Ghabrial, King's Coll.; A. Gordon, P. Hack, P. G. Harvey, and D. B. Hitchings, Guy's; S. J. Hoffman, Cape Town and Middlesex; M. Hongsberger and M. Jackson, Guy's; J. W. Joule, St. Bart's; D. Kostitch, King's Coll.; Catherine Emma Lilian Lendrum, London Sch. of Med. for Women; J. T. Linklater, Cape Town and Guy's; E. Liston, St. Bart's; C. R. McClure, London; L. Mather, Manchester; F. R. L. Miller and C. A. Moody, St. Bart's; A. L. te W. Naudé, St. Thomas's; E. Orsmond, Cape Town and Guy's; W. Parry-Jones, London; R. C. Peate, Middlesex; C. A. Probert, Guy's; F. R. Ratnagar, Bombay and Guy's; B. P. Rees, Middlesex; C. E. Roach-Smith, London; D. G. Robinson, Guy's; C. V. D. Rose, Univ. Coll.; M. Rose, Cape Town and Middlesex; A. B. Rufail, Cairo and King's Coll.; G. S. Sinnatamby, Ceylon Med. Coll.; A. W. L. Smith, Manchester; Betty Stainer, King's Coll.; S. S. Suzman, Guy's; B. M. Toop, London; M. Weinbren, Cape Town and Guy's; and D. B. Whitlock and H. J. F. Wood, Guy's.

Part II., Materia Medica and Pharmacology.—Annie Dorothy Allen, Liverpool; T. J. D. Atteridge, St. Bart's; H. P. Baylis, Guy's; W. Beaumont, London; W. G. Booth and A. Broido, Guy's; N. E. D. Cartledge, St. Bart's; H. V. Croucher, Guy's; A. Downes, St. Bart's; Winifred Phoebe Edmunds, King's Coll.; R. R. Foote, St. Bart's; M. Garfield, Univ. Coll.; J. P. Helliwell, St. Mary's; J. Herbert, Guy's; G. H. Hogben, St. Bart's; S. P. Jacobson, E. I. Liberman, and J. T. Linklater, Guy's; P. M. Lissack, St. Thomas's; S. F. Mina, King's Coll.; J. N. D. Paulson, St. Mary's; E. F. Peck, Liverpool and St. Bart's; T. H. I. Potts, Sheffield; F. L. Rayner, Guy's; R. P. Rees, Middlesex; J. W. Rigby, Sheffield; C. M. Scott, King's Coll.; A. W. L. Smith, Manchester; A. H. Talaat, Middlesex; D. D. C. Thomson, London; A. K. Higgins, Middlesex; C. Woode, Charing Cross; and J. Woolf, St. Thomas's.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful in the subjects indicated:—

DOCTOR OF MEDICINE.

F. A. Bearn, S. L. Heald, N. T. K. Jordan, Harold Sheldon, and J. F. Ward.

FINAL M.B. AND CH.B. EXAMINATION.

Nooman Abddh, K. V. Deakin, Georgiana M. Duthie, F. R. Ferguson (distinction in Surgery and Obstetrics), Evelyn A. Garnett, F. G. Hammett, Joshua Harris, Sylvia K. Hickson, Ernest Jones, F. C. Jones, J. N. Laing, H. A. Lomax, W. E. Mason (first-class honours, distinction in Medicine and Obstetrics), Doris B. Norman, Emily M. Peach, Gerald Sheehan, Constance Snowdon, Annie E. Somerford, G. L. Taylor (distinction in Surgery), Mary I. Turner, F. A. van Coller, and J. B. Wright.

Medicine and Obstetrics.—May Blakiston, J. W. Crawshaw, A. M. El-Aguizy, and Henry Tomlinson.

Surgery.—F. H. Anderson and Percival Fildes.

Medicine.—Irma M. C. Jehansart.

Obstetrics.—H. W. Taylor.

Forensic Medicine and Toxicology.—G. V. Ashcroft (distinction), E. C. Berg, Nancy E. Bleakley (distinction), Muriel Coope, T. E. Coope, Eugenia R. A. Cooper, S. W. Drinkwater, Winifred M. Edghill, T. N. Fisner, Kathleen M. Fullerton, Edward Gleaves, Florence M. A. Graham, W. H. Gratrix, Albert Haworth, Ruth Hill, C. D. Hough, Violet M. Jewson (distinction), Marguerite F. Johnstone, Jessie Kilroe, A. W. Kirkham, R. R. Lane, James Leather, G. H. Lees, Eva G. Le Messurier, W. L. Martland, P. B. Mumford, Terence O'Brien, L. S. Potter, W. E. Powell, Margaret Pownall, Bertha Renshaw, H. L. Sheehan, Florence G. Sherry, Margaret Single, J. W. Smith, Harry Stafford, Doris A. Taylor, S. N. Taylor, Norah M. Walker, Solomon Wand, Sidney Waterworth, Robert Williamson, and J. R. Wright.

THIRD M.B. AND CH.B. EXAMINATION.

Pharmacology, Therapeutics, and Hygiene.—P. D. Abbott, Reginald Anderton, J. H. Appleton, Mary W. Atkinson, Elsie C. Begg, J. B. Bennett, Doris H. Bentham, Benjamin Broman, G. H. Buckley, Vincent Chadwick, E. W. Clough, H. M. Coope, N. S. Craig, O. M. Duthie, Kathleen M. Eastwood, Beatrice L. Ellison, H. E. Emmett, Caroline M. Edwards-Evans, J. H. Fletcher, William Geraghty, Doris M. Hardman, Arthur Ingham, E. L. Jones, Mary Kent, G. L. Meachim, Nora Mills, Winifred H. Mitchell, A. C. Newman, A. A. Pomfret, Hilda Pratt, G. T. Robinson, Abram Rosenstone, Ragheb Salib, Eleanor P. Smith, Henry Southworth, G. B. Stenhouse, J. H. Struthers, Leo Unsworth, Emmeline Wade, C. B. V. Walker, Margaret Wild, S. J. Woodall, James Worthington, and James Yates.

Hygiene.—Margaret Derbyshire, Gwendolen A. G. Edwards-Evans, F. W. W. Fox, C. B. Kirkbride, G. A. Lord, Dorothea A. C. Partington, and Margaret J. Warburton.

DIPLOMA IN DENTISTRY.

Final Examination.—A. L. Craggs, H. B. Ivers, E. B. Manley, V. W. Morse, H. A. Parkinson, Matthew Raeside, and Alice Ramsden.

UNIVERSITY OF LIVERPOOL.—At examinations held recently the following candidates were successful:—

DEGREE OF M.D.

G. H. Darlington, P. E. Gorst, Mary E. Illingworth, Phoebe A. Ince, S. D. McAusland, F. C. Plummer, H. G. Roberts, J. F. Roberts, R. E. Roberts, M. B. Strock, and W. R. Williams.

DEGREES OF M.B. AND CH.B. (HONOURS).

Class I.—W. J. Birchall (with distinction in Obstetrics and Medicine).

FINAL EXAMINATION FOR M.B. AND CH.B. DEGREES.

Part I., Pathology.—J. L. Armour, A. V. Campbell, C. H. R. Carnichael, E. N. Chamberlain, Florence M. E. Davies, Helen M. Duvall, F. H. Edwards, M. H. Finegan, W. M. Frazer, P. R. Howe (with distinction), A. R. Jones, R. M. Jones, C. L. Kopeland, Beatrice M. Niven, and C. Voigt.

Part II., Forensic Medicine, Toxicology, and Public Health.—O. A. Akjaly, F. H. Alexander, *† G. P. F. Allen, *† J. L. Armour, *† J. R. Bhatia, J. S. Bradshaw, † Doris Brown, † W. E. A. Burton, † Doris M. Cassidy, † Mildred M. Clegg, * R. W. Cowie, A. C. Crawford, † Gladys W. Darlington, † I. S. Fox, † W. M. Frazer, † G. L. Gately, W. S. Gilmour, J. Goldberg, *† S. B. Herd, G. M. Hughes, Isabel E. Imison, E. W. Johnson, Isabel K. Johnstone, * R. J. Jones, Irene E. Kenworthy, A. Livingston, F. Q. McKeown, H. R. Madan, † R. F. J. Martin, † J. H. Moorhouse, M. Newman, † J. B. Oldham, † G. W. Phillips, † Kathleen M. Platt, J. H. Pottinger, † A. McK. Reid, J. K. Reid, † T. R. Robertson, Gladys Rutherford, C. F. H. Sergeant, F. C. H. Sergeant, S. G. Sheir, *† S. S. Shrikant, W. T. de V. Thomson, * L. F. Unsworth, *† S. V. Unsworth, † C. A. Wells, and *† T. A. Williams.

* With distinction in Forensic Medicine and Toxicology.

† With distinction in Public Health.

Part III., Medicine, Surgery, and Midwifery.—Esther Ashworth, Evelyn F. Bebbington, G. N. Campey, J. Flanagan, R. O. Jones, T. M. Jones, D. M. Mather, Annie A. Muir, G. H. Potter, Edith M. Seward, Marguerite G. Sheldon, Nellie Wall, and D. O. Williams.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At examinations held recently the following candidates were successful:—

THIRD EXAMINATION FOR DEGREE OF BACHELOR OF MEDICINE.

Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology.

—Sarah Bruce Allan, Alan Angus, Siegfried Annecke, Thomas Henry Bates, Hugh Moray Sutherland Blair, Cecil Colville Carr, Evangeline Carse, James Ferens Coltman, Roy Neville Craig, Walter Nigel Crowe, Richard Leslie Dagger, Robert Alexander McKinnel Dickson, Edgar Reginald Dingle, Hubert Breffitt Leaster Dixon, Giles Arthur Michael Hall, Geoffrey Arthur Haydock, Reginald Hickey, Rev. Eustace Vernon Howard, Leonard Hunter, Ella Keidan, Elizabeth Killian, Mona Kirkhouse, Hilda Lodge, Ettie Ormsby McCullagh, Mary Josephine McManus, Abraham Jacob Moskow, Una Mary Mulvany (second-class honours), Peter Murphy, Patrick Joseph O'Connell, Leo Norton Knight O'Neill, Frederick William Markham Pratt, Jacob Victor Reuben, Adèle Constance Robson, Jessie Evelyn Sheret, George Wilson Spark, Gladys Stableforth, Thomas Synnington Storey, Weldon Patrick Tyrone Watts, James Whillis, George Wilson, and Henry Arthur Wilson.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

THIRD EXAMINATION FOR DEGREE OF B.D.S.

George Norman Season.

THIRD EXAMINATION FOR DIPLOMA IN DENTAL SURGERY.

William Bayly, Leslie Clifford Bodey, Evan Elwyn Lewis, and John Christopher Leslie Phillips.

UNIVERSITY OF ST. ANDREWS.—At examinations held recently the following candidates were successful in the subjects indicated:—

THIRD PROFESSIONAL EXAMINATION FOR DEGREES OF M.B., CH.B.

Materia Medica.

—James C. Anderson, Archibald J. Campbell, Cora C. Campbell, David A. H. Cassells, David C. Clark, George R. M. Cordiner, James Craigie, William M. Cumming, Jean M. Davidson, Violet C. Dobbie, William S. D. Elder, Ruby N. Foggie, Charles R. Henderson, Mary M. Jack, William L. Kinnear, Norah M. Lindberg, Annie T. McDonald, Norman McLeod, Jeannie H. Morton, Margaret C. Muir, Janet L. A. Muirhead, Robert Norrie, Sydney S. Oglvie, John E. Overstead, Alan Pride, Alexander B. Richardson,

Nora A. M. Rodger, Agnes T. H. Shepherd, Lucy C. Simpson, Bhagwant Singh, Edith M. D. Smith, Janet O. Stephen, Arthur K. Tateson, Frances H. Watson, and Thomas Wilson.

Pathology.—Frank E. Anderson, James C. Anderson, Cora C. Campbell, David A. K. Cassells, David C. Clark, George R. M. Cordiner, James Craigie, William M. Cumming, Jean M. Davidson, Violet C. Dobbie, William S. D. Elder, Rubie N. Foggie, Pennel C. Grant, Charles R. Henderson, Mary M. Jack, William L. Kinnear, Norah M. Lindberg, Norman McLeod, Jeannie H. Morton, Margaret C. Muir, Janet L. A. Muirhead, Robert Norrie, Sydney S. Ogilvie, Alan Pride, Alexander R. Richardson, Nora A. M. Rodger, Agnes H. T. Shepherd, Lucy C. Simpson, Bhagwant Singh, Edith M. D. Smith, Arthur K. Tateson, William Thomson, William L. Tullis, Frances H. Watson, and Thomas Wilson.

Medical Jurisprudence and Public Health.—George G. Buchanan, Thomas K. Buchanan, Katharine M. Campbell, Georgina S. Craig, David W. Dawson, William S. D. Elder, Vyvyan S. Ewing, Harry Fisher, Phyllis Fleming, Annie A. Fulton, Alexander H. Harkens, Lazarus Jacobs, Isabella D. Kilgour, Nona S. Lesslie, Katharine D. Macfarlane, Elizabeth W. MacVicar, Isobel M. Mansie, John E. Overstead, Ronald S. Paton, John D. Stewart, Christina J. Thomson, Margaret L. Tod, William L. Tullis, and Margaret H. R. Young.

FOURTH PROFESSIONAL EXAMINATION FOR DEGREES OF M.B., CH.B.

Medicine.—Bessie M. Davidson, Mary Ellison, Frances L. Knipe, Margherita M. Lilley, Christian E. Little, John B. Macdonald, George J. Murray, William G. Robertson, Myles M. Stewart, Eleanor C. Thistlethwaite, Amelia M. Thoms, and Olive M. Whyte.

Surgery.—Bessie M. Davidson, Mary Ellison, Christian E. Little, William G. Robertson, Myles M. Stewart, Eleanor C. Thistlethwaite, Amelia M. Thoms, and Olive M. Whyte.

Midwifery.—Bessie M. Davidson, Mary Ellison, Frances L. Knipe, Margherita M. Lilley, John B. Macdonald, William G. Robertson, Myles M. Stewart, Eleanor C. Thistlethwaite, Amelia M. Thoms, and Olive M. Whyte.

THE price of Colonel L. W. Harrison's "Manual of Venereal Diseases," published by the Oxford Medical Publications, is 16s. net, and not as given in our issue of June 19th.

THE ELIZABETH GARRETT ANDERSON HOSPITAL.—The sum of £50,000 for the endowment of 50 beds at this hospital has now been acquired, and the services of Lady Hall, the chairman of the Appeal Committee, have been commemorated in the naming of one of the wards of the hospital now to be called the Sophy Hall Ward.

RONTGEN SOCIETY.—A special meeting of this society will be held on Thursday, July 15th, at 9 p.m., at University College, Gower-street, London, W.C., when an address will be delivered by Dr. W. D. Coolidge, of the Research Laboratories, General Electric Company, Schenectady, New York. Members of medical and scientific societies are invited to attend.

LONDON HOSPITAL MEDICAL UNIT.—A course of 12 lectures on neurology, open to students and graduates of the London Hospital and other schools, is being given on Tuesdays and Wednesdays from July 13th to August 18th at 2 p.m. in the clinical theatre of the London Hospital by Dr. Theodore Thompson, physician to the hospital, and Dr. George Riddoch, of the Medical Unit. The subjects will be announced in our medical diary.

A Summer School of Civics will be held at High Wycombe from July 31st to August 14th. Particular attention will be given to the needs of teachers of civics and of social workers in health and educational movements. Special courses will be provided on the welfare of infants and young children and experiments in the use of leisure. The lecturers will be Dr. Eric Pritchard, Miss Margaret Macmillan, Mr. Wilfred Buckley, Miss Norah March, and Mr. F. H. Haywood. Full particulars may be had from the secretary, Summer School of Civics, Leplay House, 65, Belgrave-road, London, S.W.1.

A SPECIAL post-graduate course will be held at the North-East London Post-Graduate College, Prince of Wales's General Hospital, Tottenham, N., in connexion with the Fellowship of Medicine and Post-Graduate Medical Association, from July 19th to 31st. The fee for the course, to those not Members of the Fellowship of Medicine, is 3 guineas, or 2 guineas for either week. Names of those wishing to attend should be sent not later than July 15th to the Dean at the Hospital (or at 19A, Cavendish-square, W. 1), or to the Secretary of the Fellowship of Medicine at 1, Wimpole-street, London, W. 1.

ITALIAN CONGRESS OF MEDICAL RADIOLOGY.—A Congress under the auspices of the Società Italiana di Radiologia Medica will be held from Oct. 28th to 30th at the R. Istituto di Elettroterapia e Radiologia Medica al Policlinico Umberto I., Rome. Professor Francesco Ghilarducci will preside over the Congress and the secretaries are Dr. Eugenio Milani and Dr. Sordello Aitilij. Those who intend to participate are asked to communicate with the secretaries at the address of the Congress before Sept. 15th.

PUBLIC MEDICAL SALARIES IN SOUTHAMPTON.—A combined meeting of members of the Southampton British Medical Association, Medico-Political Union, Medical Society, Public Medical Service, Local Medical and Panel Committees was held at the Royal South Hants and Southampton Hospital on Wednesday, June 23rd, and was largely attended. The meeting was called for the purpose of discussing the remuneration paid to public medical officials in the borough. Strong comment was made on the totally inadequate salaries which the meeting considered were being paid to the medical officers working for the Southampton Borough Council, and it was unanimously resolved to send a letter to the Council asking for an increase in the salaries by at least 50 per cent. on the following grounds:—

1. The great depreciation in the value of money and the increased cost of living.
2. The increasing importance and responsibility of their work.
3. Fees in other branches of medical work have been raised from 50 to 100 per cent.—e.g., panel practitioners, Seamen's National Insurance, National Deposit Friendly Society, &c.
4. Many other Councils pay better salaries to their medical officers than Southampton does.
5. The remuneration of officials in other professions has been raised.
6. Your medical officers have no pensions, and unless their salaries are sufficient to allow them to save they will have nothing to live on when they retire.

The letter points out that owing to the increase in the number of junior posts in the public health service only a small percentage of men can expect to attain to the position of principal medical officer of health, and unless salaries are raised very materially this is bound eventually to cause a diminution in the number of men and women entering the service, with consequent loss of efficiency.

CONGRESS OF THE ROYAL SANITARY INSTITUTE.—This Congress will be held in Birmingham from July 19th to 24th, under the presidency of Lord Astor, Secretary to the Ministry of Health, who will deliver the inaugural address at the Birmingham and Midland Institute on July 19th at 8 p.m. Besides the sectional meetings and conferences special lectures will be delivered by Sir Frederick Mott and Dr. Andrew Balfour. At the Birmingham and Midland Institute Sir Frederick Mott will lecture on Body and Mind on July 20th, at 8 p.m., when Dr. C. Grant Robertson will preside. Dr. Andrew Balfour will give a popular lecture, illustrated by lantern slides, on Links with the Tropics, at the same Institute, at 7.30 p.m. on July 22nd. The Section of Sanitary Science and Preventive Medicine will meet on July 20th and 21st, under the presidency of Sir Robert H. Firth, and the subjects to be discussed include Mental Defectives, Production of Clean Milk, the Falling Birth-rate, Malaria, Disinfectants, Influenza, Pneumonia and Allied Epidemics. The Section of Engineering and Architecture—over which Mr. W. E. Riley, late superintending architect to the London County Council, will preside—will be devoted mainly to discussions on Housing, Urban and Rural, Reconstruction of Slums, School Buildings, House Drainage, and River Pollution, and will meet on July 22nd and 23rd. The Section of Hygiene of Maternity and Child Welfare will be presided over by Lieutenant-Colonel F. E. Fremantle, and will deal with the Still-birth Problem, Teaching of Sex Hygiene, Infant Welfare Work, and Recreation of Children. This section will meet on July 22nd and 23rd. Councillor Mrs. George Cadbury will preside over the Section of Personal and Domestic Hygiene, which will meet on July 21st, and will consider Choice and Storage of Foods, Child Hygiene and Physical Culture. The Section of Industrial Hygiene, under the presidency of Mr. Neville Chamberlain, M.P., will discuss Industrial Efficiency and Fatigue, Welfare Work in Factories, and the Health of Seamen. Technical conferences have been arranged in connexion with the Congress, and will include meetings of (1) representatives of sanitary authorities, (2) medical officers of health, (3) engineers and surveyors to county and other sanitary authorities, (4) veterinary inspectors, (5) sanitary inspectors, (6) health visitors, (7) rat officers. All sectional meetings and conferences will be held at the University of Birmingham. A health exhibition will be held at Bingley Hall in connexion with the Congress, where the work of the Birmingham Corporation departments is to be illustrated. Delegates are expected from public departments in England, Scotland, and the overseas dominions, from Denmark, France, Holland, Sweden, and from some 600 English boroughs. Fellows, Members, and Associates of the Institute will be supplied with tickets for the Congress on application to the secretary, and tickets will be obtainable at a reception room at the Town Hall, Birmingham, during the meeting. Those not connected with the Institute can obtain Congress tickets (£1 1s., ladies' tickets, 10s. 6d. each) up to Friday, July 16th, at the offices of the Institute, 90, Buckingham Palace-road, London, S.W.1., and after July 17th in a reception room in the Town Hall.

TYPHUS IN EASTERN EUROPE.—With the support and cooperation of the Secretariat of the League of Nations a Chadwick public lecture on "Health Conditions in Eastern Europe—Typhus a Serious Menace," will be given on Thursday, July 15th, at 5.15 p.m., by Dr. Norman White, Medical Officer of the Ministry of Health, acting as Medical Commissioner, Typhus Commission, League of Nations, in the Large Hall of the Surveyors' Institution, 12, Great George-street, Westminster, Sir William J. Collins in the chair.

The British Orthopædic Association has unanimously elected King Manuel an honorary member in acknowledgment of his great services to the wounded soldier during the war, especially in the establishment of curative workshops in the special military surgical centres.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—The annual meeting will be held at 11, Chandos-street, Cavendish-square, W., on Tuesday, July 27th, at 3 p.m. The annual report and balance-sheet will be received, the election of corporate members confirmed, and the officers and executive council for the ensuing year will be chosen. At the general meeting the work of the federation will be reviewed. The need for constructive effort by the medical and allied professions in the reorganisation of the medical services of the country will be emphasised by speakers among whom will be Lord Dawson and Captain W. E. Elliot, M.P.

WEST AFRICAN MEDICAL STAFF.—The following new scale of salaries has been approved:—

Medical Officers: Commencing salary £660, rising by £30 annually to £720, then, subject to confirmation of probationary appointment £720, by £40 to £960, with "proficiency pay" of £72 a year drawn while in the Colony. Free quarters are provided and free passages as at present. Before proceeding beyond £800 officers are required to undergo an approved course of post-graduate instruction.

Senior Medical Officers: £1000, by £50 to £1150, with £100 proficiency pay. Medical officers who have served for three years at the maximum of the lower grade may, if recommended, draw salary as Senior Medical Officers.

Provincial Medical Officers: £1200, plus £240 duty allowance.

Deputy Principal Medical Officers: £1300, plus £260 duty allowance.

Principal Medical Officers: £1500, plus £300 duty allowance.

Director of Medical and Sanitary Services Nigeria: £1700, plus £340 duty allowance.

Sanitary Officers: £1050, by £50 to £1200, plus £210 duty allowance.

Senior Sanitary Officers: £1300, plus £260 duty allowance.

URBAN VITAL STATISTICS.

(Week ended July 3rd, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had declined from 13.8 to 10.1 in the seven preceding weeks, further fell to 9.9 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 9.0, or 1.3 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 1.1 in Eastbourne, 2.5 in Acton, and 5.2 in Ilford, to 15.6 in Gillingham, 17.3 in Aberdeen, and 20.0 in Blackpool. The principal epidemic diseases caused 233 deaths, which corresponded to an annual rate of 0.7 per 1000, and comprised 88 from infantile diarrhoea, 50 from measles, 45 from diphtheria, 40 from whooping-cough, 8 from scarlet fever, and 2 from enteric fever. Measles caused a death-rate of 2.4 in Leicester and 3.0 in Wigan, but the mortality from the remaining diseases showed no marked excess in any of the towns. There were 1705 cases of scarlet fever, 1603 of diphtheria, and 3 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1646, 1668, and 3 respectively at the end of the previous week. The causes of 21 of the 3391 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham and 3 in Liverpool.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 12.7, 13.3, and 11.5 in the three preceding weeks, further fell to 11.1 per 1000. The 254 deaths in Glasgow corresponded to an annual rate of 11.9 per 1000, and included 9 from infantile diarrhoea, 5 from measles, 3 from small-pox, and 2 each from whooping-cough and diphtheria. The 63 deaths in Edinburgh were equal to a rate of 9.6 per 1000, and included a fatal case of infantile diarrhoea.

Irish Towns.—The 106 deaths in Dublin corresponded to an annual rate of 13.3, or 1.3 per 1000 below that recorded in the previous week, and included 3 from infantile diarrhoea, 2 each from measles and whooping-cough, and 1 from diphtheria. The 98 deaths in Belfast were equal to a rate of 12.4 per 1000, and included 3 from infantile diarrhoea and 2 from whooping-cough.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MEETINGS OF SECTIONS.

Thursday, July 15th.

DERMATOLOGY (Hon. Secretary—Henry MacCormac): at 5 p.m.
Cases (at 4.30 p.m.):
Dr. Bunch: (1) Pemphigus; (2) Urticaria Pigmentosa.
Dr. Sequeira and Dr. Willcocks: Case for Diagnosis.
Dr. O'Donovan: Dermatitis from Acarine Parasite in Discarded Figs.

SOCIETY FOR THE STUDY OF INEBRIETY, in the Rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W.

TUESDAY, July 13th.—4 p.m., Discussion on Alcohol and Alcoholism in Relation to Venereal Disease, opened by Mr. A. Evans.

SEAMEN'S HOSPITAL SOCIETY, at the London School of Tropical Medicine, Endsleigh-gardens, N.W.

WEDNESDAY, July 14th.—2 p.m., Lecture:—Col. S. P. James: Prevention of Malaria.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, W. (by permission of the Royal Society of Medicine).

Short Film Demonstration illustrating Post-Graduate Teaching in Medicine, Surgery and its Specialties will be given on July 12th, by the Fellowship of Medicine, in conjunction with the British Film Institute. Open to all members of the Medical Profession.

MONDAY, July 12th.—5.30 p.m., (1) Dr. Howard Lilienthal: Splenectomy for Banti's Disease. (2) Dr. Charles H. Peck: Thyroidectomy. (3) Dr. Howard Lilienthal: Gastrectomy.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

A Course of Twelve Lectures on Neurology, open to Students and Graduates of the London Hospital and other Schools—

TUESDAY, July 13th.—2 p.m., Lecture I.—Mr. Riddoch: Disorders of Function from Lesions of the Pyramidal Tract.

WEDNESDAY.—2 p.m., Lecture II.—Dr. Thompson: Causes and Treatment of Hemiplegia.

SURGICAL UNIT, in the Units' Lecture Theatre, London Hospital, E.

Special Course of Lectures open to both Students and Post-Graduates.

Two Lectures on Coli Infection of the Kidney—

WEDNESDAY, July 14th.—4 p.m., Lecture I.—Mr. F. Kidd.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 12th.—2 p.m., Mr. D. Armour: Operations. 2.30 p.m., Dr. A. Saunders: Visit to Medical Wards.

TUESDAY.—2 p.m., Dr. Burnford: Visit to Medical Wards. 2.30 p.m., Mr. T. Gray: Operations.

WEDNESDAY.—2 p.m., Mr. D. Armour: Visit to Surgical Wards. 2.30 p.m., Mr. Addison: Operations.

THURSDAY.—2 p.m., Mr. D. Armour: Operations. 2.30 p.m., Dr. A. Saunders: Visit to Medical Wards.

FRIDAY.—10 a.m., Dr. Robinson: Gynaecological Operations. 2.30 p.m., Mr. T. Gray: Operations.

SATURDAY.—2 p.m., Dr. Beddard: Visit to Medical Wards.

Daily.—10 a.m., Ward Visits. 2 p.m., In-patient Clinics and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 12th.—2.30 p.m., Mr. J. B. Banister: Gynaecological.

TUESDAY.—9.45 a.m., Lieut.-Col. R. H. Elliot: Selected Eye Cases and Operations. 2.30 p.m., Mr. C. H. Hayton: Laryngological; Dr. J. Metcalfe: Radiology.

WEDNESDAY.—2.30 p.m., Dr. W. J. Oliver: Dermatological.

THURSDAY.—2.30 p.m., Mr. N. Fleming: Ophthalmological. Dr. J. Metcalfe: Radiology.

FRIDAY.—2.30 p.m., Dr. C. E. Sundell: Diseases of Children.

SATURDAY.—3 p.m., Mr. H. W. Carson: Selected Surgical Cases.

Daily.—2.30 p.m., Operations, Medical and Surgical Clinics, &c.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, July 12th, WEDNESDAY, AND FRIDAY.—5 p.m., Dr. C. Russ: Demonstration of the Treatment of Gonorrhoea by Electrolysis.

CANCER HOSPITAL, Fulham-road, S.W.

Clinical Lectures on the Diagnosis and Treatment of Cancer.

TUESDAY, July 13th.—4.30 p.m., Mr. C. Ryall: Cancer of the Tongue.

FRIDAY.—4.30 p.m., Mr. C. Joll: Cancer of the Thyroid.

CHADWICK PUBLIC LECTURE, in the Large Hall of the Surveyors' Institution, 12, Great George-street, Westminster, S.W.

THURSDAY, July 15th.—5.15 p.m., Dr. N. White, C.I.E.: Health Conditions in Eastern Europe—Typhus a Serious Menace.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street (behind Whitworth Park).

THURSDAY, July 15th.—4.30 p.m., Dr. A. C. Magian: Chronic Uterine Complaints.

A CORNISH CENTENARIAN.—Mr. E. T. Pearce, of Exevill Farm, near Callington, attained the age of 105 years on May 24th.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BURNELL, A., has been appointed Medical Officer for the St. Clement and St. Mary District (Cornwall).

HOLMES, A. H., M.D., Honorary Physician to Ancoats Hospital, Manchester.

MOODY, L. M., M.D. Lond., Bacteriologist and Pathologist to the Medical Department of the Government of Jamaica.

SCALES, F. S., M.D. Camb., University Lecturer in Medical Radiology and Electrology, Cambridge.

King's College Hospital: BICKERTON, J. M., M.R.C.S., L.R.C.P. Lond., Senior Casualty Officer; JOHNS, L. P., M.R.C.S., L.R.C.P. Lond., Second Casualty Officer; PLAYFAIR, K., M.R.C.S., L.R.C.P. Lond., Junior Casualty Officer; RICHARDS, H. A., M.R.C.S., L.R.C.P. Lond., House Anaesthetist; DAVIDSON, A. N. M., M.R.C.S., L.R.C.P. Lond., YOLLAND, R. H., MATTHEWS, W. F., House Physicians; BANES, C. D., M.B., B.S. Lond., ROBERTS, O. W., M.R.C.S., L.R.C.P. Lond., REBURN, H. E., M.B., B.S. Lond., FOULKES, R. K., M.R.C.S., L.R.C.P. Lond., LAWRENCE, R. D., M.B., B.Ch. Aberd., House Surgeons; BANES, C. D., M.B., B.S. Lond., House Surgeon to Eye Department; LUCAS, H. A., M.R.C.S., L.R.C.P. Lond., House Surgeon to Nose, Throat, and Ear Department; ROBERTS, O. W., M.R.C.S., L.R.C.P. Lond., House Surgeon to Urological Department; WOOD, W. S., House Surgeon to Orthopedic Department; SURRAGE, H. J. R., M.R.C.S., L.R.C.P. Lond., Obstetric House Surgeon; CREED, E., M.B., B.Ch. Oxon., Bacteriologist.

Certifying Surgeons under the Factory and Workshop Acts: ATKINS, G. E., M.R.C.S., L.R.C.P. Lond. (Wombwell); FLOOD, C., L.R.C.S. Irel., L.A.H. (Gravesend); USSHER, N. R., L.R.C.P. & S. Irel. (Garstang).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne Union.—Asst. Med. Supt. and Asst. M.O. £300.
Bath, Royal United Hospital. Res. M.O. £150.
Birmingham General Hospital.—Res. M.O. £155.

Bloomsbury Dispensary, 12, Bloomsbury-street, W.C.—Res. M.O. £250.
Bradford City.—Female Asst. M.O. £450 plus £67 12s.
Bradford Royal Infirmary.—Res. Surg. O. £250. Hon. Dent. S.

Bristol, Cosham Memorial Hospital, Kingswood.—Res. M.O. £200.
Bristol General Hospital.—Cas. H.S. £175.
Bristol Royal Infirmary.—Throat H.S., and Cas. O.

Canterbury, Kent and Canterbury Hospital.—Hon. Dent. S.
Cardiff, King Edward VII. Hospital.—H.S. £200.
Chesterfield and North Derbyshire Royal Hospital.—Jun. H.S. £250.
City of London Hospital for Diseases of the Chest, Victoria Park, E.—Res. M.O. £250.

Colchester, Royal Eastern Counties Institution for Idiots, Imbeciles, and the Feeble-minded.—M.O. £400.
Colchester, Severalls Mental Hospital.—L.T. Asst. M.O. 7 guineas per week.

Derby, Derbyshire Royal Infirmary.—Asst. H.S. and Cas. O. £200.
Deadnought Hospital, Greenwich.—H.S. £100.
Durham County Hospital.—H.S. £200.

Edinburgh, Royal College of Physicians Research Laboratory.—Supt. £1000. Also Asst. to Supt. £500.
Elizabeth Garrett Anderson Hospital, Euston-road.—Female Clin. Assts. in the Venereal Diseases Dept. £1 ls. per session. Also Anaesthetist. £10 10s.

Galway, University College.—Prof. of Anat. £658.
Glamorgan County Council.—Female Med. Inspector. £600.
Gloucester County Asylum.—Jun. A.M.O. £300.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.
Hampstead General and North-West London Hospital, Haverstock Hill, N.W.—Cas. S.O. £150.

Hospital for Consumption and Diseases of the Chest, Brompton.—Asst. P.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S. £50.
Huddersfield County Borough Education Authority.—Dent. S. £450.

Kettering and District General Hospital.—Res. M.O. £300.

London Temperance Hospital, Hampstead-road, N.W.—Asst. Res. M.O. £120.
Maidstone, Kent County Council.—Tuberc. O. £670.
Maidstone, Kent County Mental Hospital.—Jun. Asst. M.O. £300.

Maidstone, West Kent General Hospital.—H.S. £250.
Manchester, Ancoats Hospital.—Res. M.O. £150. Two Jun. H.S.'s. £100. Hon. Dent. S.
Manchester Victoria Memorial Jewish Hospital.—Res. M.O. £150.

Middlesex Hospital, W.—Surgical Registrar.
Middlesex Hospital Medical School.—Chair of Radiology. £1000.
Norwich, Administrative County of Norfolk.—Tuberc. O. £600.

Plymouth, South Devon and East Cornwall Hospital.—H.P. £140.
Prince of Wales's General Hospital, Tottenham, N.—Jun. H.P. £120. Also Hon. Asst. S.
Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—District Res. M.O. £80.

Roll of Honour Hospital for Children, 688, Harrow-road, W.—Female Hon. Asst. P. and Temp. Asst. P.
Rotherham Hospital.—Jun. H.S. £150.
Royal College of Surgeons of England.—Examiner in Dent. S.

Royal Ear Hospital, Dean-street, Soho, W.—H.S.
Royal Institute of Public Health.—Sen. Demonstrator of Bacteriology.
Ryde, Royal Isle of Wight County Hospital.—Res. M.O. £250.

St. Albans, Herts County Mental Hospital, Hill End.—Locum Tenens M.O. Eight guineas a week.
St. Helens Education Committee.—Dentist. £500.

St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—H.S. £150.
Sheffield Hospital, Albert Dock, Connaught-road, E.—H.S. £100.

Sheffield Royal Hospital.—Asst. Cas. O. £150.
Sheffield Royal Infirmary.—H.P. £150.
Sheffield University.—Demonstrator in Anat. £350.

Sunderland Royal Infirmary.—Jun. H.S. £200.
Stafford, Staffordshire General Infirmary.—H.S. £250. H.P. £200.
Staffs Education Committee.—Practitioners under M.O.H. and Sch. M.O. £500.

Swansea General and Eye Hospital.—Jun. H.S. £200.
Townsville, Queensland, Australia.—Director, Institute of Tropical Medicine. £1200.
University College Hospital, Gower-street, W.C.—Hon. Asst. in Ear, Nose, and Throat Department.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—H.P. and H.S. £100.
Wakefield, West Riding Asylum.—Jun. Asst. M.O. £400.
Walsall General Hospital.—Hon. Asst. S.

Warrington Infirmary and Dispensary.—Jun. H.S. £200.
West London Hospital, Hammersmith, W.—H.S. and H.P. £50. Also Asst. S.
Westminster Hospital School of Medicine, Broad Sanctuary, S.W.—Obstetric Tutor.

Worcestershire County Council.—Asst. County M.O.'s and Sch. Oculist. £500 each.
Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Sheffield and at Sleaford.

Births, Marriages, and Deaths.

BIRTHS.

HARDY.—On June 29th, at Leigham-court-road, Streatham, the wife of G. Frank Hardy, M.C. (Captain, R.A.M.C.), of Highlands, Champion-hill, S.E., of a daughter.

ROY.—On June 28th, at Lower Belgrave-street, the wife of D. W. Roy, M.B., F.R.C.S., Upper Brook-street, of a son.

MARRIAGES.

CURRIE-HARVEY.—On June 30th, at All Souls, Langham-place, London, Walter Thompson Currie, M.B., Ch.B., to Annie Wallace, eldest daughter of the late Andrew Harvey, of Greenlaw, Woldingham, Surrey, and South India.

GIBSON-CHAPMAN.—On June 29th, at St. John's Church, Putney, Captain Colin Gibson, R.A.M.C., to Lorna Rougier, fourth daughter of G. H. Chapman, Woodboro' Lodge, Putney.

SINCLAIR-BERRIDGE.—On June 24th, at Holy Trinity Church, Brompton, Andrew Fulton Sinclair, F.R.C.S., to Janet Mary, daughter of Mr and Mrs. Charles Berridge, formerly of Ripley, Surrey.

VICK-NEVILLE.—On June 30th, at the Church of St. Martin-in-the-Fields, R. M. Vick, O.B.E., F.R.C.S., of the Warden's House, St. Bartholomew's Hospital, to Jane, eldest daughter of M. K. Neville, Esq., 25, Eccleston-square, S.W.

DEATHS.

BLAKE.—On July 3rd, suddenly, at Regent-road, Great Yarmouth, Henry Blake, M.B., B.S. Lond., aged 68 years.

HANDFIELD-JONES.—On July 2nd, Charles Montagu Handfield-Jones, M.D., F.R.C.P., aged 65 years.

SUTHERLAND.—On June 27th, at the Prince of Wales Hospital, Calcutta, of peritonitis after operation, Colonel W. Dunbar Sutherland, Imperial Serologist, M.D., C.I.E., I.M.S.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NEW HOSPITAL FOR THE TREATMENT OF SURGICAL TUBERCULOSIS.—The Exeter Town Council is joining with Somerset, Devon, and other authorities in erecting a joint hospital for the treatment of surgical tuberculosis. The cost to Exeter is estimated at about £2500 for 10 beds, with £1 5s. for maintenance of each bed.

DONATIONS AND BEQUESTS.—Among bequests left by the late Mr. Thomas Jeremiah Williams, of Morriston, Swansea, is one of £1000 to the Swansea General Hospital.—By will the late Mr. John Thomas Gipson Clarke, of Leicester, left £1000 to the Royal Infirmary, Leicester; £500 each to the Leicester and County Saturday Hospital Society and the Leicester Guild of the Crippled; £200 each to the Leicester Blind Institute, the Leicester Wycliffe Society for Helping the Blind, the Leicester Surgical Aid Society, and the Institution for Diseases of the Skin.—The late Mr. Edward King Mason, of George-road, Edgbaston, Birmingham, has left by will £500 to the Queen's Hospital, Birmingham; £200 to the Orthopaedic Hospital, Birmingham; £200 to Middlemore's Homes; £200 to the Birmingham and District Crippled Children's Union; £200 to the Society for the Prevention of Cruelty to Children, Birmingham.—The Chelsea Hospital for Women has received from an anonymous friend a donation of £200 for its convalescent home at St. Leonards-on-Sea.

Notes, Short Comments, and Answers to Correspondents.

AN INQUIRY INTO THE MENTALITY OF JUVENILE ADULT DELINQUENTS.¹

BY JOHN M. AHERN, M.B., B.Ch. N.U.I.,
MEDICAL OFFICER, H.M. BORSTAL INSTITUTION, BORSTAL.

THE results of an inquiry extending over rather more than 12 months into the mentality of the inmates of H.M. Borstal Institution, Borstal, should be of some interest in regard to the important question of the relationship between "juvenile adult" crime and mental defect. A sentence to a Borstal institution is given to young criminals who are passing through the plastic adolescent period of life—that is, from 16 to 21 years of age. In a few exceptional cases the maximum limit is extended to 23. The name of "juvenile adult" is given to this class of offender. The sentence is either for two or three years, but as a rule for the longer period, in accordance with the recommendation of the Prison Commissioners. The actual period of detention beyond a certain minimum is almost wholly dependent on the conduct of the inmate and the progress he has made in his training, but the longer sentence allows more time for the guidance and observation of his conduct on the conditional discharge, which he earns, and for his return to the institution should this prove unsatisfactory. The after-care is carried out by the Borstal Association, and their function may well be compared to that of a crutch after the removal of splints. To be deprived of its assistance too soon may mean a return of the old condition and the loss of an irreparable chance of its remedy.

The Two-fold Object of Treatment.

The object of the Borstal sentence is twofold—penal and reformatory. Each inmate has to pass through successive stages, in the first of which the penal element predominates, to be gradually replaced by reforming influences until in the final stages it practically ceases to exist and is succeeded by as large a measure of personal freedom and privileges as is compatible with a well-regulated institutional life. The freedom from close supervision, and the sense of trust by which it is replaced, together with the more intimate association with others, is a near approach to the conditions and temptations of the world outside. A most suitable atmosphere is formed for the observation of mentality, and the behaviour of an inmate under these conditions is of itself a mental test of the highest value and significance. One of the beneficent results of the Borstal system is that it affords an opportunity for mental grading which should be of great value in future years when dealing with cases that show an early history of crime. Most of them will have passed through a Borstal institution at the most likely age for tests and observations to show any existing defect, and thus the consideration of the mentality of the offender can take its place in the scales of justice to a much greater extent than is possible to-day.

The depth of the delinquency of the inmates—the extent to which their minds have been formed by criminal habits—has a bearing upon the subject. Almost all have had one or more previous convictions, and have failed to be weaned from their criminal ways by the supervision of the court probation officer. In a few cases a single offence only has been committed, but of an exceptionally serious nature, or under a bad home environment from which removal is an essential preliminary to reformation. Over 90 per cent. of the inmates have been guilty of repeated thefts or allied offences, and practically all have strong and obdurate criminal tendencies which, if fostered by short and repeated terms of imprisonment, would most assuredly lead to their ruin.

Factors Invalidating the Inquiry.

There is one qualification that a juvenile adult offender must have before his admission to a Borstal institution—he must be free from such mental or physical defect as would prevent him from responding to influence and training. On the physical side this does not mean that he must be free from all defect, provided that it is not of such a degree as to prevent his being taught a trade of a sedentary character, such as tailoring or boot-repairing. Similarly, a slight degree of mental dullness is not a bar to admission. The low-grade defective should never come to a Borstal institution, though unfortunately—owing, no doubt, to war conditions—some have crept in who should really have been certified under the Mental Deficiency Act. Thus the proportion of mental defectives found in the institution is not

a true estimate of the part played by the defectives in "juvenile adult" crime. How far it underestimates this proportion I have no data to determine. A second factor that might invalidate the results of the inquiry is that it does not include all those sentenced to detention in a Borstal institution within a given time. There was not, however, so far as I know, any special selection of those who were sent, so that they may be taken as a fair sample for statistical purposes. Finally, it must be borne in mind that there would naturally tend to be a concentration of mental defectives, as they would be slow in qualifying for discharge. As a matter of fact, I find that about one-third of those certified defective within the period under review were detained considerably beyond the average time for discharge.

Details of the Investigation.

The inquiry extends from Feb. 1st, 1919, to March 31st, 1920. On the first of these dates there were 434 inmates in the institution, and during the succeeding 14 months 494 additional inmates were received, making a total of 928. This number was too large, and the time at my disposal too limited to admit of systematic grading. Of those already in the institution the most obvious and insistent cases had to be dealt with first, whilst fresh arrivals were put through an examination less exhaustive but sufficient to detect mental defect or to question its existence. These were noted for subsequent detailed examination and inquiry. The work is tedious, fatiguing, and cannot be hurried.

The scheme of examination followed was drawn up rather with the intention of ascertaining the nature of the defect than of attempting to assess the mental age at which development had arrived. The mental tests were selected from various authorities on the subject, and call for no explanation or special recognition.

The investigation was carried out under the following heads:—

- A.—Range of information apart from that acquired by rote or school work.
- B.—School standard in reading, writing, and arithmetic, with progress being made.
- C.—Questions on incidents of past life with a view to testing recent and distant memory.
- D.—The following mental tests: 1. Enumeration of 12 objects observed for one minute. 2. Repetition of figures. 3. Repetition of sentences. 4. Taking key off split-ring. 5. Interchange of clock hands. 6. Cancellation of a letter in a printed passage. 7. Copy of two simple diagrams from memory. 8. Giving words of opposite meaning. 9. Successive deductions of 4 from 100 and 7 from 100.
- E.—Particulars of past offences.
- F.—School and home history.
- G.—Employments before admission with wages earned.
- H.—Progress in the institution with opinion of his instructors.
- I.—Conduct in the institution with any evidence of emotional weakness.
- J.—Employment of spare time and use made of library, with inmate's description of books read.
- K.—Family history in relation to insanity, "fits," crime, and drink.

There was no pedantic importance attached to the failure to comply with one or more tests. Each case was viewed from the broad standpoint of whether there was a fitness for the competition of life, even in its humblest capacity, or whether it were not kinder to put into operation the powers of a protecting State than send adrift to prey upon society, the helpless victim of his own imperfect organisation.

Results.

Working on this basis 37 inmates were certified under the Mental Deficiency Act. Eleven more were considered to be within the Act, although not actually certified either on account of their transfer to another establishment or their discharge before action was taken. Of 30 inmates who were removed on account of continued misconduct, probably 20 came within the terms of the Act, although the detailed examination and inquiry had not been made. There remain in the institution close on 20 who are, in my opinion, certifiable. To these figures should be added 4 who were certified insane, and may be presumed to have had a pre-existing mental defect. This makes a total of 92 defectives in a population of 928—or approximately 10 per cent. This figure I hold to be a very conservative estimate. It takes no account of the border-line cases and of the large number who show varying degrees of mental defect. The line which marks off those who are certifiable under the Mental Deficiency Act is of necessity vague and uncertain and largely dependent upon the views of the examiner. Individual opinion will, however, be kept in constant check by the knowledge that it will have to be endorsed by subsequent examiners.

The mental defect observed may be considered under three forms according to the predominating features of their blend: (1) defect of intellect; (2) defect of emotional functions (lack of control, mental conflicts, &c.); (3) moral imbecility.

Defect of Intellect.

Defect of intellect much below the average is not difficult to discover or demonstrate. The stage of development which they have reached can be more or less approximately

¹ Published by permission of H.M. Prison Commissioners.

gauged by the Binet-Simon method or some modification of it, and expressed in terms of mental age. This measurement was not undertaken, but I can say that no case was certified on the ground of defect of intellect alone who approximated to a development of 12 years. In the bulk of cases certified defect of intellect was so obvious a feature that I class them under this head, but there were few, if any, who did not show some signs of emotional defect as well.

There seems to be a widespread though erroneous view that the mental defect and defect of intellect are synonymous terms. This is not so. Mentality implies something more than intelligence, and so, too, does the defect thereof; in fact, I question whether criminal propensities exist as a result of mere defect of intelligence. How often is the village fool of an amenable and inoffensive disposition, and trusted to play a small though useful part in the life of its community. Unfortunately, there is no measurement for emotional defect as there is for that of intelligence.

Emotional Defect.

Emotional defect of pronounced form most often shows itself in misconduct; this does not, of course, imply that all misconduct is to be attributed to this cause. The misconduct of the mentally defective has as a rule certain well-marked characters which make it easy to distinguish. In the first place, it is purposeless. In this connexion I would again refer to the strong inducements which exist for good conduct in a Borstal institution. Not alone are there privileges to be earned, but there is, above all, a possible discharge after one quarter of the period for which the sentence was given has elapsed. The minimum period of detention has recently been extended, but its contrast to the full sentence must still be a potent influence to the mind of the average lad. Continued misconduct of a purposeless character that sets at naught individual interest is always suggestive of mental defect either on the side of intellect or emotional control. The offender is at least a dullard in the school of experience with an unnatural disregard for his own happiness or an inability to appreciate or be guided by the obvious consequences of his acts. Especially is it suggestive when the misconduct takes the form of destructiveness. An inmate who picks up and smokes a "fag," who steals an egg from the institution farm, or who absconds, takes a reasonable gamble for gain or gratification, although it is interesting to observe that those who have tried to abscond were mostly mentally defective, as experience showed the prospects of ultimate escape to be practically nil. The inmate guilty of this class of rational misconduct is from a mental point of view in an altogether different category from that of one who aimlessly smashes up the institution property or has at most some half-formed illogical idea of "getting his own back."

Emotional defect is not inconsistent with good intelligence, but in the young offender it is most often accompanied by a deficiency in this respect, though not always of a marked degree. It may be described as a riot of emotions in which volition has become usurped. When the fury has spent itself volition regains its weak dominion, but with no greater power of control or of preventing a recurrence of the disorder on the slightest irritation. It manifests itself in a fitful series of explosive acts, most frequently destructive or violent. A mood of repentance follows, with promises of amendment, and later on the paroxysms recur with renewed violence. Asked why they behave in this way, these lads will often say that they cannot help it, or that it gives them relief. Psychic epilepsy is an expressive term for such a condition. The nature or degree of misconduct bears no relation to its cause; it may originate in some trivial or fancied grievance, and not infrequently it is imitative.

Lastly, physical signs of the emotional disturbance may often be noted, such as quivering of the lips, twitching of the facial muscles, or other evidence of motor restlessness or incoördination. Headache and head sensations are frequently complained of. It may be urged that much of the emotional weakness described might be due to an adolescent instability that will pass off when maturity is reached. Their past and family history and the depth of the defect will probably in most cases serve to eliminate those who are only temporarily affected, but even in these cases it is most important not alone to the State but to the individual himself that he should be kept under a controlling supervision so long as the defect continues, as criminal habits formed in this phase are likely to remain when the phase passes off. For this reason a longer period of detention than can be secured by a sentence to a Borstal institution is advisable in some cases.

I have already pointed out that unless cases of emotional defect show also a considerable lack of intelligence their certification is often a matter of the greatest difficulty. Their good behaviour under rigid supervision is no proof that their misconduct is merely badness which they are well able to control. The question is not how the subject of emotional weakness is going to act under purely artificial conditions, but how he is going to act in ordinary life. A

soldier urged forward by a revolver to meet the enemy is not accounted a brave man, nor can it be said that his power of self-control is sufficient of itself to overcome his sense of fear or his impulse to run away, and the conditions are not incomparable. However well-behaved and hard-working under close supervision, the subjects of emotional defect are incapable of continued effort or undivided attention when left to themselves. They are excitable, easily distracted, and readily influenced; they are thoughtless, idle, and mischievous, and, in fact, one may say that on the emotional or affective side of the mind they have not developed beyond childhood. Mental tests show that though deficient in attention and judgment they are not much lacking in general intelligence. Their range of general information is good and their standard of education is up to the average of this class. These boys will neither be kept, nor want to remain, long in any employment, and, when out of work, will take the line of least resistance and drift into crime, possibly as the tools of stronger minds. It is exceedingly difficult to know what to do with them. Many will doubtless improve as they grow older, but in others, the defect which was the chief factor of the criminality already shown will continue to influence them for some years after their discharge. Unfitted for the competition of life, many of them will, I am afraid, become habitual criminals.

The Moral Imbecile.

The last class of case to which I would refer is the moral imbecile. Of the 37 inmates certified, 5 came under this heading. The whole question of moral imbecility is one beset with difficulties. Some authorities deny the existence of such a class as distinct from the other forms of defect, whilst its limits are various and uncertain. A high authority defines a moral imbecile as one who "has no conception of any social or moral obligation, and is lacking in the higher faculty of control and wisdom," but in my view such a definition does not cover the cases of moral imbecility met with among the criminal classes. Something more is required than a mere passive negation of the moral sense unless it connotes, however illogically, an antisocial perversion of it. Hostile to every regulation and social restraint, certain boys delight in misconduct for misconduct's sake. They treat kindness as a weakness and punishment only stimulates their bad behaviour. The so-called prison lawyer is often a type of this class. They satisfy one condition of the definition of moral imbecile contained in the Mental Deficiency Act—i.e., they show an incorrigible moral perversity; but unless there is other evidence of mental defect this is, from the point of view of responsibility, treated in law the same as any other perversity. In many of these cases evidence of some permanent defect that has existed from an early age may be obtained, and then they can be dealt with under the Mental Deficiency Act as "moral imbeciles." In these cases it is evidently the intention of the Act (and very rightly, in my opinion) that a lesser degree of defect should suffice for their certification than if no strong vicious or criminal propensities existed. With regard to the condition laid down, that punishment must have little or no deterrent effect, this would seem to be satisfied by a continuous history of misconduct from childhood, continuing under reforming influences such as those of a Borstal institution.

The marked correlations between mental and physical development is well exemplified by those who were certified to be mentally defective. Although the average height of the Borstal inmate is over a couple of inches below that of the general population of the same age, the average of the defectives was as much again short of this low standard on their removal from the institution, notwithstanding its excellent dietary and healthy surroundings.

The percentage of Borstal inmates who get re-convicted after their discharge is about 30. This percentage of failures is not too high to be largely accounted for by border-line cases and those who are too severely handicapped by physical defects. I believe that a study of the mentality of these cases will justify the opinion that, given a lad whose mental development is within reasonable limits of the average and whose criminal habits are in the main the result of environment, bad companions, or incompetent parental training, the Borstal system seldom fails to turn him into a law-abiding, wage-earning citizen.

PUBLIC HEALTH IN SIERRA LEONE, 1918.

THE population of the Colony at the last census was 75,572 (41,001 males and 34,571 females). The birth-rate in 1918 was 19 per 1000 and the death-rate 45 per 1000. In Freetown the birth-rate was 20 and the death-rate 62 per 1000. The number of European and American residents in the Colony in 1918 was 1036 (officials 185, non-officials 277, military 574).

The average number of resident European officials was 97. Among these, 158 cases were placed on the sick list for a total period of 1528 days. The average number of days upon the sick list for each patient was 9.67, and the daily average on the sick list 4.18. There were 6 deaths during the year, and 11 officials were invalided, the percentage of invalidings to the total number of residents being 4.84. Registration of births and deaths is compulsory in the Colony,

but not in the Protectorate. The excess of deaths over births registered in the Colony shows an increase this year of over 100 per cent. This excess, however, is due principally to an epidemic of influenza which visited the Colony in the latter part of 1918, and to which 1072 deaths were attributed. The annually recurring excess of deaths over births suggests that the population of the Colony is steadily decreasing, but as there is a constant influx of Protectorate natives into the Peninsula, and as the strict enforcement of the Registration Ordinance presents some difficulty the figures given must be accepted with caution.

The population of the Protectorate in 1911 was estimated at 1,327,560, of whom 3426 were non-natives. This estimate was based on the number of houses on which tax had been paid and on the assumption that so many persons live in one house, the number varying from 5 to 10 per house according to the custom of the tribe. During 1918 both the Colony and Protectorate were visited by a severe epidemic of influenza. It is estimated that two-thirds of the population contracted the disease and that during the month of September 3 per cent. of the native population died from this cause. The number of admissions to the hospital and the total attendance at the different dispensaries of people suffering from malaria showed a considerable decrease. Smallpox in a mild form occurred in various parts of the Colony and Protectorate, but partly owing to the new scheme of locally appointed vaccinators there was a large diminution in the total number of cases. Out of a total of 63,700 vaccinations reported as performed 32,033 were returned as successful.

Anti-malarial Measures.

Anti-mosquito measures on a much more extensive scale than hitherto have been carried out in Freetown. As there was reason to believe that malaria was being introduced into England by crews of ships infected at Sierra Leone, it was considered necessary to adopt more effective anti-malarial measures at the port, and a sum of £20,000 was accordingly set aside for this purpose. Mosquito-breeding plants and trees with natural or artificial cavities were systematically dealt with, and during the year 145 wells were closed. Only one case of yellow fever occurred during the year in Freetown, and, so far as is known, no cases occurred in the Protectorate. No case of plague occurred and no evidence of plague was discovered by the bacteriological examination of the 5987 rats caught during the year. The mean maximum temperature at Tower Hill Observatory was 94°00' F., while the mean minimum temperature was 62°00' F. The rainfall was 103·43 inches. To the European Nursing Home there were 288 admissions during 1918, 150 more than in 1917. The number of war vessels in the harbour and the influenza epidemic were responsible for the increased admissions. There were 25 deaths, which mostly took place a few hours after admission, from influenza and pneumonia.

The number of patients treated at the various hospitals and dispensaries throughout the Colony and Protectorate in 1918 totalled 55,562. At the Leper Asylum there were 3 patients at the beginning of the year. During the year 4 were admitted; 1 died, 1 absconded, and 2 were discharged, leaving 3 in the asylum at the end of the year.

THE FINAL CLOSURE OF THE BRIGHTON PAVILION HOSPITAL.

AN event received with great satisfaction by the inhabitants and visitors on June 25th was the reopening of the roadway through the Royal Pavilion grounds at Brighton. Since its occupation by the military authorities in the autumn of 1914, this roadway has been barred to the public. The fact that the Pavilion Hospital was evacuated of the last patients nearly eight weeks ago, and that the gates were still closed, was the basis of a recent question in the House of Commons, which elicited the news that the hospital would be entirely closed, and the premises handed over to the Corporation by July 14th. There has been yet another cause for agitation among the townspeople. In the latter period of the war, after the withdrawal of the wounded Indian troops, who were first located at the Pavilion Hospital, the hospital was devoted wholly to soldiers who had lost a limb, and this led to the establishment in the Pavilion grounds of some of Queen Mary's workshops. It is the future of these buildings that has provoked so much controversy. In spite of a strong feeling among the public in favour of the retention of the huts in the Pavilion grounds, the Brighton Corporation has decided that they must be removed. It is generally considered that the Pavilion site is an admirable one for the workshops, which at a trifling outlay could easily be made entirely independent of the Royal Pavilion estate. Moreover, the appeal from the Ministries of Labour and Pensions was that the workshops might be allowed to remain, not for all time, but for two years only. Those members of the Corporation who voted for their removal to a hilly neighbourhood amid a dense population seem to have quickly forgotten that these workshops were intended to benefit the men maimed in the war, from the horrors of which Brighton was to a large extent immune.

COTTAGE BATHS.

At Bradford, the *Local Government Chronicle* informs us, 2,898,905 baths had been taken in 1919 in "cottage baths," institutions originated by the local baths committee in 1906. The first cottage bath establishment was opened in what had been a stable, and 10 more have since been added. It is considered that a number of unpretentious bathing establishments placed near the homes of the persons for whom they are intended, encourage women to go who might not

care to go far and might be shy of entering more pretentious buildings with others of a different class from themselves. Overcrowding also is avoided to some extent. Most of the cottage baths at Bradford are set aside for children on four days of the week, and provision is made for taking children to them direct from school. They are supplied with soap and clean towels, the washing of those who are too young to look after themselves is supervised; verminous clothing is cleansed and dried. During the 12 months preceding March 31st, 1919, 73,258 slipper and shower baths were given to children free of charge. The idea appears to be a sound one and to have been carried out on practical lines. The bringing of cleanliness within easy reach of all who may desire it in the way indicated should be possible, whereas any general extension of bathrooms in houses for the working classes would almost inevitably tax the water-supply of most towns beyond reason. Waste of water would make up in some cases for neglect to use the baths in others, and a bathroom not used as such makes an expensive bedroom or lumber-room.

THE CHILDREN'S COUNTRY HOLIDAYS FUND.

WHILE the rise in prices has rendered the work of the Children's Country Holidays Fund more difficult, the cost of living, with its housing and food disabilities, has made the need for giving an annual holiday to the children of our slums all the more pressing. We therefore heartily endorse the appeal of the Earl of Arran, honorary treasurer of the Fund, for financial help in the sending of poor children to the seaside or the country for a fortnight's holiday. The cost for board last year was 9s. per week per child; it is now 12s. Subscriptions should be sent to Lord Arran at 18, Buckingham-street, London, W.C.2, or to the bankers, Messrs. Barclay and Co., Ltd., 1, Pall Mall East.

The State

AND THE

FUTURE OF MEDICAL PRACTICE.

An Address introductory to the Discussion on the Future of Medical Practice at the Eighty-eighth Annual Meeting of the British Medical Association.

BY SIR GEORGE NEWMAN, K.C.B., M.D. EDIN.,
F.R.C.P. LOND.

THE CLAIMS OF THE STATE ON THE DOCTOR.

MR. PRESIDENT AND GENTLEMEN,—From the earliest times the doctor has served the State, but in this country the direct official inter-relationship is not yet a century old. In 1830 the only direct medical interest of the State, as represented in the Government of the day, was quarantine and vaccination. But in 1831 the Government became anxious about the spread of cholera, then moving towards us from Russia, and an Advisory Board of Health was formed, cholera dispensaries established, and inquiries instituted. One of the results was a measure of defence against cholera, but, far more important, interest was awakened in the insanitary conditions amid which the mass of the people lived—an interest which was confirmed by the inquiries of the Poor-law Commissioners appointed under the Poor-law Amendment Act of 1834. No statute before that of 1834 had definitely provided for the State medical treatment of the pauper, though from 1536 the sick poor had been differentiated from the able-bodied. The famous Poor-law of Queen Elizabeth in 1601 had required the "necessary relief" of the disabled pauper, and under that enactment a wide and rather indiscriminate practice of medical treatment had in fact arisen. Thus it came about that between 1834 and 1838 the Poor-law medical service emerged as the forerunner of the public health service; in 1839 Farr began his work on medical statistics; in 1847 the first medical officer of health was appointed; and in 1855 a central medical department was established in Whitehall—first, under the Board of Health (1855–58), then under the Privy Council (1858–71), then under the Local Government Board (1871–1919), and, lastly, under the Ministry of Health (1919). These four historical steps in development from the Poor-law origin laid the foundation of the present position of State medicine for the civil community—the Poor-law medical service under 636 Poor-law unions and upwards of 4000 medical men, the public health service under 1800 sanitary authorities and 318 local education authorities, with a composite staff of another 3000 medical officers, the Registrar-General's Department, and the Ministry of Health.

Alongside this entrance of medical men into direct State service there was constantly proceeding a further imposition of statutory duties upon the medical practitioner. Apart from the fact that he may be called upon to undertake official duties in the public service he is liable *under statute* in the following respects:—

1. He must certify births and deaths (Births and Deaths Registration Act, 1874), and notify all births within 36 hours (Notification of Births Acts, 1907–15); he must notify cases of infectious disease (Infectious Diseases Notification Acts, 1889 and 1899, and special notification regulations as issued), of industrial poisoning (Factory and Workshop Act, 1901), and of verminous children (Children Act, 1908). He must also be ready to vaccinate (Vaccination Acts, 1871–1907) and to certify the removal of infectious cases to hospital (Public Health Act, 1875).

2. He may be called upon to inspect and certify for house disinfection (Public Health Act, 1875, and Infectious Disease Prevention Act, 1890), and be prepared to issue certificates for the removal and burial of dead bodies (*Ibid*).

3. He may be required to inspect and condemn in regard to nuisances and insanitary house property (Public Health Act, 1875, or Amendment Act, 1907), or inquire into unhealthy or insanitary areas (Housing of the Working Classes Act, 1890).

4. He must know something of the ill-effect upon health of dangerous or offensive trades (Public Health Act, 1875), and of unsound food (Public Health (Unsound Food) Regulations, 1908).

No. 5055

5. He must be competent to diagnose all forms of mental disease (Mental Deficiency Act, 1913).

6. He must be available to respond to the requirements of the local sanitary authority for the provision of medical assistance and treatment for the poorer inhabitants of the district in which he lives (Public Health Act, 1875, s. 133).

7. He is liable for a series of duties in regard to workmen's compensation (Workmen's Compensation Act, 1906, s. 8), superannuation, and pension claims (Ministry of Pensions Act).

8. He may be called in by a midwife to assist in cases of emergency (Midwives Act, 1918, s. 25).

9. The local education authority may avail themselves of his services in connexion with the treatment of children and young persons (Education Act, 1918, s. 25).

Lastly, the State has in recent years organised in behalf of the community certain branches of ordinary and special clinical work. The National Insurance Act of 1911 brought 12,000,000 insured persons into medical benefit, at present provided by 12,000 doctors and 10,000 chemists; systematic provision has been initiated for tuberculosis, venereal disease, and maternity and infant welfare; the organised treatment of early mental disease, ophthalmology and tropical disease, and the large questions of orthopaedics and the treatment of industrial diseases are now under discussion; and an ever-widening field of public dispensaries, clinics, and hospitals has opened before the profession.

CONSEQUENT NEW RELATION BETWEEN STATE AND DOCTOR.

These are profound changes. They divert, in a handful of years, the whole course of applied medicine from its century-old pathway. They do not abolish the private medical practitioner, but they bring him into a different relation to the State. Their present and future relation must be confirmed and made good on both sides, for, on the one hand, the profession is conscious of new obligations, both those imposed by law and those imposed by a sense of what is demanded by the civilisation in which they live; and, on the other, the State is conscious, as never before, of the community's need of the profession, and the value of the profession's help if sought on the right terms and given in the right spirit. The greatest need on both sides is understanding. Value is the result of the application of mind to matter. The new problem is for State and profession to come to a realisation of the principles which should govern their inter-relation. It is an association peculiarly difficult. For historical reasons the State (which means for the present purpose all authorities, local as well as central, concerned with health) has seen *prima facie* in the profession a body insistent upon the privacy and individuality of its work, the sanctity of its traditions, the freedom of its engagements. Correlatively the profession has seen in the State an organisation apparently devoted to the infringement of these traditions and incapable of putting anything worthy in their place. It has been suspicious and mistrustful of what it considers to be unnecessary intervention. It has feared the imposition of some cast-iron system, some form of so-called "nationalisation," the institution of a whole-time civil service, which might in practice make the practitioner of medicine servile, dependent, and fettered.

What can improve this relation? The answer to this question seems to be—a larger measure of understanding by the doctor of the business of central and local government as representing the whole community, and by the State and its officers and representatives, high and low, of the history, development, and genius of professional character. The doctor should know something of the respective functions of Parliament, of the Cabinet, of the Treasury, of the dozen departments dealing with health problems as subordinate to their main functions, of the Ministry of Health (medical and lay), and its Medical Consultative Council. Further, he should know the meaning of the English system of local government; how it has evolved; why the country is subdivided into shires, boroughs, urban and rural districts and parishes, and what the main purposes are of the respective bodies providing for health, pensions, Poor-law, education, and insurance. For it is only by

such knowledge, inspired by the historical spirit, that the doctor can obtain a grasp of the machinery by which and through which he can render his communal service to the State. He will discover, incidentally, the working of some of the great principles of representative government and the guarantees of its freedom.¹ The layman, what Anthony Trollope, following ancient custom, called "the clerk," besides specialised knowledge of the law and practice with which he is primarily concerned, should learn as much as he can of professional tradition and sentiment, of the scope and opportunity of voluntary work (from the great hospitals downwards) which touches the profession, of professional organisations, and of their history and relation to each other.

Such knowledge on both sides has a direct bearing on the effective working out of the extended relations between the profession and the State which it is now recognised are inevitable. It would enable doctors to understand those necessary and, at first sight, rather remarkable limitations of Government action, which at present he deems to be merely stupidity. For instance, in official work regard must be paid to uniformity, to a "national minimum," to what is practicable rather than what is desirable, to the restrictions of the law, and to public economy. The layman in his turn will learn why doctors are jealous of their *private* practice, of the system of hospital appointments, of the restrictions of whole-time work under public authorities, of the whole personal nature of their relations with their patients, and of professional honour, integrity, and etiquette. These matters are not mere expressions of idiosyncrasy, prejudice, or narrowness of mind. They have behind them a long history, sound reason, and something of a philosophy. Some of them may be vestigial remains of a dead past; others have come to us, living, virile, and purposive, across 2500 years from the days of Hippocrates.

The general effect of this suggested change of outlook would be that the doctor became more political in the true Greek sense, and not with any partisan or meretricious meaning, but rather in the sense in which man was described as a political being, conscious and considerate of the community in which he lives; and Whitehall and the local authorities would realise how far short they are of full understanding of the profession, with whom they must work, and of its growing cohesiveness, its quest of truth, and its undying spirit of "love of humanity associated with love of craft."

FIVE PROBLEMS AWAITING COÖPERATION OF STATE AND DOCTOR.

Partly by way of illustration of the application of these general principles, and partly by way of demonstration of their necessity, I propose to mention briefly five outstanding problems which now face the medical profession in its relation to the State. It will be understood that my purpose is to open a discussion and not close one, and that I am speaking wholly in an unofficial capacity.

1. The Unit of Health Government.

The present system of local health government in England is like an Egyptian palimpsest, composed in several layers of design lying one upon the other. At the bottom there are the Poor-law unions, next above them and three times more numerous are the local sanitary authorities, superimposed upon which come the local education authorities (318), then the Insurance Committees numbering 145, and at the top the latest addition, the Local War Pensions Committees. Thus the whole country is mapped out five times over, but the charting has been done by different hands, at different times, and for different purposes, and hence arises duplication, overlapping, and confusion. There is confusion in areas and authorities, but there is no less confusion in the family. There are five local authorities concerned with maternity and infancy; three with children of school age; six authorities deal with persons of unsound mind or mental deficiency; four authorities are concerned with "sick persons"; three with the

aged poor; and five with the able-bodied poor. It is all anomalous, extravagant, and redundant, with a result which is ineffective and wasteful. What we seem to need in the abstract is, first, a *single unit of health government* with necessary subcommittees for particular purposes. The principles which should guide us in devising such a local authority are: (a) the concentration, as far as practicable, in one authority in each area, of the responsibility for all administration of health services from local rates, with or without Exchequer grant in aid; (b) the absorption of the work of the Poor-law and insurance in a public health service and the use by that service for the whole community of Poor-law medical institutions; and (c) the unification in appropriate committees of the local authority of all public medical provision for the sick and infirm of all ages. Clearly, there would be advantage in thus having one authority for all health purposes—for a Poor-law medical service, sanitation, education, insurance, and pensions—and towards unification of this nature many are looking. But the question is large and complex, and there are many considerations to which regard must be paid in prescribing a unit of sanitary government, including its history, size, population, urbanisation, character of industry and society, inter-communication, rating, relation to local and central government, and so forth. If a large local unit be contemplated, it would be necessary to provide for the encouragement of a consciousness of community of interest and aim in the smaller contributory or constituent divisions, with appropriate delegation of powers or functions in accordance with services to be rendered. The large autonomous body might in that way delegate some of the actual detail work to the more local bodies. If, on the other hand, a small local unit be contemplated, many analogous questions would arise. All I desire to do here is to name the general principle of unification as one to which attention must be given. There is a second, somewhat similar, common-sense requirement—namely, *uniformity of administration*—in all comparable areas. All through the country and in all departments of State medicine there is need for introduction of accepted standards and a larger measure of equalisation and uniformity of central and local action. There remains a third principle which the profession must not allow itself to forget—namely, that the local unit of health government must be *representative* of the will of the people as a whole. It cannot be wholly medical in personnel or in purpose. It must be comprehensive and disinterested. "Our trade our politics" is never sound statecraft.

Now, in devising this reform the medical profession must, in the interest of the State not less than the profession, take their share, exchanging with the layman their views on many points—the nature of the authority, its membership, the question of the coöption of experts, finance, medical participation, the respective functioning of the different local committees, the use and adaptation of existing institutions and their economical arrangement, and the place and character of the domiciliary medical services.

2. The Extension and Coördination of Medical Provision.

Here again is a pressing problem calling partly for unification and simplification and partly for systematic organisation. At present there are inadequacy, unequal provision, and piecemeal effort. We shall never get an ordered scheme in that way. We need a national policy—a programme, so to speak—dealing seriatim with the medical problems of maternity, infancy, children, adolescence, adult life, and old age; with environment of home and workshop; with the prevention and cure of non-infectious diseases as well as infectious; and with the education of the public in hygiene. Here to deal with infancy, and there to neglect it; here to have a "stunt" in venereal disease, and there to provide nothing; here to organise a public medical service, and there to leave all things to chance—is not the way either of science or common-sense. Then we require, in much greater degree, to bring together in proper relation the provision of medical treatment in the home, at the clinic, in the hospital,

¹ I may perhaps venture to commend a perusal of Lawrence Lowell's *Government of England* (2 vols.) or the little volume on *The English Constitution* by Walter Bagehot (in Nelson's Series), and the three admirable pamphlets on *The Business of Government* Ministry of Reconstruction, H.M.S.O., No. 38, 2d.).

and in the convalescent institution, not for the pauper class only, but for the whole of society. All this means that the profession should help in the consideration of these matters, for, while they constitute only a section of the community of ratepayers, and therefore have only a share in the decision, their knowledge and experience, and the fact that they must in large degree undertake the actual working of any scheme, entitles them to a voice in the form of the scheme. For what sections of the population should provision be made? For what forms of treatment? Under what principles as to availability, adequacy, and payment? What is to be the part or lot of the private practitioner in the undertaking? And, lastly, what does the medical profession say to the concurrent operation of three incomplete and independent public medical services (Poor-law, insurance, and public health), and is it possible to unify their divergent claims? and, if so, what should be the basis of payment and its relative burden on the State, on the local authority, and on the income of the patient.

3. *The Future of the Hospital System.*

A third example of problems awaiting us is that of the hospital position. The number of hospitals in England and Wales in 1915 was reported to be as follows:—

	No.	Beds.
General hospitals	594	31,329
Special hospitals	222	13,654
Fever hospitals	755	31,149
Small-pox hospitals	363	7,972
Poor-law infirmaries	700	94,000

This gives us approximately 2600 hospitals with 178,000 beds, of which 700 institutions and 94,000 beds belong to the Poor-law. In regard to this Poor-law accommodation three things must be said here: first, it is provided out of the poor rate and for persons in receipt of poor relief; secondly, of the 636 Poor-law unions only 54 possess separate infirmaries (of which 26 are in metropolitan unions), 331 unions have "sick" beds in the curtilage of the workhouse, and the remaining 251 unions have no special in-patient accommodation; and thirdly, a large proportion, perhaps even one-third, of the in-patient accommodation in all the Poor-law institutions is empty. These points are important when considering the practicability of transfer of Poor-law beds to the general community. No doubt from the medical point of view the community stands in urgent need of more hospital accommodation—we have overcrowded hospitals and long waiting lists on the one hand, and on the other inability to build new hospitals and yet many empty Poor-law beds. But the solution is not as simple as it looks, and the situation is complicated by many other hospital problems too often overlooked. Let me name some of them. Is the principle of voluntary financial support to continue in our hospital system, or is the profession in favour of Government aid and some measure of Government control? Ought the hospital accommodation of the community to be allocated by the State in respect of area or type of clinical work undertaken, or ought it to continue to be provided in haphazard fashion? Is the medical and surgical staff to remain honorary? Is it to be a special professional class, or composed in part, at least, of general practitioners? What is to be the relation of hospitals to each other and to contributory clinics, and to the insurance system? How are we to bring about the substantial reform of the out-patient departments which is so greatly needed? Ought we to make provision for paying patients, and, if so, on what basis? Can we fairly provide for the insured and the pauper whilst neglecting to provide for the remaining majority? And, lastly, what can be done to reorganise after-care and the proper convalescent treatment of the patient? These are some typical issues which arise, and they are but illustrations, for their right answers they require medical as well as lay judgment and experience.

4. *Medical Education.*

A fourth subject, and perhaps the most important of all, is an adequate method of medical education which

shall equip the undergraduate and the practitioner. The new services of the doctor to the State call for a reconsideration of the whole business of education and equipment. A different kind of doctor is needed in these new times. It is clear he must have no less of the learning and skill of former days, whilst he must also be furnished with an improved training in new subjects, in preventive medicine and in the political science of communal responsibility. We are all convinced that the pivot of the profession is the general practitioner. If he is properly equipped the future is safe. Some specialisation of practice there must be, for no man, be his powers what they may, can be master of all branches of medicine. Nevertheless, it is incumbent upon us to recognise that such diseases as tuberculosis and venereal and heart disease will never come under control until and unless the general practitioner is in a position to deal with them. Much of the special provision which has been made by the State in recent years has been necessary, first, because of the need for institutional accommodation to effect cure, and, secondly, because adequate treatment by the private practitioner was unavailable. In my view the State should never take out of the hands of the general practitioner, whether in contractual practice or otherwise, the patient whom he is willing and competent to handle on reasonable terms. The difficulty has been that the practitioner has not been in a position to render the medical service required by the State. It is evident that the solution is dependent partly upon reform in the medical schools—a reform which, happily, is proceeding rapidly—and partly upon adequate arrangements for graduate education for the practitioner, and may I add, willingness on his part to avail himself of the facilities which are provided. There is much remaining to be done in both directions, but before substantial progress can be achieved there is first considerable apathy to be overcome and a fuller apprehension of the needs of the situation; and secondly, the further education of the practitioner must include an adequate professoriate, hospital and laboratory accommodation, and proper organisation.

5. *The Advancement of Humanism.*

As this section is concerned with "Medical Sociology," I venture to suggest one other sphere in which the medical man of this new age may put in his oar. It is not only an intellectual or medical advance of which our country stands in need. Closely akin to it there is a social need. Men are great in proportion as they absorb the best life of the world in which they live—its ideas, knowledge, hope, fears, aspiration—and quicken these anew in the minds of other men. As Sophocles said—

"Much is there passing strange,
Nothing surpassing mankind."

No medical man who is in a right sense a man of the world can have failed to ponder often on the near relationship which obtains between the practice of medicine and the social life of the people. It has often been said our patients are not "cases," but men, women, and children, each with a separate personality, environment, heredity, and variation, with individual habits, training, temperament, and psychology. We cannot be wise healers of the patient or the community without a large sympathy and a liberal humanism—that fuller humanity with which the Oxford reformers inspired the Renaissance.

We are the witnesses of a strange and rapid transition in the life of the people as a whole, an enlarging franchise and new social complexes. Higher wages, shorter hours of work, increased leisure, high prices, and democratic aspirations are not remote from the national health and well-being. The doctor must be the missionary of hygiene—the chief educator of the people in the way of health. In being that, he cannot escape his share of responsibility in the study and handling of many of the medico-sociological questions which surround us—education, recreation, housing, the conditions of industry, sobriety, cleanness of living, the prevalence of venereal disease, prostitution, the

penal laws, the causes of certain crimes, the integrity of family life—all such questions concern us, and to fulfil our vows we must be concerned with them. The cultivation of international science, coöperation, and amity should also, I think, be added. It is essential that we should remember that whilst these issues belong to the warp and woof of medical polity the decisive factor is not medical, and movements in favour of their determination on medical grounds only are doomed to failure. Let me remind you of a famous passage in Huxley's lecture at Oxford in 1893 on "Evolution and Ethics." He had been speaking of the cosmic process of Nature, and he said (p. 33):—

Social progress means a checking of the cosmic process at every step and the substitution for it of another, which may be called the ethical process, the end of which is not the survival of those who may happen to be the fittest in respect of the whole of the conditions which exist, but of those who are ethically the best. The practice of that which is ethically best involves a course of conduct which in all respects is opposed to that which leads to success in the cosmic struggle for existence. In place of ruthless self-assertion it demands self-restraint; in place of thrusting aside or treading down all competitors it requires that the individual shall not merely respect but shall help his fellows; its influence is directed not so much to the survival of the fittest as to the fitting of as many as possible to survive. It repudiates the gladiatorial theory of existence. It demands that each man who enters into the enjoyment of the advantages of a polity shall be mindful of his debt to those who have laboriously constructed it; and shall take heed that no act of his weakens the fabric in which he has been permitted to live.

These words are even more timely to-day than they were when they were spoken. He added—

Most men are agreed that the proportion of good and evil in life may be very sensibly affected by human action. So far as we possess a power of bettering things it is our paramount duty to use it and to train all our intellect and energy to this supreme service of our kind.

The claims of the State on the profession have greatly increased owing to the advance of medicine and its manifold applications. A new and closer relationship between them is inevitable. It can be profitable to the public interest only by good understanding. There is something due from each to the other. The profession is responsible for its own contribution—a contribution which consists partly in a correct diagnosis of its own disabilities and the conflicting and prejudicial tendencies within its own body, partly in a fuller understanding of the needs of the State and partly in readiness to make itself thoroughly well equipped and competent to render the remarkable public service which in this generation has fallen to its lot.

THE MYOCLONIC FORM OF ACUTE EPIDEMIC ENCEPHALITIS.

BY ARTHUR W. M. ELLIS, B.A., M.B., M.R.C.P. LOND.,
ASSISTANT DIRECTOR, MEDICAL UNIT, LONDON HOSPITAL, E.

AT a meeting of the Société des Hôpitaux de Paris on Jan. 23rd Sicard and Kudelsky¹ described four cases of a new affection to which they gave the designation "encephalite aigue myoclonique." The disease as described by them was characterised by the onset of lancinating neuralgic pains with fever, followed by the appearance of short, rapid, explosive, rhythmical, muscular contractions resembling those produced by electrical stimulation. There were no ocular disturbances and no somnolence; on the contrary, insomnia was the rule. Finally, the speech became short and staccato, the gestures automatic, delirium almost constant, the muscular contractions diminished, the patient became comatose and died.

Sicard called attention to the exact resemblance of these cases to the series of cases described by Dubini in 1846, and to which the latter gave the name of electric chorea. Sicard discussed the probable common aetiology of this condition and lethargic encephalitis. Netter in the discussion insisted on the identity of this myoclonic condition with encephalitis lethargica, and stated that he had seen patients presenting the picture described by Sicard pass into the condition of typical lethargic encephalitis.

Following this discussion, reports of similar cases were given by Carnot and Gardin,² Ettinger,³ and Netter.⁴ In February, 1920, Briant and Rouquier⁵ described seven cases in which delirium and hallucinations were the most prominent symptoms. The patients were restrained with difficulty, were often violent, their features contorted, the face and limbs agitated, with brisk choreiform muscular contractions. Some scratched themselves and tore at the bedclothes. Their speech was scanning. Occasionally they had trismus, slight ptosis, intermittent strabismus, inequality of pupils, retention of urine.

Further instances of such myoclonic and delirious cases, and of cases showing both conditions, in some cases passing into the typical lethargic condition, have been described by Benard and Boissart,⁶ Roger and Aymes,⁷ Claud,⁸ Remond and Minvielle,⁹ Eschbach and Belétre,¹⁰ Brouardel, Levaditi, and Forestier,¹¹ Lereboullet and Foucart,¹² Laporte and Rouzard,¹³ Comby,¹⁴ Bourdillon and Olmer.¹⁵ In Switzerland several observers have also reported similar cases. In America Bassoe¹⁶ has noted delirious forms of lethargic encephalitis, and he and Reilly¹⁷ have both observed twitching of the abdominal muscles. At the meeting of the New York Neurological Society of March 2nd, 1920, Ramsay Hunt¹⁸ reported 12 cases of what he called "acute myoclonus multiplex." Two of these he had seen more than ten years ago and the remaining ten within three months. In the discussion which followed Rosenheck, Leszynsky, Neustaedter, and Leiner reported similar cases. The description of the cases was identical with that given by the French authors.

In Germany Cohn and Lauber¹⁹ have reported eight cases occurring in Stuttgart and similar cases have also been reported by Heiss.²⁰

In England no cases of this myoclonic type of encephalitis have, to my knowledge, so far been described, though Buzzard and Greenfield²¹ have described similar muscular contractions as a late sequela of lethargic encephalitis.

In the past few weeks three typical examples of acute myoclonic encephalitis, as described by the French authors, have come under my care in the London Hospital. All three presented the combination of insomnia, followed by acute delirium and rhythmical spasmodic contractions of muscles. In all the abdominal muscles were most affected.

CASE 1.—W. S. P., age 17, labourer; admitted London Hospital May 24th. Eight days before admission patient vomited and had severe pains in the lower abdomen and thigh. These increased in severity, and about four days before admission he began to have twitching of the muscles of the thighs and abdomen. He walked to see the doctor (50 yards) on May 20th and again on May 21st. The night of May 22nd and 23rd patient was delirious. He had not slept for a week before admission, and the bowels moved only once in five days, and then only with the aid of an enema. The insomnia was very distressing. For two days before admission there was difficulty in voiding urine.

On admission, temp. 101° F., pulse 100, respirations 36. Patient is in a very restless excited state; eyes bright and staring. Quite conscious, and answers all questions sensibly, but frequently lapses into a low muttering delirium. Face pale, tongue dry, brown, furred, much sordes on gums and lips. Pupils widely dilated, equal, react to light and accommodation. Slight left internal strabismus (said to date from childhood). No facial paralysis, no ptosis. Twitching movements of both extremities and of fingers of both hands.

There are rapid rhythmical shock-like contractions of the abdominal muscles, chiefly the recti abdominales. These occur occasionally bilaterally, but usually confined to one side. The muscle is very forcibly contracted and the umbilicus displaced. These contractions occur at a rate of about 30 to the minute, but the rate and rhythm are irregular. The movements consist of two main varieties, one in the upper segment of the abdomen and the other in the lower. The former consists of sudden contractions of the recti, usually unilateral. The contractions are usually confined to the upper half of the muscle, so that the umbilicus is pulled towards the epigastric angle. Less frequently a similar contraction occurs in the lower half of the muscle. The second main type of movement consists of similar contractions in the oblique muscles, giving a lateral pull in the lower segment of the abdomen.

May 25th: Lumbar puncture: clear fluid; cell count, 17 per c.mm.; protein, very slight increase. The urine contains trace of albumin, but is otherwise negative.

27th: Condition much the same but is more restless and excited. Did not sleep at all last night in spite of morphia and hyoscine. Frequently tries to get out of bed. Bladder distended, requires catheterisation. Bowels have not moved since admission. Pupils widely dilated; sweating profusely. Movement of abdominal muscles continues. Tendon reflexes in arms and legs all normally active. Coarse fibrillary twitchings of the muscles of the extremities. Speech explosive and indistinct.

28th: Seems slightly better, but still has not slept; occasional delirium. Muscular contractions unabated. Requires constant

catheterisation. Temperature 99.2°, pulse 120, respirations 38. W.B.C., 15,000; polys., 75 per cent.; eos., 1.5 per cent.; small lymphocytes, 11.5 per cent.; large lymphocytes, 2 per cent.; large hyaline, 10 per cent.

25th: Distinctly better, quiet, no delirium; still hardly sleeps at all, but occasionally dozes for a few minutes. Myoclonic movements still continue. Patient is wasting rapidly. Temperature 98°, pulse 120, respirations 28.

31st: Slowly improving; now quiet mentally, but still only dozes occasionally; myoclonic movements continue, but are becoming less forcible. Requires constant catheterisation.

June 1st: Steadily improving; slept for a few hours last night. Myoclonic movements in recti continue 30 to 40 to the minute, affecting both upper and lower segments, more often the former. Mental condition clear; no weakness of eye muscles; no facial asymmetry; no disturbance of sensation; no disturbance of sense of position. Tendon reflexes: arms, present; knee and ankle jerks absent on both sides; plantar reflex gives downward movement of the great toe.

3rd: Yesterday not so well. For the past two days there has been evening fever, temperature of 99.6° to 99.8°. Some delirium during the day yesterday, but when spoken to was quite bright and intelligent. Delirium during the night; only became quiet after two injections of morphia. To-day quiet and perfectly rational. Pulse rapid, 140. Pulse has not been below 120 for the past three days. Pulse regular and good volume; heart action shows no disturbance beyond that of rate; area of cardiac dullness not enlarged; heart sounds clear. Pupils no longer dilated. Myoclonic movements of recti muscles continue, intensity about as on June 1st. There are myoclonic contractions of moderate intensity of the hamstring muscles of both thighs. Sudaminal rash over face, chest, and abdomen.

4th: Condition much the same. Quite quiet. Myoclonic contractions of abdominal muscles continue. Speech is sputtering and difficult to understand. Slight fever; temperature 99 to 100° every evening. Pulse continues rapid, 120 to 140. Urine negative.

7th: On the morning of the 5th patient again became restless, excitable, and delirious, and this has steadily increased. This morning he is in a state of wild delirium. He is constantly on the move, grimacing with his face, and throwing his arms and head about. Quite often he will clasp his face with both hands, and frequently with both hands tears at the back of his neck. There is an incessant muttering delirium of which only occasional words can be made out. Sometimes he appears to think that he is boxing. Occasionally he recognises the people about him. He can be roused to understanding and can be made to take food, but to-day has apparently some difficulty in swallowing. Urine only by catheter; incontinence of feces this morning. The temperature has not been above normal since the evening of the 3rd; pulse constantly 125 and over. The myoclonic movements of the abdomen have ceased; those of the thighs are still present. Morphia has no effect in quieting patient, but hyoscine is more effective.

Lumbar puncture: clear fluid; cell count, 14 per c.mm.; protein, slight excess.

10th: Mental excitement and delirium continue. Never quiet except when under hyoscine, which seems to be the only drug that is of any value. Even under hyoscine there is almost constant activity. Patient evidently has constant visual hallucinations to which he responds. The arms are constantly on the move in what are evidently purposeful movements. These consist chiefly of what is apparently boxing and gymnastic exercises. (Before his illness patient spent much of his time at a boys' club, and in his delirium he constantly imagines himself there.) He has occasional attacks of violent temper, in which he strikes out at the nurse or whoever is about him. At these times his face assumes an expression of great cunning and malignancy. He can be roused to consciousness, and when roused understands what is said and does what he is told. He is taking his food a little better. The wasting has now become very marked, and the skin over the arms, shoulders, and thighs is raw from the rubbing of the bedclothes during the incessant movements. There are spasmodic contractions of the biceps muscles. The pupils are constantly widely dilated. Since June 6th there has been a marked change in the clinical picture. Before that time the muscular movements dominated the picture. Since that time the muscle spasms have been absent or insignificant, the predominant feature being the restlessness and incessant movement. The patient throws himself about and is for ever on the move.

14th: Since the 12th patient has been lethargic. He lies absolutely quiet with the eyes half open; is roused with difficulty, and can be made to take food only with great difficulty. Face and eyes sunken; emaciation marked; pulse good. For past two days patient has had some cough and sputum, and he is running low evening fever. Very constipated, constant catheterisation necessary.

15th: Died at 3 A.M. to-day. A few hours before death temperature rose to 104.8°.

CASE 2.—F. W., age 6 years, schoolboy; admitted London Hospital May 25th. Five days before admission patient vomited. The next day he complained of sudden pain in the back and lower abdomen and in the thighs; the pain was so severe as to make him cry out. Two days before admission his mother thought he seemed drowsy, and one day before admission he began to have twitching of the muscles of the left arm.

On admission, temperature 99°, pulse 100, respirations 24. Somewhat drowsy, but perfectly intelligent, and answers all questions readily. Pupils dilated, react to light and accommodation. There is no strabismus, ptosis, or nystagmus, and no facial asymmetry. There are forceful rhythmical, shock-like contractions of the lateral muscles of both sides of the abdomen, more marked on the right side. The recti abdominales are not affected. There are similar but more rapid and less forceful contractions of the muscles of the left shoulder girdle and left arm, especially the biceps, deltoid, and pectorals. The bladder is not distended. Tendon reflexes: arms and legs, present; no disturbance of sensation. Heart and lungs negative.

Lumbar puncture: clear fluid, cell count 7 per c.mm. Urine: trace of albumin.

May 27th: Not so well, has not slept at all, and has been restless, excited, and delirious, trying to get out of bed. Eyes bright and

staring, pupils widely dilated; no strabismus, ptosis, or nystagmus. Both arms show continuous muscular rigidity, and in both arms rapid rhythmical contractions of slight degree constantly recur at a rate of 70 to 90 to the minute, resulting in fine continuous twitching movements of the arms and hands. The most striking feature, however, is the shock-like rhythmical contractions of the abdominal muscles. These are so forceful as to shake the bed, and can easily be seen from across the ward. They occur at the rate of about 30 to the minute. They consist of shock-like contractions of short duration of the abdominal wall, chiefly of the lateral abdominal muscles. On each contraction the affected side of the abdomen flattens and dips in, pulling in the lower ribs and giving a jerking upward elevation of the pelvis on the affected side. There is no evidence of involvement of the diaphragm, no disturbance of phonation, and respiration continues quite unaffected by these involuntary movements. On palpation the muscles can be felt to undergo strong contraction. There is a striking preponderance of left-sided movements; on admission there was right-sided preponderance. At rest the movements recur at a relatively regular rhythm. At short intervals right-sided movements are irregularly interpolated. Tonic contraction of the abdomen, as evidenced in crying or holding the breath, exercises a very definite inhibitory effect on the contractions.

28th: Patient is highly excited, talking constantly, calling to his friends and brothers. His facial expression is extraordinary, he grimaces constantly, and frequently assumes an expression of low cunning and great malignancy, plucking at the bedclothes, picking his nose, and tries frequently to get out of bed. There are obvious hallucinations of sight and hearing. There is slight internal strabismus. Patient sweating very profusely, beads of sweat over his face. Requires constant catheterisation.

29th: Condition much the same. Very excited, has had to be put in seclusion. Did not sleep at all during the night, restless and excited. Myoclonic contractions continue. At 8 o'clock A.M. temperature 102°, pulse 132. There is a faintly vesicular, milky, sudaminal rash over the forehead, and especially marked over lower eyelids, upper lip, and chin. This rash is identical with that seen in Case 1. Tendon reflexes in arms and legs not elicited. W.B.C., 21,800; polys., 77 per cent.; eos., 0 per cent.; small lympho., 10.5 per cent.; large lympho., 4.5 per cent.; large hyaline, 5 per cent.

30th: Still excited and delirious, but slept a few hours last night. Muscular movements still present. Answers questions rationally and takes food well.

31st: During yesterday patient gradually grew weaker, finally became comatose, and died early this morning.

CASE 3.—M. N., Jewess, age 28, married, six months' pregnant. Admitted London Hospital, May 26th. One month before admission patient vomited and felt giddy. Then she had a sensation of pins and needles all over her body; this persisted. There was obstinate constipation. For 14 days previous to admission patient has had complete insomnia and is said "never to have slept." Some days before admission she began to have twitching of the muscles and difficulty in urinating. There was some blurring of vision but no diplopia.

On admission, temperature 101.4°, pulse 100, respirations 28. Patient rational but very talkative and excitable. There are constant rhythmical shock-like movements of the abdomen and occasional twitching movements of the thighs. The pupils are dilated, equal, and react to light and accommodation. There is paresis of the external rectus of the right eye and of the right side of the face, and ptosis of the left lid. Well-marked lateral and vertical nystagmus. Tendon reflexes of arms and legs not elicited, plantar stimulation gives downward movement of the great toe. Abdominal reflexes absent. No disturbance of sensation. Urine negative.

Lumbar puncture: clear fluid; cell count, 6 per c.mm.; protein very slightly increased.

May 28th: Temperature 101.4°, pulse 120, respirations 24. During yesterday morning patient became highly excited, constantly talking, pulling at the bedclothes, and trying to get out of bed. Hyoscine gave no relief and was repeated; following second dose she became quiet and stuporous. Cyanosis marked. Pulse small, rapid, and palpable with difficulty. Following lumbar puncture she again roused, seemed stronger, and grew very excitable. Excitement and delirium persisted all night. This morning she is quieter and seems better. Requires constant catheterisation. Speech is jerky and slurred.

There are forceful, shock-like movements of the abdominal wall recurring in fairly regular rhythm at a rate of about 30 to 40 to the minute. These are predominantly left-sided; in one observation 18 left to 5 right. The movements are exactly as described in Case 2—i.e., a rhythmical sudden flattening of the affected side of the abdomen, with a pulling down of the lower ribs and a lifting upwards of the pelvis on the affected side. The muscles chiefly affected appear to be the lateral muscles of the abdominal wall and the recti abdominales.

29th: Condition unchanged, very restless and delirious, but still has lucid intervals, in which she answers questions quite intelligently. No sleep, in spite of heavy doses of soporifics. Muscular movements unchanged.

W.B.C., 16,800; polys., 77.5 per cent.; eos., 0 per cent.; small lympho., 9 per cent.; large lympho., 7.5 per cent.; large hyaline, 5.5 per cent.; coarsely granular basophilic cells, 0.5 per cent.

31st: Temperature 100°, pulse 100, respirations 28. Yesterday patient was quieter but still sleepless. This morning quieter, semicomatose, with muttering delirium. Pulse weaker. Muscular shocks as frequent, but less forceful than formerly. Maximum temperature since admission 103°, on the evening of the 29th, minimum morning temperature 100°.

June 1st: Patient has been quiet since yesterday morning, and is now definitely lethargic. She can, however, still be roused, and when roused answers questions intelligently. She at once relapses, however, into unconsciousness with low muttering delirium. The myoclonic movements of the abdomen continue, but much less forcibly than before. Constant catheterisation has been required since May 28th. The eyes are now kept constantly closed and the pupils contracted. There is slight conjunctivitis of the left eye for the first time to-day.

3rd: There was no marked change in patient's general condition yesterday, but she gradually grew worse and died early this morning.

Remarks.

It will be seen that these three patients, admitted to the London Hospital within a period of three days, presented a clinical picture of striking similarity, and one which conforms accurately with the descriptions of acute myoclonic encephalitis in the foreign literature. In all three cases the initial symptom was vomiting, followed in two of the three patients by severe pain in the lower abdomen and thighs. There was obstinate constipation and difficulty in urination, followed in every case by complete retention. Insomnia was severe and led up to a wild delirium of the delirium tremens type; in one patient the insomnia was preceded by drowsiness. In all cases the most striking feature was the forceful, shock-like contractions of the abdominal muscles, which occurred at the rate of 30 to 40 to the minute. The pupils were widely dilated, there was profuse sweating and tachycardia. Fever, usually of low degree, was present in all. In two of the three speech was affected, jerky, indistinct, and slurred. Paresis of the eye muscles was present in one case and doubtful in another. One patient showed nystagmus. All three patients showed a well-marked leucocytosis, with a slight relative increase of the polynuclears. The urine showed a trace of albumin in two cases. The spinal fluid showed a very slight increase of cells and protein in all three cases, in two of these barely above the possible normal variation. In all three patients the disease was fatal.

Autopsies were obtained on two of the three patients. There were no gross lesions to be seen, except a moderate degree of cerebral congestion. Histological examination has not yet been completed, but will be reported in due course.

Two points observed in these patients do not seem to have been hitherto described—the leucocytosis and the dilatation of the pupils. It is interesting that with the onset of coma the dilatation of the pupils disappeared.

That these myoclonic cases are really epidemic encephalitis caused by the same ætiological agent as the lethargic form remains, of course, yet to be proved. But epidemiological and clinical evidence certainly strongly suggests their identity, and the scanty histological observations as yet available support this opinion.²⁴ It is worthy of note that all three of these patients became comatose before death, the condition in Case 3 being indistinguishable from that of an ordinary case of lethargic encephalitis. On the other hand, the occurrence of a leucocytosis in these cases is of interest, as in the lethargic forms Vaidya and Boyd²² and Edwin Bramwell²³ have found no such increase of leucocytes. This point of difference would therefore seem worthy of further investigation, especially as in our cases no complicating factors which would explain the leucocytosis were present.

If the ætiological agent is the same, the occurrence of this new form of case, which in the opinion of the French authors amounts to a fundamental change in the type of the disease, is presumably associated with a tendency of the virus to new localisation in the central nervous system. Such a change is of profound interest, both in the general problem of specific localisation of infections, and in the narrower problem of the change of characteristic localisation of a given infection during its epidemic evolution. The fundamental principles underlying these problems remain as yet almost unsuggested.

SUPPRESSION OF URINE IN PREGNANCY AND THE PUERPERIUM.

ITS RELATION TO SYMMETRICAL NECROSIS OF THE RENAL CORTX.¹

BY ROBERT JARDINE, M.D. EDIN.,

PROFESSOR OF MIDWIFERY, ST. MUNGO'S COLLEGE; CONSULTING OBSTETRIC PHYSICIAN, ROYAL MATERNITY AND WOMEN'S HOSPITAL, GLASGOW;

AND

ALEX. MILLS KENNEDY, M.D. GLASG.,

PATHOLOGIST TO THE GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL.

(Working on Behalf of the Medical Research Council.)

SUPPRESSION of urine is a very rare complication of pregnancy or the puerperium, but it is an extremely dangerous one. It has been my fate to have seen 12 cases, and 6 of these have been proved by post-mortem examinations to have been due to symmetrical necrosis of the renal cortex. Particulars of five of these cases of necrosis have already been published in *The Lancet* and *Journal of Pathology*; the sixth case is described below in full, and also a case of suppression of urine from chronic interstitial nephritis. I have also seen another case of eclampsia with suppression of urine which I believe was one of cortical necrosis, but I was unable to obtain a post-mortem examination of the kidneys. I have not included the case in this paper.

As suppression of urine is an outstanding feature of symmetrical cortical necrosis I append notes of some of those other cases which I have seen from the clinical aspect only, so that they may be compared and contrasted with those that have been proved post mortem. Two occurred during pregnancy, and but one—a partial suppression only—recovered.

CASE 1. Complete suppression of urine at the seventh month of pregnancy; fatal.—Mrs. McA., primigravida, aged 22, about seven months pregnant, was transferred after a few hours in the Glasgow Royal Infirmary to the Maternity Hospital on March 14th, 1906. On admission the patient was conscious but very restless, and frequently asked for a drink. Her right arm was quite limp; the pupils were equal, active, and normal in size. The pulse was 132 and very weak. The heart sounds were pure. The uterus was about the size of a seven months' pregnancy. No fetal heart sounds could be heard. The breech presented. The patient could not give an account of her condition previous to admission, but her husband stated that for three months there had been swelling of the legs and that she had not been able to do housework. During the last two weeks she had complained of dizziness and headache at times. There had not been any convulsions, but her husband had noticed twitchings of her face just before she was taken to the Royal Infirmary. Half an ounce of urine was obtained by catheter. It was heavily loaded with albumin and contained granular casts.

The treatment consisted of free purgation, saline transfusion, and stimulation. The bowels moved freely, but no more urine was excreted. No convulsions occurred. She died ten hours after admission. We were unable to ascertain how long the suppression had lasted, and unfortunately we could not get a post-mortem examination.

There may have been cortical necrosis, but I am inclined to think it was a case of chronic nephritis, similar to Case 11. The three months' swelling of the legs, dizziness, and headache, point to this.

CASE 2.—Partial suppression of urine at 6½ months of pregnancy; recovery.—Mrs. P., primigravida, aged 37, about 6½ months pregnant, was seen by me in consultation with Dr. W. Clow, of Paisley. There had been nothing unusual in the early months of the pregnancy, but on April 7th, 1906, slight bleeding had commenced. The patient was kept in bed for three weeks, and there was a slight "show" of blood all this time. On May 1st swelling of the legs began and slight swelling of the hands and face. By May 5th the swelling had increased, but a careful examination of the urine gave no trace of albumin. Seven days later the urine was found to be heavily loaded with albumin, and to contain tube casts but no blood. The swelling of the legs had increased, and the patient had had headaches occasionally and had vomited once. On May 14th the albumin amounted to 12 per 1000 (Esbach), and on the 16th to 9. She was taking a diuretic and the bowels were being kept freely opened. On May 16th the patient became very excited, and complained of violent headache. About 8 p.m. she became delirious and apparently quite blind. Dr. Clow at once bled her from the arm to the extent of 20 oz. There was immediate improvement of the sight and of the mental condition, and the headache lessened. May 17th: During the night there was much wandering and vomiting occurred seven times. Patient did not know anybody. No urine had been passed since 10 p.m. on the 16th. She was put into a hot pack in the afternoon. I saw her about 5 p.m. She was very

¹ A paper read before the Edinburgh Obstetrical Society on May 12th, 1920.

restless, and continually muttered words which I could not understand. She would not reply when spoken to. No urine had been passed for 19 hours.

She was given 30 oz. of saline solution (acetate and chloride of sodium) under the right breast, and delivered by dilating the cervix by means of Bossi's dilator. There was lateral placenta previa. I did bipolar version and perforated the aftercoming head to lessen the strain on the cervix. There was very little bleeding and no tearing of the cervix. Twelve ounces of urine were obtained by catheter. Next morning 24 oz. of urine were drawn off, and in the evening 36, so the kidneys were acting well and continued to do so. In a fortnight there was only a faint trace of albumin to be found.

In this case there was only partial suppression, but there was a marked toxic effect indicated by the blindness, delirium, and vomiting. There were no fits, but to all intents and purposes it was a case of eclampsia. Dr. Clow probably saved this woman's life by bleeding her so freely. Perhaps it would be more accurate to describe this case as one of marked diminution in the secretion of urine, as there never was complete suppression. I think it was a case of the kidney of pregnancy with very marked toxæmia. If there had been chronic nephritis present I do not think the result would have been so good.

CASE 3. Suppression of urine after Cesarean section; fatal.—The Cesarean section was done for a badly contracted pelvis. When a catheter was passed some hours after the operation 3 oz. of urine were obtained. It was very dark in colour and showed evidence of carboluria. The abdomen had been prepared by a carbolic dressing, and the gauze swabs had been wrung out of a weak carbolic lotion. Next day 9 oz. of urine were obtained. It was clear, but contained albumin and tube casts. Next day 11½ oz. were obtained in 12 hours, and only 2 oz. in the following 13 hours. From that time until death over three days later only 1 drachm of urine was secreted. The albumin had lessened considerably.

Most active treatment was tried, including various diuretics, free purgation, vapour baths, saline transfusion, cupping, and poulticing over the kidneys and bleeding. She gradually became more and more comatose, and there was a distinct urinous odour from her breath. Just before death she had a violent general convulsion which lasted for about one minute.

The pathological examination of this case, which occurred some 22 years ago, was done by Dr. R. M. Buchanan, and the following details are extracted from his report:—

The capsules of both kidneys were slightly adherent, and the cut-surfaces showed well-marked congestion, particularly the pyramidal areas, which contrasted with the pale yellowish but red-streaked cortex. Microscopical examination showed that the tubules of the cortex were almost uniformly dilated, the epithelium compressed, and the lumen filled with granular material. A number of the straight tubules were also dilated and occupied by similar granular material. The malpighian bodies and the blood-vessels appeared normal. The liver showed chronic venous congestion.

From this report it is evident there was chronic nephritis present, but not in such a marked degree as in Case 11. I reported this case to the Edinburgh Obstetrical Society in 1898 (Vol. XXIII. of Transactions). In the many hundreds of Cesarean sections which have been done in the hospital this is the only one in which suppression of urine occurred.

CASE 4. Suppression of urine after a normal labour; fatal.—The patient, a primipara, aged 19, was delivered of a live female child by natural efforts after a labour of 12 hours' duration. On admission a catheter was passed, but the bladder was empty, so no specimen was obtained for examination. During the first few days of the puerperium a considerable quantity of urine was voided, but it was not examined, as it was contaminated with lochial discharge. The patient did not complain, but she had a greyish appearance and looked decidedly ill. She was not septic and the heart and lungs were normal. A catheter was passed on the sixth day of the puerperium, and about ½ oz. of urine was obtained. It showed a deposit of ½ of albumin and a large number of granular casts. Previously to the passing of the catheter the urine had been freely excreted, but from that time onwards there was complete suppression, with the exception of 2 drachms three days later. She died on the fourth day of the suppression. Towards the end the breath had a distinct urinous odour and hiccup and retching occurred. Just before death she had a slight convulsion.

The treatment consisted in the use of diuretics, cupping, hot packs, purging, pilocarpine, and amyl nitrite.

No post-mortem examination was allowed. The presence of the granular casts indicate that nephritis was present. The case was probably the same as Case 11, to be described.

The clinical and pathological accounts of Cases 5 and 6 have already been published in detail in the *Journal of Pathology and Bacteriology*, Vol. XV. (1911), and in the Transactions of the Edinburgh Obstetrical Society, Vol. XXXI. Cases 7, 8, and 9, were fully recorded in THE LANCET, 1913, i., 615, and in the Transactions of the Edinburgh Obstetrical Society, Vol. XXXVIII. The essential features only of these cases are abstracted here.

Nos. 5, 6, 7, 8, 9, and 10 were cases of cortical necrosis and ended fatally.

CASE 5.—The patient, a 7-para, aged 36, was seven and a half months pregnant when she was admitted to hospital suffering from fits, unconscious, and with considerable oedema of face, legs, and lumbar region. The urine was loaded with albumin, becoming almost solid on boiling. She was at once bled to the extent of 12 oz., and 2 pints of the usual saline solution transfused. A hot pack was applied, the stomach

washed out, and salts and chloral hydrate given. Next day 35 oz. of urine were passed containing 1 per cent. albumin and tube casts, and on the following day a dead fetus was born. The urine obtained on this morning contained 0.2 per cent. albumin, but from about mid-day suppression of urine became complete except for the passage of ½ oz. of urine two days later and 1 oz. three days later. Patient was quite conscious and clear mentally by this time, and decapsulation of the right kidney was performed on the following day. Patient became restless after the operation, complaining of abdominal pain, but there were no convulsions. She died ten hours after the operation, there having been about five and a half days anuria.

CASE 6.—The patient, aged 22, was eight months pregnant when admitted to hospital suffering from oedema of feet and legs of several weeks' duration. She had had eight fits during the four hours preceding admission, and with the onset of the fits she had become totally blind. On admission her condition seemed to be very critical. The oedema was marked and the face bloated. She was unconscious, restless, and passed urine and faeces involuntarily. Four more fits occurred in rapid succession. She was bled, given a saline infusion, and a rectal injection of chloral and bromide, and put into a hot pack. The urine was found to contain abundant albumin, a trace of blood, and granular tube casts. She improved somewhat and next day gave birth to a dead child of 4½ lb. Twelve ounces of urine had been passed in 24 hours. On the following day she was worse and the face and extremities were cold and livid, not unlike a degree of Raynaud's disease. She had no more fits, but made no progress, and died some seven days later, the suppression of urine persisting. The suppression was almost but not absolutely complete, as 1-2 oz. of urine were obtained each day.

CASE 7.—The patient, a 9-para, seven months pregnant, was admitted to hospital, extremely blanched and collapsed, suffering from concealed accidental hæmorrhage. There had been oedema of feet and legs for two weeks and abdominal pain for one week before admission. Saline infusion was given and stimulants were administered freely. The patient rallied and in about three hours delivered herself of a dead 3½ lb. fetus. The placenta was unhealthy and the chorion partly adherent necessitating removal. A large amount of blood clot was expressed. The patient improved after delivery, but suppression of urine remained complete from admission. The bladder had been found empty when a catheter was passed on the day of admission, and the patient stated that the last time she passed urine was about 12 hours before admission. The loins were cupped and poulticed, rectal salines administered, and the bowels kept freely open by magnesium sulphate. The complete suppression persisted, but the patient remained quite conscious and suffered no inconvenience except for occasional attacks of dyspnoea. There were never any convulsions, but the dyspnoeic attacks became more frequent and she eventually died four and a half days after the onset of the complete suppression of urine.

Although there had been no convulsions the case was looked upon as being of this nature and the typical eclamptic lesions were found post mortem. A number of other cases in which all the indications of eclampsia were present except convulsions have come under my observation, and in one, which proved fatal, Dr. Kennedy found post mortem the lesions typical of eclampsia. It is interesting to note that this case of suppression (Case 7) was a case of concealed accidental hæmorrhage. By some, toxæmia of pregnancy is held to be the cause of accidental hæmorrhage, and there is no doubt that it is present in some of them.

CASE 8.—The patient, aged 38, 2-para, was admitted to hospital suffering from oedema of feet and legs of six months' duration and bad albuminuria. The urine was loaded with albumin and showed pus cells and granular casts. On the following day live twins of 4 lb. and 4½ lb. respectively were delivered spontaneously. In the next 24 hours only 1 oz. of urine was excreted; the patient's face became oedematous, and persistent vomiting was troublesome. The next day the patient became semi-comatose, and but 1 oz. of urine was excreted. Early in the following morning the patient had a convulsion in which she died. This was the only fit, and the suppression of urine had lasted about 2½ days. The treatment adopted was free purgation, salines by infusion and by the rectum, and free stimulation.

In this case it may also be urged that, as the only convulsion occurred immediately before death, it was not a case of eclampsia, but one of uræmia. From the clinical point of view the case was considered to be one of eclampsia, and the post-mortem findings confirmed this diagnosis.

CASE 9.—The patient, a primipara, 4½ months pregnant, was admitted to hospital under the care of Professor M. Cameron, with oedema of the face of several weeks' duration and severe headache, vomiting, and failure of vision since the day before admission. On the day of admission to hospital she became somewhat comatose, and had several fits. The urine contained so much albumin that it became solid on boiling. The uterus was emptied, two pints of saline given subcutaneously, the stomach washed out, magnesium sulphate and bromide and chloral hydrate administered. There were no more fits, and for two days she kept well and passed a fair quantity of urine. A day later, however, she began to vomit blood, and complained of epigastric pain, and was troubled with hiccup. Vomiting of blood-stained fluid persisted during the following day, and tarry motions were passed. The vomiting ceased the next day, but the hiccup persisted. The urine was now becoming scanty in amount, and some abdominal distension and tenderness over the stomach were observed. By the following day complete suppression of urine had set in, and death ensued a day later, the complete suppression having been under two days in duration.

CASE 10.—Mrs. D., 7-para, aged 48, was admitted to hospital on Dec. 31st, 1918, at 7.40 A.M., having being delivered before admission. She was unconscious and had had seven fits. Shortly after admission she had one fit, but no more. All her other labours had been normal, but in her sixth pregnancy there had been ascites and

albuminuria. The urine had not been examined during the seventh pregnancy so far as we could ascertain. The stomach was washed out, magnesium sulphate administered, and two pints of saline solution given under the breasts. There was no urine in the bladder. The face was puffy, but the legs not much swollen. Mustard and linseed poultices were applied over the kidneys. There was no tenderness in the renal region and the patient did not suffer

FIG. 1.

Kidney from Case 10 (5½ days' suppression of urine), showing the more or less uniform necrosis of the outer two-thirds of the cortex separated from the living inner third by a hæmorrhagic zone. At intervals from this zone of congestion numerous strands pass out to the surface. The necrosed area also involves the interpyramidal cortex. Both kidneys present similar characteristics.

any inconvenience. On Jan. 3rd dry-cupping was tried, and on the 4th both kidneys were decapsulated by Mr. J. H. Pringle. The patient died the next day, the anuria having lasted about 5½ days.

The result of the pathological examination (A. M. K.) was as follows:—

The body is that of a well-developed, well-nourished, fat woman. It is anæmic-looking, and the face looks a trifle puffy, but there is no œdema of the feet or legs, or elsewhere. There are recent operation wounds in both loins over the kidneys.

Head: No gross œdema of the meninges. Blood-vessels healthy, and no thrombosis in any sinuses. On section two small hæmorrhagic foci, of recent origin, each about the size of a lentil, found about the middle of the upper half of the left side of the pons. Nothing further abnormal in the brain. Microscopical examination of sections prepared from the pons confirmed the findings of the P.M.—viz., the presence of two small hæmorrhagic foci. The larger of the two looked as if it were made up of hæmorrhages from several minute foci rather than from one larger focus, as some of them seemed to be surrounded by areas of degenerate brain tissue, demarcating them from the others. A few small capillaries in the neighbourhood of some of the foci were seen to be thrombosed. Microscopical examination of sections from the cerebrum showed nothing of note.

Thorax: Heart is slightly dilated, muscle soft and rather anæmic. Valves healthy and coronary arteries normal. Microscopical examination: Slight general fibrosis of the myocardium.

Lungs: Slight emphysema anterior margins and slight hypostatic congestion and œdema at both bases behind; these findings confirmed later by microscopical examination. Pleuræ appear healthy.

Abdomen: No free fluid present; no hæmorrhages under the peritoneum and no peritonitis. Liver: About normal in size, but appears somewhat fatty. On section, lobules unduly prominent as if there were an excess of interstitial tissue surrounding areas a little larger than a pin's head. No hæmorrhages of any kind under capsule or in substance of liver, and no dilated capillaries visible. Microscopical examination: No areas of focal necrosis or hæmorrhages found, and no thrombosis. Some fatty infiltration present, as shown by fatty globules in the cells at the periphery of a number of the lobules, but of moderate degree only. Capillaries between lobules and in peripheral lobular zones distended in many places, although for the most part somewhat empty of blood. This gave an apparently œdematous look to the connective tissue in these situations and accounted for prominence of lobules noted at the necropsy.

Spleen: Slightly enlarged, pulp full but not septic. Uterus: Evidence shown of recent delivery; one or two small shaggy pieces of placental remains, each a little larger than a pea, still attached to the fundus. Bladder is quite empty. With the exception of the kidneys, all the other abdominal organs healthy.

Kidneys: Both kidneys are somewhat enlarged and show similar characteristics. The capsules have been stripped off completely at operation, and several small pieces of blood-clot are found adhering to the surfaces. The surfaces generally are opaque and pale yellowish-white, but mottled all over with small reddish areas. On section the relative thickness of cortex and medulla appears about normal. The outer two-thirds of the cortex is dull opaque and pale yellowish-white in colour, and apparently completely necrosed. The innermost third of the cortex looks more like living tissue, and is well demarcated off from the necrosed outer two-thirds by a distinct hæmorrhagic zone. At intervals from this zone of congestion small strands of congestion pass into the outer necrosed area, and reaching the surface constitute the reddish mottled areas visible under the capsule. The necrosed area is not confined to the peripheral cortex, but extends into the interpyramidal portion, and everywhere is limited internally by the hæmorrhagic zone, the relations being the same throughout, and a narrow zone of apparently healthy cortex lying immediately next the medulla. At no place can any living tissue be traced passing from the medulla outwards to the surface. The renal arteries are not apparently thickened nor thrombosed, and the pelves and ureters are normal. The condition appears to be one of widespread pale infarction involving approximately the outer two-thirds of the renal cortex, and affecting both kidneys symmetrically.

Microscopical examination: Sections were prepared from several portions of the kidneys and stained with hæmalum and eosin, hæmalum and van Gieson, and carnalum-Gram-Weigert. At the surface immediately under the capsule there is an extremely narrow layer of living tissue, which, however, is not quite uniform. For the most part this layer consists of the fibrous-supporting tissue of the parenchymatous elements, and appears to be in greater amount than normal. It is broken up at many places by the necrosis extending right up to the surface. Between these places, extending a short distance into the kidney, are seen flat wedge-shaped areas in which the parenchymatous elements—tubules and glomeruli—are less necrotic than elsewhere, although many of the tubules are atrophied and a few of the glomeruli appear simply as fibrous tufts. Loose infiltration with polymorph leucocytes is also

FIG. 2.

Microphotograph ($\times 90$) of kidney from Case 10 (5½ days' suppression of urine), showing a dilated and thrombosed interlobular artery near the marginal zone and a thrombosed efferent branch to one of the glomeruli. The section was stained by carnalum-Gram-Weigert specially to show the fibrin. The widespread degeneration of the tubular epithelium, as well as the changes affecting the glomeruli and interstitial tissue, are apparent. Some loose infiltration with leucocytes is just visible.

present. In many of these wedge-shaped areas the capillaries show very marked congestion, and correspond to the small reddish areas seen by the naked eye as mottling the otherwise opaque yellowish-white surface. At no place is there any living tissue connecting the medulla with the surface.

In the infarcted area all the structures are in a stage of practically complete necrosis: the cells have become broken up and granular, and the nuclei have disappeared altogether. The outlines

of tubules and glomeruli, however, are still distinct. The greater part of the infarcted area shows coagulation necrosis without any sign of reaction, except in the marginal zone, where the congestion is present. Here the interstitial tissue around the tubules and glomeruli are loosely infiltrated with polymorphonuclear leucocytes, which, however, only penetrate into the periphery of the paler necrotic areas, in which situation many of the leucocytes are seen to be degenerate also.

In the marginal zone there are much congestion and some hemorrhage. Many of the glomeruli are gorged with blood. As seen by the naked eye, strands of congestion can be traced at intervals passing to the surface, where they form patches of congestion under the capsule. In the marginal zone some of the tubules show a

FIG. 3.

Microphotograph ($\times 90$) of pons from Case 10 (5½ days' suppression of urine), showing one of the hemorrhagic lesions. Some hemorrhage is visible in the centre of degenerate brain tissue. Capillaries in the neighbourhood were found thrombosed.

certain amount of degeneration of their epithelium—the epithelial cells being somewhat granular and their nuclei staining less deeply than usual.

In the infarcted area all the blood-vessels are thrombosed, and share in the general necrosis. Here and there, however, there are some less necrosed, and these are seen to be dilated and plugged with fibrinous thrombi. In the marginal zone bordering the necrotic tissue and in the hemorrhagic strands passing to the surface the interlobular arteries and their branches to the glomeruli are dilated and occupied by thrombi. The thrombi consist for the most part of fibrin. Some of the vessels appear to be filled with dense fibrin; in others the fibrin appears as a filamentous meshwork lining the walls and surrounding apparently living red blood cells in the centre of the vessel. In some others, again, the central part of the vascular channel seems to be occupied by amorphous material in which the degenerate remains of a few red cells can just be made out, whereas at the periphery fibrin is deposited as a lining to the vessel wall. The larger vessels of the vascular arches are not affected. Many of the small straight vessels of the medulla are congested and a number of the medullary tubules appear to contain hyaline casts.

The kidneys had not previously been absolutely healthy organs, for there is some evidence of arterio-sclerotic changes. A number of the arteries show periarterial fibrosis and a few also show slight thickening of the internal coat. In places a few of the glomeruli are seen to be converted into dense fibrous tufts and at the surface a slight increase of the fibrous tissue has already been noted.

CASE 11. Suppression of urine from chronic nephritis; fatal.—Mrs. McD., 3-paras, aged 34, seven months pregnant, admitted at 12.30 A.M. on July 6th, 1919, suffering from suppression of urine, which had lasted for 12 hours. Her family history was good, and she had never had any serious illness except at her previous confinements. At the first confinement (seventh month) she had had several fits, with swelling of the legs and face during the pregnancy and severe headache. The child had lived three weeks. Her next labour had been normal, but she had had one fit. During the present pregnancy she had apparently been well until 24 hours before admission, when her left leg began to swell and the urine was noticed to be scanty; none had been passed for 12 hours. There was slight oedema of the left leg. The lungs and heart were normal. The fundus was at the umbilicus. No urine was obtained.

At the time of admission the os was not dilated, but at 2 P.M. there was a sudden hemorrhage and lateral placenta previa was found to be present. The membranes were ruptured, version done, and a foot brought down. The delivery was left to nature and occurred some eight hours later. There was considerable hemorrhage, checked by ergotin. Two pints of normal saline solution were given and hot packs applied. As there was still complete suppression of urine on the following day Mr. Pringle decapsulated both kidneys within 48 hours of the onset. Both kidneys were curiously mottled and granular in appearance when the capsules were stripped off. 8th: Next day the patient was given 10 grains of diuretin every four hours, but there was no urine secreted. 9th: One ounce of urine was obtained. It contained albumin, red blood corpuscles, and granular casts. 10th: Four ounces of urine obtained. The dressings, which were saturated with urine, were changed, and the drainage-tubes were cleaned and shortened. The patient vomited frequently coffee-ground-like material. Her pulse was very good, and she was quite conscious. 11th: Five ounces of urine were obtained by catheter; it still contained albumin and casts, hyaline and granular. The vomiting continued. Two pints of saline were given under the breasts. The pulse, which had been full and strong throughout, began to fail in the afternoon. Strychnine was given, but the weakening of the pulse continued, and the patient became comatose. She died just after midnight. Ten ounces of urine had been obtained from the bladder since the operation, and in addition the dressings had been saturated with urine.

She was admitted on the 6th at 12.30 A.M. after 12 hours of suppression and died on the 12th, just after midnight, so the suppression had lasted 6½ days. A general post-mortem examination was not allowed.

The result of the pathological examination (A. M. K.) was as follows:—

The kidneys are a little under normal in size and are firm and dense. The surfaces are roughly granular, being studded all over with small rounded elevations of a greyish-yellow colour. The depressions between these prominences are darker. The capsule was apparently somewhat thickened and, although for the most part it has been stripped off, in places it has apparently split leaving a layer adherent to the surface. On section the cortex is seen to be narrowed fairly regularly all round. It is for the most part opaque and greyish-yellow in colour, but mottled with small dark congested areas. The arteriæ rectæ seem congested. The renal arteries are thickened and there is some increase of the fat in the neighbourhood of the renal pelvis.

Microscopical examination showed a general increase of the interstitial connective tissue throughout the kidney and which in places is somewhat cellular and more abundant than in others. Many of the glomeruli show thickening around their capsules and others are completely fibrosed, particularly those near the surface, the tufts being completely converted into dense fibrous nodules. The tubules in the areas where the fibrosis is most marked are atrophied and collapsed and their cells more cubical. In other places many of the tubules are dilated, the epithelium appearing somewhat flattened and granular. The nuclei are for the most part well defined, but are sometimes rather indistinct, and occasionally have disappeared where the epithelium is particularly degenerate. The arteries are slightly thickened and show well-marked peri-arterial fibrosis. The microscopical appearances are typically those of a chronic interstitial nephritis.

Remarks.

When we look at these cases collectively we find this feature in common—that they all suffered from what is known as the toxæmia of pregnancy. The cause seems to lie in the action of a toxin, and if there is chronic interstitial nephritis present there is grave risk of suppression of urine. In the cases of cortical necrosis there is always marked toxæmia present. As to how the thrombosis is brought about I can hazard no opinion.

When suppression of urine is fairly established treatment by medicines, transfusions, &c., seems hopeless. Decapsulation of the kidneys in cortical necrosis has done no good, and one cannot see how it can be of any use. In a case of nephritis, as in Case 11, it might do some good. In that case there was some urine secreted, and the patient lived longer after the operation than any of the cases of necrosis operated upon, but the result was the same.

I am afraid that it is impossible to differentiate between cortical necrosis and chronic nephritis, and it is quite apparent that the two may coexist. A history of previous nephritis would argue against necrosis. The only hope is in prevention, by the careful early treatment of toxæmia of pregnancy.

Summary and Commentary (A. M. K.).

Of the 11 cases noted above, pathological reports on the condition of the kidneys are available in 8 instances. Two of these showed chronic interstitial nephritis only. In the one (Case 11) the condition was well marked—the surfaces of the kidneys being roughly granular, with narrowing of the cortex and thickening of the arteries, and general increase of the interstitial connective tissue throughout; in the other (Case 3) the changes were less

marked, but from the report of Dr. R. M. Buchanan, who made the investigation some 22 years ago, it would appear that the capsules were adherent, the tubules dilated, and their epithelium compressed. The remaining six cases were examples of symmetrical cortical necrosis of the kidneys. In three (Cases 7, 8, and 9) the condition was uncomplicated by any pre-existing disease in the kidneys, the organs showing no changes beyond those associated with the necrosis. In the remaining three, however, the kidneys, prior to the onset of the necrosis, had been the seat of chronic changes of varying degree. The first of these (Case 5), examined by Professor J. H. Teacher, showed that there had been a slight subacute interstitial nephritis pre-existing, the connective tissue in the kidneys being increased in amount and in places rather cellular, and the tubules irregularly dilated. In the second (Case 6), also investigated by Professor Teacher, the old-standing lesion was trifling, there being only very slight endarteritis of the smaller cortical arteries. In the third case (Case 10) the kidneys had been the seat of slight arterio-sclerotic changes. Periarterial fibrosis could be made out and occasionally very slight endarteritis; in places a few of the glomeruli were transformed into dense fibrous tufts, and at the surface little flat wedge-shaped fibrous areas could be made out in which the tubules were atrophied.

From the foregoing series of cases it would appear, therefore, that suppression of urine in pregnancy or the puerperium may be dependent upon chronic interstitial nephritis, or be the result of symmetrical cortical necrosis of the kidneys. Of course, in chronic interstitial nephritis suppression of urine may be met with apart altogether from pregnancy, but symmetrical cortical necrosis would appear to be peculiarly related to the pregnant state. The necrosis may affect kidneys that show no antecedent chronic disease; but old-standing interstitial nephritis or arterio-sclerosis may be present, and, while one is not justified in assuming that the symmetrical cortical necrosis is particularly liable to affect kidneys which are already the seat of chronic changes, it must be recognised that arterio-sclerosis may have some predisposing influence on the occurrence of thrombosis.

Of the six cases of cortical necrosis of the kidneys focal necrosis was found in other organs in five. In three focal necrosis was obvious in the liver, the fourth showed it in the suprarenals and intestines, and in the fifth lesions were found in the pons. No microscopical report on any of the organs other than the kidneys is available in the sixth case (Case 5 of series).

The occurrence of focal necrosis in various organs of the body is one of the features of the pathology of eclampsia, the liver being the organ in which the changes have been most frequently noticed. It would appear, therefore, to be justifiable from the pathological point of view to regard these cases of cortical necrosis as falling into this category. Clinically they were all regarded as being of this nature.

The distribution of the cortical necrosis is noteworthy, involving as it does the outer two-thirds of the cortex. This would appear to have some relation to the vascular supply, for the large vascular arches in the inner part of the cortex are unaffected, whereas the smaller cortical branches are thrombosed.

In the majority of the cases the necrosis is more or less complete, but in Case 9, where the suppression of urine had lasted only $1\frac{1}{2}$ –2 days, the renal lesions were early and give some indication as to how the condition begins. In this case the necrosis in the outer two-thirds of the cortex was of a patchy nature, and the patches were of varying size. Thrombosis of the cortical blood-vessels was not a striking feature. Capillaries in several of the necrotic areas were found thrombosed, but only rarely were any of the arterioles affected. This is rather a striking feature, and contrasts with the other cases of longer duration in which thrombosis was conspicuous, and extended into almost all the cortical vessels above the vascular arches. There is, therefore, some grounds for the view that the thrombosis begins peripherally and spreads inwards towards the proximal end of the interlobular arteries. Professor E. E.

Glynn,² in 1915, describing the pathological findings in a case of cortical necrosis, drew special attention to the presence of blood platelets in the thrombi, particularly in the distal portions, and he considers that the immediate cause of the thrombosis is the deposition of platelets and fibrin in the distal end of the interlobular arteries, their afferent branches, and the glomerular capillaries. He points out that injury to the vascular endothelium is one of the commonest causes of thrombosis, such injury leading to the deposition of platelets and fibrin appearing later. Granted that damage to the vascular endothelium is the immediate cause of the thrombosis, the agency responsible for the damage remains to be determined.

In three of the cases of symmetrical necrosis included in the present series, a certain amount of arterio-sclerosis was present in the kidneys—in two it was very slight, in one it was moderately extensive. The possibility of such arterio-sclerosis predisposing to thrombosis must be admitted, but it is obviously not the prime factor, for in the other three cases no arterio-sclerosis was found. In every case the thrombosis is only found in the neighbourhood of the necrotic tissue, so it would appear that either the one is dependent on the other or both are due to a common factor. Degeneration and necrosis of the renal epithelium are met with in cases of acute nephritis due to causes other than pregnancy, but similar thrombosis is not found in them. It would not appear, therefore, that necrosis of the renal epithelium, per se, produces thrombosis. Further, in fatal cases of eclampsia an almost constant feature is focal necrosis in various organs of the body, but chiefly in the liver, and these are frequently associated with capillary thrombosis. The eclamptic toxin appears to be a very complex body made up of several constituents; hæmolytic (cytolytic), endotheliolytic, and thrombotic elements have all been suggested as component elements. It seems clear, then, how such a toxin could be responsible for the focal necrosis and thrombosis in various organs, and it is only rather surprising that symmetrical necrosis of the kidneys is not more frequently met with. There is the possibility that in the great majority of cases of eclampsia the toxin is modified or altered in some way, perhaps in the liver, before it is excreted by the kidneys, and that it is only in those cases where it passes to the kidneys unaltered or in such concentration as to cause the widespread cortical necrosis and thrombosis in these organs.

Treatment.

The question of treatment of cases of suppression of urine in pregnancy is a difficult one, and will remain so until the whole problem of the pathology of the toxæmia of pregnancy has been solved. We have seen that the suppression may be dependent, on the one hand, upon a chronic nephritis only, or, on the other, upon a symmetrical cortical necrosis involving kidneys which had been quite healthy or were already the seat of chronic changes.

In a recent review³ on "Decapsulation and Nephrotomy for Nephritis" decapsulation and nephrotomy are advocated for those cases of suppression of urine in pregnancy or the puerperium which are due to symmetrical cortical necrosis. It is considered that these cases should be distinguished from eclampsia, and that it is the stillbirth which occasions an acute toxic exudation within the capsule of the kidney causing tension which may be relieved by bilateral nephrotomy and temporary drainage as soon as anuria sets in. The writer of the review does not think time should be spent in medical treatment. We are not inclined to agree with his views. Of the six cases of symmetrical necrosis herein recorded decapsulation was tried in three without effect. Further, the condition is not always associated with stillbirth; one of our cases was delivered of live twins. The writer of the review points out that the operation is useless and contra-indicated for adults suffering from chronic interstitial nephritis. In two of our cases of suppression

² Journ. of Path. and Bact., vol. xix., 1915.

³ Medical Science: Abstracts and Reviews, vol. ii., No. 1, April, 1920.

chronic nephritis was the only condition found post mortem, and in three others of the series symmetrical cortical necrosis was superimposed upon chronic lesions. If the presence of chronic nephritis contra-indicates such operative interference, then the differential diagnosis of suppression due to chronic nephritis and that due to symmetrical necrosis might cause some difficulty. The reviewer urges operation as soon as anuria sets in, but he does not state how long we should wait before concluding that it existed. In Case 9 of our series the suppression of urine had only lasted 1½-2 days, yet the changes found post mortem were such as to be beyond hope of any good resulting from operative treatment at that stage.

We look upon the symmetrical necrosis of the kidneys as being dependent upon the toxæmia of pregnancy and one of the manifestations of eclampsia. The writer of the review, already quoted, urges bilateral decapsulation of the kidneys on the first onset of eclampsia as offering the best chance for both mother and child, and advises delivery by Cæsarean section if the eclampsia be well established. We doubt if many obstetricians will endorse these views. We think that successful treatment will depend upon the earlier recognition of the toxæmic state and the application of such remedies as will eliminate or counteract the toxin before it has caused necrosis of the tissues or vascular thrombosis.

HÆMORRHAGE FOLLOWING THE OPERATIVE TREATMENT OF INTERNAL HÆMORRHOIDS,

WITH PARTICULAR REFERENCE TO SEVERE SECONDARY HÆMORRHAGE.

By W. B. GABRIEL, M.S. LOND., F.R.C.S. ENG.,
HOUSE SURGEON, ST. MARK'S HOSPITAL FOR DISEASES OF RECTUM.

THIS paper is based on an analysis of 500 cases of internal hæmorrhoids operated on at St. Mark's Hospital in the course of the last 16 months. In the table which follows it will be seen that ligature has been performed in 470 cases, including 62 cases in which ligature was combined with treatment for a fissure or fistula. The clamp and cautery method accounted for 18, and Whitehead's operation for 12 cases.

Table of Cases.

Nature of operation and No. of cases.	Variety of hæmorrhage, No. of cases, and No. of days after operation.
Ligature 408	Intermediate ... 2 Secondary-severe 5 (7, 7, 7, 7, 8) Secondary-slight 6 (4, 5, 6, 7, 7, 8)
Clamp and cautery ... 18	Secondary-slight 1 (7)
Whitehead's operation ... 12	Intermediate ... 1
Hds. and fissure (lig. and incision) ... 36	Secondary-slight 1 (10)
Hds. and fistula (lig. and laid open) ... 26	Nil.

Post-operative hæmorrhage may be either (1) intermediate—i.e., within 24 hours of the operation; or (2) secondary—i.e., later than 24 hours after operation.

Intermediate Hæmorrhage.

Of the 3 cases of intermediate hæmorrhage requiring treatment, 2 followed a ligature and 1 a Whitehead's operation. This variety of hæmorrhage is caused by the slipping of a ligature, or by persistent bleeding from a small vessel not ligated at the time of operation or in which the thrombus has become loosened as the result of coughing, vomiting, or straining at micturition. In each case there was considerable oozing during the night following operation, necessitating one or more changes of the outer dressing, requiring active treatment in the morning. Hypodermic injections of morphia were given with general treatment, and the bleeding was controlled efficiently in each case by plugging the rectum by the methods later to be described; a vulcanite tube was inserted in 2 cases, the third was plugged with a rubber tube and a wool "surround." The tubes were removed after 24 hours, and no further bleeding occurred. The routine injection of 5 oz. of sterile olive oil was given into the rectum on the second evening after operation, and castor oil 1 oz. was administered orally on the third morning.

The operative technique is the most important factor in the avoidance of intermediate hæmorrhage. In the ligature operation in particular, care should be taken to keep the scissors accurately in the submucous plane in order to avoid dividing vessels unnecessarily; the distal portions of the ligated piles may be left in situ, or, if part is cut away, an ample amount should be left to ensure that no slipping of the ligature can take place.

No example of intermediate hæmorrhage occurred among the 18 cases treated by the clamp and cautery method.

Secondary Hæmorrhage and Its Causation.

This is an uncommon complication which cannot be anticipated, and unless the possibility of its occurrence is kept in mind, a large concealed hæmorrhage may occur before the condition is recognised. In this series 5 cases of serious secondary hæmorrhage followed a ligature operation, 4 on the seventh and 1 on the eighth day after operation. In addition there were 8 other cases of slight secondary hæmorrhage after defæcation, of no special consequence and requiring very little treatment; 7 of these followed a ligature operation.

A secondary hæmorrhage is brought about by premature separation of the sloughing pile. After the ligature operation the ligatures separate normally between 8 and 12 days after operation. In this series the average date of the secondary hæmorrhage has been seven days after operation. The chief factors in the causation of the hæmorrhage are: (1) Infection, (2) trauma, (3) anæmia and general debility. To these may be added, rarely, (4) blood diseases such as hæmophilia.

1. *Infection.*—This is the most common general cause of secondary hæmorrhage. In the operative technique employed at this hospital every care is taken to render the operation as aseptic as possible. The patient is admitted two days beforehand and efficiently prepared; just before operation the rectum is thoroughly swabbed out with ether soap and lysol, and the piles are swabbed with biniodide in spirit. The bowels are opened on the third day after operation, by which time the raw surfaces should be well covered by granulation tissue. One case of secondary hæmorrhage had a post-operative pyrexia of 101° F., which fell by lysis to normal on the sixth day, and a secondary hæmorrhage occurred on the following day. A post-operative rise of temperature to 99° or 100° F. for a day or two is not unusual, but I do not believe that this pyrexia is necessarily a sign of infection. In none of the cases of secondary hæmorrhage was there evidence of any extraordinary infection, and the cases all healed well, with no ulceration, constriction, fistula, or other sequela. A combination of unusual activity of saprophytic bacteria with diminished resistance on the part of the patient would account for a too early separation of the pile. There might be also a local infective arteritis proximal to the ligature without any actual spreading infection. A slight trauma, such as by the passage even of a soft stool, would then be sufficient to start a hæmorrhage. No case of secondary hæmorrhage occurred among the 26 cases of hæmorrhoids and fistulæ operated on. There was one slight hæmorrhage on the tenth day among the 36 cases of hæmorrhoids and fissures.

2. *Trauma.*—The important exciting cause of secondary hæmorrhage is trauma, usually caused by defæcation. To avoid constipation after operation most cases are put on liquid paraffin with aperients p.r.n., but much difficulty is sometimes experienced in keeping the bowels open satisfactorily. In Case 1 constipation was undoubtedly the important factor in the causation of the hæmorrhage, and in the other cases, although the patients were not constipated, the hæmorrhage was usually first noticed at or shortly after defæcation. Traumatism may also occur from an accidental pull on the ligatures, the ends of which are left long, but I have met with no example of this.

3. *Anæmia and general debility.*—In one of these cases (Case 2) the patient had suffered from severe recurrent bleeding at stool for several months previous to operation, and was evidently in an advanced stage of secondary anæmia. At the operation three large, pale, and friable internal hæmorrhoids were ligatured; a severe secondary hæmorrhage occurred seven days later. In a debilitated individual an avascular pile tends to slough through more rapidly than is normal, there being diminished resistance to bacterial action. It is probably safer to treat such a case by the clamp and cautery method if otherwise suitable.

4. *Blood diseases.*—It is recognised that operations for hæmorrhoids are particularly dangerous in cases of hæmophilia, intractable bleeding taking place at operation and recurring afterwards. There was no suspicion of this disease in any of these cases.

Symptoms and Signs.

There were no premonitory symptoms in these five cases of severe secondary hæmorrhage. The relation of defæcation to the hæmorrhage varied, but usually the bleeding first occurred at or immediately following defæcation. The only local sign was usually a slight intermittent or continuous trickling of blood from the anus, giving absolutely no indication as to the size of the hæmorrhage concealed. In one case a constant tenesmus was complained of, the patient straining down and passing fluid and clotted blood at short intervals. Local pain was usually present, possibly caused by the tension of blood in the rectum, the sphincter being always tightly contracted.

Each case presented to a varying degree the general evidences of loss of blood.

Diagnosis.

If a patient passes a small amount of blood with a stool, he should be confined to bed until the next stool and watched. If there is a small, continuous oozing of blood from the rectum, or a slight recurring hæmorrhage at stool, or the least suspicion of any of the recognised symptoms of hæmorrhage, the insertion of a speculum will infallibly demonstrate whether or not there is bleeding into the rectum with retention.

A Kelly speculum is sterilised, and after lubrication with sterile vaseline is passed gently into the rectum; on withdrawal of the obturator a concealed secondary hæmorrhage, if present, is at once made apparent. A finger passed into the rectum gives no information of any value, and the passage of a small drainage-tube for diagnostic purposes is not to be recommended, since it is liable to be obstructed with blood-clot. The tubular speculum affords the most certain diagnosis.

Treatment.

Local treatment.—The patient lies in the left lateral position and a tubular speculum is then introduced; a varying amount of fluid and coagulated blood will be evacuated. The presence of the speculum may excite expulsive efforts on the part of the patient; in one of these cases the patient suddenly strained down and shot out a large amount of blood when the speculum was passed into the rectum. The lower rectum should be irrigated with one or two pints of normal saline or lysol solution at 110° F. A light is then directed into the speculum, and an attempt is made to localise the bleeding vessel. The sloughs resulting from the operation are usually still present, and, together with the ligatures and entangled blood clot, make identification of the vessel very difficult. The bleeding was definitely arterial in each of the cases of large hæmorrhage, but in only one instance was I able to find the bleeding point; this patient was anæsthetised and the vessel ligated. The remaining four cases were treated by plugging the rectum; this proved quite efficient and should, I think, be successful in all cases; it is easier and quicker than ligation of the vessel, which has to be done under general anæsthesia and is rarely practicable.

Plugging the rectum.—This may be carried out by means of a vulcanite or a rubber tube; an anæsthetic is not required. The vulcanite tube (Gowland's tube) is strong and smooth, 1 in. in diameter and 4 in. long; the end which is passed into the rectum is rounded off, the other end is screwed into an oval vulcanite plate which is pierced at opposite ends to allow of the attachment of tapes. The examination being completed, the speculum is removed. The sterilised lubricated vulcanite tube is passed into the rectum, a little dry sterile wool is packed round it at the anal margin, and it is covered by a large pad of wool secured by a T-bandage. Tapes previously attached to the tube are tied to the bandage round the waist.

Plugging the rectum with a rubber tube is, I think, more efficient, safer, and causes less pain. The method was described by Mr. Lockhart-Mummery, and the plugging is carried out in the following manner:—A piece of stout $\frac{3}{4}$ -in. rubber tubing 5 in. long is boiled and dried; strips of dry sterile wool are then wrapped round it towards one end, making an oval swelling about $1\frac{1}{2}$ in. in its greatest diameter. This is smeared thickly with sterilised vaseline, and the tube with its "surround" of wool is then passed into the rectum. In cases of difficulty I have found it a useful plan first to insert a large-bore tubular speculum, and then to pass in the rubber tube with the wool surround through the speculum. A large safety-pin is passed through

the tube immediately outside the anus, and a gauze strip of the requisite length is wound round the tube, between the pin and the anus, in order to effect some pressure on the pile-bearing area. The large pad of wool and the T-bandage complete the operation. This pad is inspected at short intervals to see that no further hæmorrhage is occurring, and the pulse-rate is recorded frequently.

Local treatment on these lines should control any secondary hæmorrhage from the rectum, however severe. The great merit of the tubes is that any further hæmorrhage is at once revealed, and, if necessary, the plugging can be repeated. Two cases had to be re-plugged, the bleeding being reduced but not completely stopped.

General treatment is carried out on the usual lines.

After-treatment.

The tube is usually removed after 48 hours. An injection of 5 oz. of sterile olive oil into the rectum through the tube serves to facilitate its removal and also to minimise the risk of trauma at the next defæcation. Castor oil (1 oz.) is given by the mouth 6–12 hours later, and the bowels are subsequently kept well open by means of liquid paraffin and suitable aperients. The patients are kept in bed for a week after the hæmorrhage, with treatment for anæmia.

The Five Cases of Secondary Hæmorrhage.

CASE 1.—P. S., male, aged 37. Operation June 16th, 1919. Three hæmorrhoids ligatured; post-anæsthetic vomiting for two days. Constipated in spite of large doses of par. liq. A severe secondary hæmorrhage occurred on June 24th. Speculum inserted and large amount of blood evacuated; brisk arterial bleeding from the right side. The rectum was plugged temporarily, and the vessel then ligatured under anæsthesia and a small tube left in the rectum. Pulse 112. Marked secondary anæmia. Recovery uncomplicated.

CASE 2.—A. R. B., male, aged 29, very anæmic. Operation Oct. 22nd, 1919. Three large avascular internal hæmorrhoids ligatured. Slight post-operative pyrexia; not constipated. Large secondary hæmorrhage on Oct. 29th. No definite bleeding-point seen. Rectum plugged with rubber tube and wool surround; usual general treatment. Pulse 120. Tube removed on Oct. 31st, preceded by an olive oil injection. No further bleeding.

CASE 3.—N. T., male, 36 years. Operation Nov. 27th, 1919. Three hæmorrhoids ligatured. Brisk arterial hæmorrhage on Dec. 4th. Vulcanite tube tied in at 5 P.M. The bleeding did not stop completely, so a rubber tube with a wool surround was inserted at 12.30 A.M., Dec. 5th. Usual general treatment. Pulse 96. Anæmia marked. The tube removed second day. No further bleeding.

CASE 4.—A. R. S., male, aged 44. Operation Dec. 18th, 1919. Three prolapsed and thrombosed internal hæmorrhoids ligatured. Post-operative pyrexia to 101° F., which fell by lysis, and was normal on the sixth day. Severe hæmorrhage on Dec. 25th, but no definite bleeding point seen. Controlled by plugging. Pulse 100. Tube removed second day; no further hæmorrhage occurred. No evidence of local infection.

CASE 5.—B. C., female, aged 28. Three hæmorrhoids ligatured on Feb. 16th, 1920. Secondary hæmorrhage on Feb. 23rd after defæcation. Speculum inserted and bright blood seen escaping, but no definite vessel located. Rectum plugged and usual general treatment given. Pulse 120. Slight oozing continued; rectum re-plugged in evening. No further bleeding; marked secondary anæmia. Tube removed second day.

The cases of slight secondary hæmorrhage require no further note; the bleeding occurred after defæcation on the days indicated in the table. They were treated with hazeline irrigation through a speculum, followed by the insertion of a small drainage-tube for 24 hours, with a little dry wool packing. The patients were kept in bed for four or five days, and no further trouble was experienced.

Conclusions.

1. Severe secondary hæmorrhage following a ligature operation for internal hæmorrhoids is a possible complication, occurring in this series at the rate of just over 1 per cent. of cases—5 in 470. The rectum necessarily becomes a septic area when the bowels are opened three days after operation, and it is difficult to see how the risk of a secondary hæmorrhage from sepsis can be further eliminated.

2. The average date for the hæmorrhage is seven days after operation.

3. The hæmorrhage usually follows an action of the bowels, hence in the post-operative treatment the prevention of constipation is of the greatest importance in minimising the risk of trauma.

4. The bleeding tends to be concealed, and a suspected case of hæmorrhage should be investigated without delay with a tubular speculum.

5. Plugging the rectum with a vulcanite or rubber tube is the most generally efficient method of controlling the hæmorrhage, which is to be combined with suitable general treatment.

I have to thank the surgeons of this hospital for allowing me to record these cases.

THE COMPLEMENT-FIXATION TEST IN GONORRHOEA.

By W. MAGNER, M.B.R.U.I., D.P.H.

(From the Department of Pathology, University College, Cork.)

THE tests upon which this paper is based were carried out in the Pathology Department, University College, Cork. The main objects of the investigation were the determination of the diagnostic value of the reaction and its reliability as a guide to the period of infectivity. If reliable, the test will have a wide application in the diagnosis of obscure gonorrhoeal lesions, especially in the female, and, employed as a criterion of cure, should prove of the utmost value in diminishing the incidence of the disease.

Theoretical Considerations.

The test under consideration has as its underlying principle the detection of specific antibodies in the serum. It would seem therefore that a strongly positive reaction signifying an efficient response on the part of the healthy tissues is of favourable prognostic import. A weakly positive or a negative reaction would seem to indicate a failure of specific antigens in reaching the healthy tissues in sufficient amount, and to suggest the administration of a suitable vaccine in order to provide the necessary tissue stimulus.

Again, a negative result in a case which had previously reacted positively, proving the disappearance of the specific antibodies, would suggest the removal of the tissue stimulus, or in other words, the destruction of the organism. In this respect, however, one must consider the possibility of the gonococcus lying dormant in some situation so walled off from the general circulation that antigenic substances no longer reach the blood-stream and healthy tissues.

To summarise, the points requiring elucidation would appear to be:—

1. Whether in all cases of gonococcal inflammation antibodies can be detected in the serum, or whether such inflammation may exist without the necessary antigenic stimulus reaching the healthy tissues.
2. Whether, when once the tissues are incited to form antibodies, such formation continues until the organisms are destroyed, or whether, the acuteness of the inflammation having subsided, the latter may lie dormant but potentially virulent without exerting any further stimulating action on the body cells.
3. A point of subsidiary importance is the approximate determination of the length of time during which antibodies persist in the serum after destruction of the organism.

The conclusions reached with regard to these points will be discussed.

Technique.

The technique employed was practically identical with that described by Captain D. Thomson, R.A.M.C.¹

Antigen.—During the earlier stages of this investigation Parke, Davis, and Co.'s compound gonococcal antigen was exclusively employed. Later, through Captain Thomson's kindness in providing me with a supply of antigen prepared according to his own method, it was possible to compare the relative merits of the two. It was found by preliminary tests that either antigen in a dilution of 1 in 10 gave satisfactory results, and they were employed in this concentration throughout the work. The conclusions reached as a result of the comparison of the two antigens will be recorded.

Complement.—Guinea-pigs' serum which had been in contact with the clot for three to five hours was employed. The maximum complementary action seems to be attained about this time. The minimum hæmolytic dose was determined in the presence of the antigen. Thus a series of tubes was laid out, to each was added 1 volume (0.25 c.cm.) of a 1 in 10 dilution of the antigen, 1 volume of varying dilutions of the guinea-pigs' serum, from 1 in 10 to 1 in 100, and 1 volume of normal saline solution (to bring the total volume of fluid up to that present in the actual test). The tubes were then placed in the water-bath at 37° C. for one hour, and in the ice-chest for one hour. One volume of sensitised red blood corpuscles was then added, the tubes replaced in the water-bath, and the results read off in half an hour. The highest dilution of the serum which had caused complete hæmolysis was taken as the minimum hæmolytic dose.

In all complement-fixation reactions it is advisable that the complement should be thus titrated in the presence of the antigen. It seems clear that the number of M.H.D.'s of complement absorbed by a given antigen from different sera shows variations. In the majority of cases the antigen in a suitable dilution absorbs between 1 and 1½ M.H.D., but occasionally the same concentration of the antigen will be found to absorb 2½ or even 3 M.H.D. from a given serum. This can only be due to some variation in the complement which renders it more easily absorbed or neutralised. A peculiar fact noted in this connexion is that the presence of normal human serum in the mixture containing antigen and complement diminishes the amount of the latter absorbed. Thus in reading a test it will occasionally be noted that the tubes containing the normal control serum show complete hæmolysis with 3 M.H.D. of the complement, whereas the antigen control, containing the same amount of complement but without serum, shows complete inhibition. The action of normal de complemented serum in preventing the absorption of complement by the antigen is not easily explained.

Red blood cells.—A 6 per cent. suspension of washed sheep's corpuscles in normal saline was employed.

Hæmolytic serum.—This was obtained from Messrs. Burroughs, Wellcome, and Co., and proved very satisfactory. The usual titre was 1 in 3000 and the corpuscles were sensitised with 5 M.H.D. Thus a 1 in 300 dilution of the serum was prepared and equal parts of this and the suspension of red corpuscles were mixed and allowed to stand at room temperature for 15 to 30 minutes before use.

Patients' serum.—This was heated to 60° C. for ten minutes and then diluted 1 in 5 with normal saline.

The Test.

Four tubes were laid out for each serum and four for the controls. In the serum tubes A, B, C, D was placed 1 volume of the diluted de complement patients' serum. To tubes A, B, and C was added 1 volume of the antigen dilution, and to tube D, which acted as the serum control, 1 volume of saline. To tubes A and D was then added 1 volume of guinea-pig's serum, containing 2½ M.H.D. of complement, to tube B, 1 volume containing 3 M.H.D., and to tube C, 1 volume containing 3½ M.H.D. The control tubes were arranged as follows:—

- | | |
|--|-------------------|
| (1) 1 volume of normal de complemented serum (1/5) plus 1 volume of antigen plus 2½ M.H.D. of complement | Negative control. |
| (2) 1 volume of a positive serum plus 1 volume of antigen plus 2½ M.H.D. of complement | Positive control. |
| (3) 1 volume of saline plus 1 volume of antigen plus 2½ M.H.D. | Antigen control. |
| (4) 3 volumes of saline | Red cell control. |

The whole series was then placed in the ice-chest overnight about 16 hours. On the following morning to each tube was added 1 volume of sensitised red cells; the tubes were then replaced in the water-bath and the results read as soon as the serum controls and the antigen control showed complete hæmolysis.

The rule observed in reading the tests was that a serum showing complete inhibition of hæmolysis in the first two tubes and partial or complete inhibition in the third was marked Strongly Positive (+++). A serum showing complete inhibition in the first tube and partial or complete inhibition in the second was marked down Positive (++) . A serum showing complete inhibition in the first tube and complete hæmolysis in the others was marked Weakly Positive (+ + -). Sera which showed partial hæmolysis in the first tube and complete hæmolysis in the others was marked Doubtful (± - -), and, if possible, re-examination was carried out after an interval.

Number and Types of Cases Examined.

The total number of sera examined was 200, comprising 110 actual cases of disease and 90 controls. All collected from male patients. In the majority of the cases the subsequent history was available, and the extent to which this confirmed the results of the tests could be determined. A large number of the sera were examined simultaneously with Thomson's and Parke, Davis, and Co.'s antigen, so that the actual number of tests carried out was 298. The cases were grouped as follows:—

Group 1.— <i>Urethral discharge containing gonococci.</i>	
(a) Acute purulent discharge	60 cases.
(b) Chronic gleet discharge	20 "
(c) Cases with discharge and systemic complications	4 "
Group 2.— <i>Urethral discharge without gonococci.</i>	
(a) Gleet with a definite history of previous acute discharge containing gonococci	10 "
(b) Similar cases with systemic complications	2 "
(c) Cases of doubtful nature	2 "
Group 3.— <i>Apparently cured cases which had received treatment with ordinary autogenous vaccines</i>	
	5 "
Group 4.— <i>Apparently cured cases which had not received vaccine treatment</i>	
	7 "
Group 5.— <i>Controls, comprising cases of syphilis, non-venereal diseases, and normal individuals</i>	
	90 "

¹ Medical Research Committee, Special Report Series, No. 19.

Results.

GROUP 1 (a).—Acute Purulent Discharge Containing Gonococci.

Date of collection of serum.	Total tested.	Pos.	Neg.	Doubtful
Before 12th day of discharge	9	2	6	1
Between 12th and 24th day	21	17	3	1
" 24th " 50th "	30	27	2	1

In 51 cases in which the serum was collected after the 12th day of the discharge 88 per cent. of positive results were obtained.

GROUP 1 (b).—Gleety Discharge Containing Gonococci.

Date of collection of serum.	Total tested.	Pos.	Neg.	Doubtful
Between 4th and 5th week	3	2	—	1
" 5th and 10th week	5	5	—	—
After 10th week	12	11	1	—

In 20 cases in which the serum was collected after the 4th week 95 per cent. of positive results were obtained.

GROUP 1 (c).—Cases with Discharge and Systemic Complication.

Date of collection of serum.	Total tested.	Pos.	Neg.	Complication.
5th week	1	1	—	Epididymitis.
7th "	1	1	—	"
3rd month	1	1	—	"
5th "	1	1	—	Arthritis.

In 4 cases with systemic complications 100 per cent. of positive results were obtained.

GROUP 2 (a).—Gleety Discharge. No Gonococci. Gonococci Previously Detected.

Date of collection of serum.	Total tested.	Pos.	Neg.	Doubtful
8th week	3	2	—	1
10th to 13th week	5	4	—	1
4th month	1	1	—	—
5th month	1	—	1	—

In 10 cases in which the serum was collected between 2nd and 5th month, 7 positive, 2 doubtful, and 1 negative result were obtained.

GROUP 2 (b).—Cases Similar to Previous Group but Complicated by Arthritis.

Date of collection of serum.	Total tested.	Pos.	Neg.	Complications
8th month	1	1	—	Arthritis.
15th week	1	1	—	"

In two cases with arthritis and a history of gonorrhoea positive results were obtained.

GROUP 2 (c).—Cases of Doubtful Nature.

Date of collection of serum.	Total tested.	Pos.	Neg.	Remarks.
11th day	1	—	1	Mucoid discharge, denies possibility of gonorrhoea.
14th "	1	—	1	Purulent discharge. <i>B. coli</i> and Staph.

In two cases in which the history appeared to exclude gonorrhoea negative results were obtained.

GROUP 3.—Apparently Cured Cases which had been Treated with Autogenous Vaccines.

Date of collection of serum.	Total tested.	Pos.	Neg.	Doubtful
1 month after treatment had ceased	1	1	—	—
10 weeks " "	2	1	—	1
3 months " "	1	—	1	—
18 weeks " "	1	—	1	—

Three cases tested within three months of the date of last injection gave two positive and one doubtful result. Two cases tested after an interval of three months gave negative results.

GROUP 4.—Apparently Cured Cases which had not Received Vaccine Treatment.

Date of collection of serum.	Total tested.	Pos.	Neg.	Doubtful
Between 1 and 2 months after discharge had ceased	2	2	—	—
Between 2 and 3 months	2	1	1	—
Between 3 and 4 months	3	—	3	—

Two cases tested within two months after all symptoms had disappeared gave positive results. Five cases tested after the second month gave four negative results.

GROUP 5.—Controls.

Nature of case.	No.	Pos.	Neg.	Doubtful
Syphilis (Wass. pos.)	20	3	17	—
Cured syphilis (Wass. neg.)	39	1	38	—
Suspected enteric	10	—	10	—
Malaria	4	—	4	—
<i>B. coli</i> septicæmia	1	—	1	—
Normal individuals	16	—	15	1

Four positive results were obtained amongst 90 controls. Of these 4 cases one admitted having gonorrhoea eight years previously, but denied any recent infection. The other 3 denied ever having had gonorrhoea.

Comparative Tests with the Two Antigens.

(a) To determine relative degree of specificity.

Number of sera tested with both	98
Number positive with both	34
Negative with both	60
Positive with T., negative with P.D.	3
Positive with P.D., negative with T.	1

(b) To determine anticomplementary action.

To determine the anticomplementary action of the two antigens the M.H.D. of a guinea-pig's serum was estimated. Thus, a series of tubes was laid out; to each was added 1 volume of varying dilutions of the serum, 2 volumes of normal saline, and 1 volume of sensitised red cells. The tubes were then placed in the water-bath at 37° C. and the result read in half an hour. The highest dilution showing complete hæmolysis was taken as the M.H.D.

Two further rows of tubes were then laid out. To one row was added 1 volume of Thomson's antigen, and to the other 1 volume of Parke, Davis, and Co.'s antigen. One volume of saline was then added to each tube, and, starting at the left-hand tube in each row, 1 volume of varying dilutions of the serum. The tubes were then placed in the water-bath for one hour, and in the ice-chest for one hour. One volume of sensitised red blood cells was then added to each tube and the series replaced in the water-bath.

The result was read in half an hour, and by contrasting the M.H.D. with that determined by previous estimation the number of doses absorbed by the antigens could be determined. As a result of 15 such tests it was found that Thomson's antigen in a dilution of 1 in 10 never absorbed more than one M.H.D. On the other hand, Parke, Davis, and Co.'s antigen never absorbed less than one and a-half, and occasionally absorbed two M.H.D.

Thomson's antigen invariably proved less anti-complementary than P., D., and Co.'s. It would also appear to be slightly more sensitive, though here the difference is not very marked.

Review of Results.

As in all complement-fixation reactions the reliability of the test must depend to a great extent upon the sensitiveness of the antigen. Both antigens employed in this investigation gave satisfactory results, but more accurate information as to the serological strains of the gonococcus is desirable so that a definitely polyvalent antigen may be prepared. A negative result in the early stages of the attack is of no significance. A considerable proportion of cases during the first fortnight gave such result. The greater the duration of the discharge the greater the probability of a positive result. After the third week the great majority of cases reacted positively. The occurrence of systemic complications, such as epididymitis or arthritis, was invariably associated with a positive reaction. This is to be expected, as such complications indicate the dissemination of the organism and presumably a specific response on the part of the infected tissues.

Cases in which gonococci are found or can be induced to appear in the discharge offer no difficulty in diagnosis, and of course as long as the organism is present the patient is warned that he is infective. In many cases, however, as soon as the acuteness of the attack has subsided the organisms disappear, though a more or less scanty mucoid discharge persists. It is cases of this type which prove a serious problem for the practitioner, as he is frequently called upon to decide whether the patient is non-infective and at liberty to marry. A decision based upon negative microscopical examinations is fraught with danger, and it would seem that the complement-fixation test is of very real value in such cases. A positive result indicates either that the patient still harbours the gonococcus or that the latter has been so recently destroyed that antibodies still persist in his serum. In the latter case the positive result will disappear within a few months. The indication in such a case is to warn the patient that he is still infective, to continue local treatment, and to re-examine the serum after an interval of three months.

A negative result, especially if the serum has previously given a positive reaction, is very strong presumptive evidence of the destruction of the organism. It is, however, obvious that a much more extended investigation is necessary before the value of the test in this direction can be definitely established. Antibodies seem to disappear somewhat rapidly after the elimination of the organism. Positive results were obtained up to the third month after disappearance of all symptoms. After the third month all cases treated gave negative results.

The administration of an ordinary autogenous vaccine does not appear to prolong the positive stage to any great extent. A negative result is therefore not to be expected until three months after disappearance of symptoms and cessation of treatment, but a change from positive to negative about this time indicates complete cure and non-infectivity.

Four positive results were obtained amongst 90 controls. These positive cases were either suffering from or had suffered from syphilis. One admitted an attack of gonorrhoea eight years previously. One doubtful result was obtained in a healthy individual who had no history of gonorrhoea. It is noteworthy that the only controls giving positive results were those who admittedly had run the risk of contracting gonorrhoea, though denying any recent infection.

Conclusions.

1. The complement-fixation reaction will prove of real value both in the diagnosis of gonorrhoeal infections and in the determination of the period of infectivity.
2. It is probable that with more accurate information as to the serological types of the gonococcus a more sensitive antigen will be available and still more specific results obtained.
3. Negative results are common during the first 10 or 12 days of the discharge. After this period the great majority of cases react positively. Positive results may, however, be obtained as early as the fourth day.
4. A certain number of mild cases in which the infection appeared to be limited to the anterior urethra reacted negatively through the attack.
5. The more extensive the inflammation the greater the probability of a positive result. Cases showing systemic complications invariably give such a result.
6. The complement-fixing antibody persists in the serum for about three months after destruction of the organism, during which period the reaction remains positive.
7. The administration of an autogenous gonococcal vaccine during the course of treatment does not lead to a greater persistence of antibodies, the serum becoming negative in about the same period after the final injection.
8. The criterion of cure and non-infectivity is therefore a change in the reaction from positive to negative three months after disappearance of all symptoms and cessation of all treatment.

REMOVAL OF METALLIC FOREIGN BODIES

BY SURGICAL OPERATIONS UNDER DIRECT
X RAY CONTROL.¹

By C. FRED. BAILEY, M.D. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN AND MEDICAL OFFICER IN CHARGE ELECTRICAL
DEPARTMENT, ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

As a result of five years' experience as radiologist at the 2nd Eastern General Military Hospital, where I assisted at a large number of operations carried out under direct X ray control, I wish to appeal for the more frequent use of this method. The removal of foreign bodies is rendered easy and sure, the average time of operation is appreciably reduced, and the after-results are excellent. X ray apparatus should, however, be simple; both surgeon and anaesthetist object strongly if their work is impeded by a cumbrous or complicated X ray plant, and would prefer an X ray operating table as little different as possible from the ordinary operation table, leaving a perfectly clear field for the operation. Moreover, the day when an operating surgeon took but a perfunctory interest in the methods by which a radiologist supplies him with certain X ray data is past or is rapidly passing. The operator now often consults with the radiologist beforehand in the X ray room, using the ordinary apparatus, on the different indications of the position of a metallic fragment, and as to the steps of a projected operation. This consultation has developed into quite a rehearsal of the operation itself; therefore, to introduce a new complication in the shape of different X ray apparatus must be a mistake. For the control operations the best X ray plant is that ordinarily used, except in quite exceptional cases. However, while I maintain the superiority of the simple type of equipment, it must be an *efficient* type; it must be capable of producing perfect skiagraphs, able to show good stereoscopic views, and equal to very rapid localisation work. Many civil hospital equipments are by no means up to even this moderate standard.

Cases which have been operated on, perhaps several times over, without successful removal show such severe damage in the form of excessive scar tissue, and disability resulting from unsuccessful search, as to convince me that the common X ray help given the surgeon, by X ray plates and surface markings, is often insufficient, and that a preliminary consultation with the radiologist in the X ray room would have saved these patients much trouble. Some have been operated on by routes that surely no surgeon would have adopted had he possessed a clear and correct idea of the foreign body's exact position. Of course, it may be argued that in some cases the position of the fragment might have changed or that the position of the patient might have been different when X rayed to that when under anaesthesia at the operation. Both these contentions, to my mind, would merely be strong arguments in favour of preliminary combined observation by surgeon and radiologist.

The Essential Equipment for Direct-control Operations.

The essentials of a suitable equipment are, in my opinion: (1) Freedom from the possibility of "shocks" to patient or anyone near; (2) X ray protection for all, as thorough as can be, added to simplicity of apparatus; and (3) rapidity and ease of manipulation of apparatus. The main points of distinction in my equipment are: (1) A simple five-ply wood-topped X ray table without castors, light, and easily moved into any position, having no rails or tube-box, in fact, nothing whatever attached to it; (2) a light oak tube-stand on very easy castors; its tube-box can be moved about under the table by a handle held by the radiologist, who stands at the same side of the table as the surgeon, while the tube-stand itself remains on the opposite side; and (3) satisfactory X ray protection, no danger of "shocks," no liability of damage to machinery or individuals when working in the dark. It will be seen that the factors (1) and (2) give an absolutely clear field for operating.

¹ Abridged version of a paper read before the Brighton and Sussex Medico-Chirurgical Society on April 1st, 1920.

Obviously, an X ray room should be large (say, with a superficies of 500 sq. ft. and height of 12 ft.), with large windows, allowing plenty of daylight, and "through" ventilation after operations; steam radiators and electric stoves maintain a proper temperature. Walls and ceiling distempered a dull dark red allow light rays of a complementary colour to that of the fluorescent screen alone to affect the retinae of operator and radiologist; the screen-observers can then quickly pick up the "screen-picture" when lights are turned out. Artificial light is used almost solely, but anaesthetists require that the room can be flooded with daylight and filled with fresh air at a moment's notice if necessary.

In "direct control" work the daylight and artificial lighting of the X ray room are supremely important. Blinds should fall to let daylight in and rise to shut it out. Window space must allow it to be filled with daylight when blinds are down, and blinds must be so opaque and well-fitting as to maintain absolute darkness when they are up. The darkness must be so complete that after a five-minute interval one cannot see a glimmer of light entering anywhere, nor any of the objects in the room. I prefer

placed anywhere under the table (except on a very small area near each of two of the table legs), and, if necessary (for example, with an arm on a splint at right angles to the body), the screen examination can be carried out even beyond the limits of the table itself. Now, with a tube-box fixed on rails under a table, the combined weight is too great to move; no work outside the table is possible, while the workable area of a table is a much restricted one, and the rails and the box are often in the surgeon's way. A tube-stand need only be brought to the table when wanted, and, when unwanted, can be shifted into safety at once.

The light tube-stand has a very useful property due to its easy movement. It is difficult, sometimes, to make out a foreign body clearly, if it be deep-seated and its shadow involved in the shadow of large bone masses, or should the body be of thin metallic casing; but, if a series of very short and rapid side-to-side movements are made with the handle, then (for the reason that the parallaxic movements of shadows of different structures under fluorescent-screen examination vary in amplitude in accordance with these structures' different depths) the foreign body will stand out with a distinctness much greater than if the tube be at rest.

Lateral view of tube-holder. ("Lead-rubber" apron removed.)

walls and ceiling dark red rather than black, as daylight illumination is better, and it suffices if no colour rays similar to fluorescence rays reach the retina and tire it for the screen.

For artificial lighting one powerful electric light should hang over the table for the surgeon, its exact position to be indicated by him; it should be shaded, so that no direct white light is on his eyes, which receive only reflected light from the patient's body and the X ray table. A weaker light beside it, also shaded, is for substitution when strong light is not needed; another weak light hangs over the anaesthetist; the other room lights are also shaded to protect the eyes of the surgeon and radiologist.

Good illumination of the operation field, if the surgeon's and radiologist's heads remain in darkness, or at least in reflected light only, does not prevent both seeing quite well all details on the screen directly lights are off and X rays started. Red-glass goggles for the surgeon have been advised, but they are not comfortable, and, in my opinion, may cause failure in asepsis.

The wooden X ray table, which must be strong, light, and steady, can be put in any position desired. The tube-stand, of oak, with heavy iron foot, on easy castors, is supplied with X ray proof box and three diaphragms. We were able to increase X ray protection by doubling the tube-box's lead-rubber lining and hanging on to the box a lead-rubber apron. A large wooden handle, hinged to fall down and giving a firm grasp, fixed to the box opposite its attached side, made the stand manipulable from the opposite side of the table. The changing of diaphragms, as supplied, occupied too much time for us, so we retained the 3-inch one for regular use and added other circular lead ones, with bevelled edges fitting in the 3-inch aperture and apertures of their own down to 1/2-inch; they were dropped into position or removed in a moment without danger of shifting the position of the tube-box.

The Separate Movable Tube-stand.

The separate light movable tube-stand (see figure) and light X ray table have many advantages over a heavy table with tube-box attached to it, for, besides being suitable for overhead work and emergency ward work, both table and tube-box are easily portable. Moreover, the X ray tube can be

The light tube-stand was discovered to be more rigid and free from "vibration trouble" than our heavy iron one; but "vibration trouble" is, in my experience, usually due to the shakiness of a plank flooring. A solid parquet floor gives none; a parquet floor, correct methods of connexion of tube-box and coil, and all possible accidental earths far from the table together make shocks also impossible. For ease in tube-changing, tube-testing, centring, working with an oblique ray the separate tube-stand is incomparable.

Should the X ray evidence of his preliminary examination convince the radiologist of the necessity of a "direct control" operation, he must give his surgeon a demonstration in the X ray room. This demonstration should include exact localisation of the metal fragment in reference to skin surface and to structures near; a stereoscopic view and the section illustrations in Symington's Atlas will also help. After this the surgeon ought to have as clear a mental picture as his colleague of the foreign body's position; he can then exactly mentally visualise the sequence of his operative events and, by arranging all details in advance, save time at the actual operation.

The operative steps must, of course, vary according to the particular case, but usually bull-dog forceps mark the vertical line and horizontal plane of the metal body; the surgeon's skin-incision is at his own selected spot. The surgeon's educated sensitive finger, superior to any mechanical device, pressing the lump he feels, disturbs the fragment's shadow on the screen, and when the point of a pair of forceps are demonstrated by the method of parallax to be in contact with the foreign body, its capsule is cut into and it is removed. In the method of parallax shadows of fragment and forceps-point are made to coincide in the centre of the circle of light, and the tube-box handle is then swung to the right; if the shadows separate the left one is deeper, if they do not the two objects are touching.

Two points of value in direct control work are: (1) Easy removal of several fragments through one incision; and (2) the certainty a final inspection gives that all metal has been removed.

Certain Objections.

The objections raised are various: surgeons start off by claiming inability to see anything on the screen, but it is found that practically everyone can with ten minutes'

practice see all the details of the fluorescent-screen picture. The presbyopic men must use their glasses for near vision. Secondly, it is contended that operations with the screen are dangerous. The obvious answer is that if any X ray room is dangerous, then the radiologist is very blameworthy in not having tested its safety and remedied it, while he is the person who is by far the most likely to suffer. A third objection is that asepsis cannot be maintained. It certainly can be. The direct control cases did better than the ordinary operating theatre ones in our experience. Besides, the X ray room, with nitrogen peroxides from electric discharges always in evidence, is a spot not favourable to pathogenic germ-growth. The final argument that there is no real necessity for direct control operations is quite untenable. Five years' military hospital experience of much-operated-on patients still carrying their shell fragments unfortunately proved their necessity.

Summary.

(1) The removal of foreign bodies by preliminary mutual consultation, followed by an operation under direct X ray control has been, and will still be in the future, a necessity in certain cases. (2) A direct X ray control operation can be carried out successfully with ordinary equipment. (3) The after-results of such an operation are found to be satisfactory. (4) The practice of direct X ray control operations for the removal of metallic foreign bodies is one to be recommended in general, and especially will be required so long as cases remain who present disability due to their continued presence.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

INFECTION WITH THE ORGANISMS OF VINCENT'S ANGINA FOLLOWING MAN-BITE.

By P. H. HENNESSY, M.B., C.M. MADRAS,

MEDICAL OFFICER IN CHARGE, GENERAL HOSPITAL, KUALA LUMPUR; AND

WILLIAM FLETCHER,

PATHOLOGIST, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR, FEDERATED MALAY STATES.

MANY years ago Babes, Plaut, Vincent, and others described a disease which usually begins as an acute stomatitis or tonsillitis, and may lead to the formation of a membrane resembling diphtheria. In the lesions they found spindle-shaped or fusiform bacilli associated with spirochaetes. This disease is now known as Vincent's angina. Taylor and McKinstry,¹ who investigated its occurrence amongst soldiers, found that the characteristic lesions were always preceded by a localised, peridental, or marginal gingivitis. More recently Semple and others,² as the result of the examination of a large number of persons, concluded that fusiform bacilli and spirochaetes are normal inhabitants of the healthy buccal cavity.

The occurrence of these organisms is not limited to the mouth and throat. Vincent found fusiform bacilli, together with spirochaetes, in hospital gangrene, and in 1896, at the Académie de Médecine, he stated that they were the cause of tropical phagedæna. They have been found in noma and in erosive balanitis and vulvitis. Dick³ has reported the presence of fusiform bacilli in three cases of meningitis in which the infection probably arose from the middle ear. Heyde,⁶ in an examination of 102 cases of appendicitis, found fusiform bacilli in 8. Luger⁷ has found spirochaetes and fusiform bacilli in the stools. Peters⁴ found them in a case of lung abscess and in another of fetid bronchitis. Recently Blanchard⁸ described a number of cases of phagedæna complicating vaccination pustules, which was due to spirochaetes and fusiform bacilli.

The infection of wounds caused by the teeth has been reported by Peters.⁴ In one instance a labourer

injured his fingers by striking a man in the mouth. The injury was followed by intense swelling, œdema, and a foul discharge in which fusiform bacilli were discovered in association with streptococci, but without spirochaetes. The same author describes the case of a bar-tender who hit a man in the mouth and injured his own hand. Despite free incisions and soaking in antiseptic lotions there was deep destruction of tissue and the hand did not heal for 54 days. In this instance great numbers of spirochaetes were associated with the fusiform bacilli. Peters also mentions the case of a 7-year-old child who suffered from partial gangrene of one of her index fingers as the result of infection with spirochaetes and fusiform bacilli attributed to the child's habit of biting her nails with her carious teeth.

Details of Case.

Our patient, C. P., a Tamil, was in charge of a small plantation where, one day, he caught a Malay stealing some of the rubber crop. The Malay fought savagely, bit the Tamil severely in the forearm, and then seized his left thumb between his teeth and bit it with such force that the nail was torn off and the terminal phalanx was fractured. When the patient was admitted to hospital in Kuala Lumpur a fortnight after the fight, the whole thumb was

Pus film from the patient's thumb. Stained by Fontana's method. There were very few fusiform bacilli in this film.

swollen and indurated; where the nail should have been there was only a soft mass of granulation tissue with sinuses leading down to the fractured phalanx, and at the base of the thumb there was an abscess which involved the metacarpo-phalangeal joint. The patient's temperature was slightly raised, but it fell to normal when the abscess was opened.

The pus from the sinuses contained fusiform bacilli and enormous numbers of spirochaetes in writhing, tangled masses. These spirochaetes were of several types and sizes. At one end of the scale there were large, actively motile organisms of the *refringens* type, which probably corresponded with Semple's² *Spirochaeta buccale*, and at the other end there were very minute active spirochaetes, smaller than *S. pallidum*, but with the same regular coils. Between these extremes there were two other forms which were probably the same as those described by Semple under the names of *S. medium* and *S. dentium*.

Tubes of serum agar were inoculated by introducing plugs of cotton-wool, which had been soaked in the discharge, into the bottom of the medium (as recommended by Semple), and a growth of spirochaetes was obtained in mixed culture. Fusiform bacilli were also grown from the discharge by the method of Krumwiede and Pratt.⁵

Inoculations with the discharge from the thumb were made subcutaneously and into the testes of a rabbit, but it remained healthy. The experience of others has been the same; Blanchard,⁹ for instance, found that the organisms of Vincent's angina do not multiply when they are inoculated under the healthy skin but only after it has been injured, as, for example, by an escharotic, such as caustic potash.

Vincent's angina does not cause a positive Wassermann reaction. In our case the patient's serum gave a slight positive reaction, but this was probably due to syphilis, for he admitted that he had suffered from a chancre ten years before.

Louis Rousseau¹⁰ states that tropical phagedænia due to spirochaetes and fusiform bacilli can be cured in about a week by three injections of 0.3 g. of nov-arsenobillon given on the first, fourth, and seventh

days. In our patient the thumb-joints were disorganised, the phalanges and the distal end of the metacarpal bone were necrotic; the disease had gone too far, and the pain was so severe that amputation was imperative. The patient was given two injections of 0.6 g., and after the operation he made an excellent recovery.

The main feature of this case and of that reported by Peters, is the widespread destruction of tissue (which in our patient involved the bones), resulting from an infection with spirochaetes and fusiform bacilli.

A CASE OF PHOCOMELUS.

BY CAWAS HOMI, M.B., B.S. BOMBAY, M.R.C.S., ENG.,
L.R.C.P. LOND.

THIS type of monstrosity in mankind being comparatively rare, I think this case will be of interest to teratologists and the medical profession in general. Phocomelus is one of the sub-varieties of the monsters of the genus ectromelus (ἐκτρώμα, from ἐκτιρώσκω, to abort or miscarry, and μέλος, a limb), a monstrosity in which the limbs are nearly or altogether deficient from an arrest of development as distinguished from spontaneous amputation. This name was given by the celebrated anatomist, Isidore Geoffroy Saint Hilaire, in 1832, who subdivided ectromelus into amelus, phocomelus, hemimelus, and ectrodactyly. The term amelus is restricted to the cases in which all the four limbs are absent, whilst the phocomelus foetus is one in which the proximal and not the distal segment of one or more limbs is aborted, thus contrasting markedly with hemimelus, in which the distal segment is the part affected. In phocomelus the foot or hand seems to spring directly from the trunk, giving the extremity or extremities the appearance of the flippers of the seal (phoca). Ectrodactyly, a lesser degree of deformity of the genus ectromelus, shows a rudimentary hand in which the phalanges are represented by small tubercles.

Further reference to these varieties is found in Ballantyne's "Ante-Natal Pathology and Hygiene," with good illustrations and explanations. Cases of ectrodactyly are described by Dr. E. Cautley and Dr. J. D. Rolleston in the Transactions of the Royal Society of Medicine.¹

Description of Case.

This phocomelus child was brought to the out-patient department of the Belgrave Hospital for Children for fits, and was admitted for observation, X ray examination, and photograph. He was well built,

8 days old, and showed no associated abnormality or malformation common in these monstrosities, such as umbilical, inguinal, or diaphragmatic hernia, cleft-palate, hare-lip, undescended testicle, dextrocardia or malformation of the heart, imperforate anus, spina bifida, and so forth. The umbilical cord had not yet dropped, and was black and dry. Head measured 15 inches, and its appearance suggested some internal hydrocephalus, to which I attributed the fits. The child cried vigorously.

On inquiry I found this monster was born as footling of healthy parents on March 24th, the mother having been in labour for eight hours. The period of gestation was estimated at 41 weeks, the mother having had her last menstrual period on June 10th, 1919. Father, 42 years old, is a sailor; the mother, aged 42½ years, has had three other normal healthy children (one boy and two girls, aged 16, 14, and 9 years respectively). One miscarriage in 1912 and no further pregnancy till this year. The mother attributed the child's deformity to her having seen, when about six weeks pregnant, a

discharged soldier in a fit which lasted over half an hour. She saw him lying on the ground unconscious with twitching of the face, his arms adducted to his sides, forearm flexed at the elbow, and hands alternately hyperextended and flexed at the wrist. She went to his help and tried to lift him up, but she herself was feeling bad and giddy and dropped down on the floor: she was picked up and taken to her room, where she lay ill in bed for two weeks. She had a constant dread lest she might give birth to a child who might suffer from fits like the soldier, and she would wake up at night hearing and seeing a man in a fit.

For three days after the child's birth she was very excited, disliked the baby, and did not care to feed him. When four days old the child had a fit and became very blue, so the father brought him to the hospital. The child was in the hospital for a week and had fits daily, some of them severe, prolonged, and accompanied by cyanosis. The father was told that there was no hope for the child, and took him home; and death occurred during a fit when 20 days old. Unfortunately a post-mortem examination was not obtainable.

Theories of Causation.

There have been many theories propounded as to the causation of these monstrosities. In ancient times supernatural factors were invoked; some teratologists attribute them to intra-uterine conditions, such as amniotic pressure, adhesions, bands, and intra-uterine amputation, but I am inclined to believe that the chief factor in the causation of the malformation in this case was the strong maternal impression, which led to the arrest of the ontogenesis in the embryonic and neonatal stage of existence of this child.

In conclusion, I wish to record my indebtedness to Dr. Cautley for his valuable assistance and permission to publish this case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A MEETING of this section of the Royal Society of Medicine was held on July 8th, Mr. J. D. MALCOLM, the retiring President, being in the chair.

Exhibition of Specimens.

Dr. J. D. BARRIS showed a specimen of Primary Carcinoma of the Fallopian Tubes in a 3-para of 53. The menopause occurred three years ago and she was well till November, 1919, when she began to have repeated hæmorrhages. When she was operated on in May, 1920, the uterus and ovaries were normal, but a columnar carcinoma was found in a Fallopian tube, which was so distended as to resemble a hydrosalpinx.

Dr. A. H. RICHARDSON showed a Fibroma of an Ovary, with warty projections, removed from a girl of 16. Its unusual feature was its warty appearance, as it was surrounded by large papillomata with fissures 1 inch to 1½ inches deep. On microscopic examination no signs of malignancy had been found.

Mr. GORDON LEY read a paper on

The Pathology of Accidental Hæmorrhage.

The first part of his paper dealt with the literature of the subject, which he reviewed at some length. He next read pathological details of the uteri removed from three cases of accidental hæmorrhage, of the kidneys of three cases, and of the liver of two cases. He had used as controls five uteri removed ante- or post-mortem for rupture or for some condition apart from accidental hæmorrhage. He found in all uteri a leucocytic infiltration, both of the decidua and of the myometrium. This was not greater in the cases of accidental hæmorrhage than in the control uteri. He also found granules of fat in the interstitial cells of the connective tissue. These also were not more numerous in the accidental hæmorrhage cases than in the control cases. He found in the cases of accidental hæmorrhage extensive albuminous oedema of the myometrium in the outer part of the wall, both of the body and of the lower uterine segment and cervix. In the control cases there was oedema only of the stretched lower uterine segment. In the cases of accidental hæmorrhage there were focal areas of degeneration, necrosis, and hæmorrhage throughout the myometrium of the body, lower uterine segment, and cervix. The distribution of these areas of necrosis was such that they could not be attributed to the

¹ See Diseases of Children, vol. viii.

hæmorrhage. In the control cases, save for a slight vacuolar degeneration of some cells in the myometrium, there was no degeneration and necrosis, except in the stretched, cedematous, and hæmorrhagic lower uterine segment; hæmorrhage was confined entirely to the margin of ruptures and to the lower segment. He found in the liver and in the kidneys of the cases of accidental hæmorrhage parenchymatous and fatty degenerations of varying degree and extent. In one of the control cases the uterus had been suddenly stretched by an extensive intra-uterine hæmorrhage, the result of a mechanical separation of a placenta prævia, followed by the bringing down of a leg which prevented the blood from appearing externally. In this case there was neither hæmorrhage nor necrosis in the wall of the uterus. Mr. Gordon Ley concluded that the occurrence of these phenomena in cases of accidental hæmorrhage cannot arise from the uterine distension. Other conclusions formed by Mr. Gordon Ley were that accidental hæmorrhage is the result of a toxæmia of the same nature as, and probably identical with, that causing eclampsia. This toxæmia produces the focal necroses and the hæmorrhages in the myometrium; the hæmorrhage results in separation of an area of the placenta, which in turn leads to the opening up of uterine sinuses and copious intra-uterine hæmorrhage.

Discussion.

Dr. T. W. EDEN, after congratulating Mr. Gordon Ley on his paper, said that the mechanical theory of accidental hæmorrhage could not be reconciled with the focal necroses found. The investigation threw a further light on the toxæmias of pregnancy, of which pernicious vomiting and eclampsia were accepted examples, to which accidental hæmorrhage could apparently now be added. It was curious that women with accidental hæmorrhage are not as a rule more ill.

Dr. HERBERT SPENCER also congratulated Mr. Gordon Ley, but in view of the small number of cases described considered the title of the paper somewhat ambitious. Albuminuria was not a constant symptom in accidental hæmorrhage and microscopical decidual changes were known to be variable. He thought that more evidence was necessary before the toxæmia theory could be accepted.

Dr. H. BRIGGS had collected 32 cases; albuminuria was not a constant feature, and in many cases improvement followed without treatment for toxæmia.

In reply, Mr. GORDON LEY said that in a previous paper he had described an investigation from the clinical standpoint, in which 84 per cent. of cases were associated with albuminuria, and he had received accounts from colleagues in which the lowest percentage of this association was 60. He suggested that the bulk of cases without albuminuria were probably cases of lateral placenta prævia.

Remarks by the President.

The PRESIDENT referred briefly to the death of Dr. M. Handfield-Jones, and a message of sympathy was directed to be sent to Mrs. Handfield-Jones. He then said a few words on the cancer problem, with special reference to parasitic theories, with which he was not in agreement.

The meeting closed with a vote of thanks to the retiring president.

TUBERCULOSIS SOCIETY.

A GENERAL meeting of this society was held under the presidency of Dr. DE CARLE WOODCOCK on June 26th, in the City Hall, Cardiff.

Dr. JOHN BROWNLEE (Medical Research Council) gave a résumé of his recent statistical inquiries into the epidemiology of phthisis, dwelling especially on the distribution of the disease at different ages in Wales.

Diagnosis of Early Active Tubercle.

Dr. H. A. ELLIS suggested that in a considerable number of cases it was the duty of the medical man to exclude tubercle rather than to consider its possible incidence. He

admitted that this exclusion must take time and care, but in his opinion the enormous importance to the individual and to the family of the threatened persons demands time and trouble, as early recognised active tubercle almost invariably yields to treatment, with the exception of cases in young adult females. Twenty per cent. of the cases who do recover, according to Dr. Ellis, do so within six months of notification. He contended, further, that commencing activity causes autogenous absorption of the freshly-formed tuberculin, producing definite constitutional symptoms some time before lung changes could be due to active development of a tuberculous deposit. Dr. Ellis said that one of the symptoms that demand tuberculous exclusion is malaise without ascertainable cause lasting some time, and most prominent in the afternoons between 4 and 7, in contradistinction to the early morning malaise of other diseases. This malaise is more important if accompanied by loss of weight and nervous irritability and undue fatigue. Sleeplessness in the young, capricious appetite, and digestive disturbances, especially after eating uncooked cellulose, if accompanied by pain, wind, or diarrhoea, are very suspicious and always demand exclusion of T.B., likewise dislike or difficulty of assimilation of fats and fatty food. Coughs and colds, if recurrent and of increasing duration, and all forms of recurrent aphonia, laryngitis, and catarrhs, weak chests with abnormal chest signs, chronic bronchitis, pleurisy, and hæmorrhages are probably, and cold cutaneous abscesses and conjunctival phlyctenæ certainly, tuberculous. He described how he considered active tubercle should be excluded in these cases. He considered that the most important symptom when tuberculosis becomes pathological is loss of weight, and that tuberculosis rarely becomes active, and never serious, without this symptom. Tubercle can never be excluded without weighing-machines, and he advocated monthly weighing of all school children. Under normal conditions of living temperature taken in rectum always became variable or permanently elevated when tuberculosis became active; axillary temperature was useless and mouth temperature unreliable. Acceleration of the pulse was a most sensitive index; if there was no acceleration there was no active T.B. This was a negative sign, but was especially valuable after the deep inspiration practised during chest examination. Sputum was to-day insufficiently considered. More people were killed to-day by the failure to find T.B. in sputum than were saved by its discovery. It was only a negative symptom at best, as was shown in sanatoriums, since T.B. were usually present in under 60 per cent. of the patients. The character of *B. tuberculosis* was considered of great importance by Dr. Ellis. The short, straight, and unbeaded variety suggested dangerous cases with rapid extension, while the long-beaded variety suggested a slow-growing chronic case. The character of the cells was also very important. Albumin and albumose in sputum should always be tested for, as it was reliable evidence of the occurrence of T.B. in a case of bronchitis—usually a most difficult diagnosis. There must be a definite precipitate, as cloudiness does not count. No examination of sputum by itself could ever exclude tubercle. Finally, cutaneous reaction with 1 per cent. O.T. was very reliable; 95 per cent. at least of early active cases responded to this test. This was also in accord with the evidence from intracutaneous and ophthalmic reactions. If other symptoms suggested tuberculosis a 1 per cent. reaction could be considered a positive diagnosis, and where other symptoms were not in accord with the reaction active tubercle was probably present, but only as a definite menace. In conclusion, Dr. Ellis considered that active tubercle could not be excluded in cases showing malaise, nervous symptoms, afternoon fatigue, digestive disturbances, unless weight, temperature, and tuberculin 1 per cent. reaction had been tested and proved negative. Early active tuberculosis was essentially a differential diagnosis, but with these precautions it could be recognised in 95 per cent. of the cases.

The PRESIDENT then described the indications for and the means of performing artificial pneumothorax. The value of this operation in suitable cases, and particularly of massive injections of gas—Dr. Woodcock prefers oxygen—in cases of uncontrollable hæmoptysis, impressed the meeting.

Dr. PARRY MORGAN exhibited the apparatus he has introduced for performing artificial pneumothorax and explained its advantages and method of use. Interesting discussions took place on each part of the programme and the members present afterwards dined together.

On Sunday the members visited the Talgarth Sanatorium, which will be formally opened by the King and Queen to-day, July 17th. This institution, which accommodates 300 patients, stands in the centre of a large estate among the hills of Breconshire. The lay-out is that of single-storey pavilions with separate cubicles for each case. Convalescing patients supply most of the labour required for the large gardens; the original manor house of the estate is about to be converted into a post-sanatorium factory, which will at first be allocated to convalescing phthisical soldiers.

Reviews and Notices of Books.

THE MECHANISM AND GRAPHIC REGISTRATION OF THE HEART BEAT.

By THOMAS LEWIS, M.D., F.R.S., F.R.C.P., D.Sc.
London: Shaw and Sons. 1920. Pp. 452 + 20.
47s. 6d. net.

NEARLY a decade ago Dr. Thomas Lewis published a book entitled "The Mechanism of the Heart Beat," intended to give a complete account of the harvest reaped, largely during the previous decade, by a host of workers—headed by the author himself—in a field of medicine made rich by the application of exact scientific methods. Much has happened since then. A second edition, under a slightly amplified title, now before us, is a work of which its author and English medicine may be justly proud. The extent of progress may be gauged from the fact that nearly half of the 800 references in the bibliography concern papers published since the first edition. There has, however, been no important alteration in the structure of the work. The original building is there, its foundations are strengthened, gaps filled in, and worthy additions made, with the result that, after many years of exact and patient application, no branch of medicine rests on a firmer basis of revealed truth than the branch concerned with the normal and abnormal mechanism of the heart beat.

The book opens with a lucid account, illustrated with colour-photographs, of the anatomy of the special tissues concerned with the origin and propagation of the cardiac rhythm. Then follow chapters devoted to an explanation of the various means by which graphic records, "imprinted by the disease itself," may be obtained and interpreted; after which we are given a detailed consideration of the several disorders of the heart met with in clinical medicine. The plan, an admirable one, is the same in nearly every case—an account of the disorder, as it is produced experimentally in animals, is followed by a description of the identical condition occurring in patients. Both conditions are illustrated with numerous tracings. In the chapters on auricular fibrillation, however, the usual order is reversed, a description of the clinical observations preceding that of the experimental proof. In this way the author is able to present the subject as it originally presented itself—namely, as a clinical problem—and to show how the solution gradually unfolded itself and how by persistent inquiry convincing evidences were at length obtained as to the true nature of this important disorder of the human heart. Nothing could be more convincing than the weight of evidence brought to bear in support of each proposition and a comparison of the animal and human tracings laid side by side. Up till now hypothesis has not had, and could not have in such a book, any consideration. But at this point there follow three most interesting and suggestive chapters in which the author allows himself, almost apologetically, not indeed to speculate, but to disclose certain general conceptions which have guided his work. He states these views with reserve, and his vision seems justified; for after discussing and discarding Mines's circus movement as a satisfactory explanation of auricular fibrillation, a slip inserted later tells us that recent and unpublished observations strongly support this hypothesis.

Since the ultimate object of all medical research must be the prevention and alleviation of disease, it seems not impertinent to inquire what debt we, as physicians, owe to this new cardiology. No better summary could be given than that of the author, when, in a vigorously worded preface, he speaks of the immediate value of graphic records to practical medicine. He says:—

"These records have placed the entire question of irregular or disordered mechanism of the human heart upon a rational basis, so giving to the worker the confidence of knowledge; they have influenced prognosis and have rendered it more exact; they have potentially abolished the promiscuous administration of cardiac poisons, and have clearly shown the lines which therapy should follow."

This is, of course, a great debt, but it cannot be forgotten that disorders of mechanism form only a part—a large

part it is true—of heart disease, and that graphic records help us but little in that great group of sufferers whose cardiac mechanism is apparently normal but inefficient. Much, indeed, remains to be accomplished before the clinical study of heart disease as a whole can be looked upon as an exact science. It may be doubted whether we shall get much further help from animal experiments, and it is probable that a more intensive study of heart disease in all its forms in the human being will give us the knowledge of which we are in urgent need. Dr. Lewis has himself shown us in "The Soldier's Heart and the Effort Syndrome" what can be achieved by such study, and it is greatly to be hoped that in years to come he will have more to offer on the purely clinical side of this subject.

Little, perhaps, can be hoped for in the direction of immediate treatment. We can, indeed, rest an exhausted heart; we can exercise it when it is flabby; we can shield the helpless ventricle from the necessity of answering the foolish calls sent to it by a fibrillating auricle. But it seems clear that as we can never expect to replace a damaged muscle, our chief energy must be directed towards the prevention and better treatment of those affections which bequeath heart disease as their legacy. We look to the bacteriologists to find the cause and perhaps a specific cure for rheumatic fever; there is hope in the earlier and more efficient treatment of syphilis which is now possible; while there is yet much to be done in the investigation of those insidious and progressive degenerations of the cardiovascular system which spoil and shorten so many active lives. With regard to diagnosis, however, progress seems more likely. The conception of the "effort syndrome" has rendered necessary a closer investigation and more exact analysis of symptoms—the differentiation especially of those pathognomonic of heart disease, and an explanation of their mode of production. A difficult study this, for, being subjective, it will require of its workers a training in accuracy and method at least equal to that of the laboratory worker. Physical signs, again, want overhauling in the light of modern knowledge, with a clearer indication of those which are undoubted evidence of disease. Some of them have already been put to the test, and have emerged battered and dishevelled from the ordeal. We have less confidence than formerly in our estimation of the size of a heart by percussion, and systolic murmurs have been robbed of the significance they were long thought to possess. It is at least possible that many other of our traditional signs and methods have no other foundation than that "craving and veneration for hypothesis" against which the author of the book under review protests. With regard to prognosis we require more facts and less speculation. Here the general practitioner can help medicine in a very practical way by careful records of after-histories, and Dr. Lewis has elsewhere pointed out that the Ministry of Pensions is becoming possessed of a mass of valuable information under this heading which can be made good use of in the future.

The harvest, then, is not yet gathered and we are far from the gleanings. But to the workers necessary to complete our store of knowledge many should be added by the inspiration derived from reading this book.

PASTEUR: THE HISTORY OF A MIND.

By EMILE DUCLAUX. Translated by E. F. SMITH and F. HEDGES. London and Philadelphia: W. B. Saunders Company. 1920. Pp. 363. 21s.

Duclaux was born in 1840 and first came into contact with Pasteur, 18 years his senior, at the Normal School in Paris in 1859. First as pupil, later as assistant, he stayed with Pasteur for six years, then went off to professorships of chemistry and physics and did not finally settle down in Paris till 1878. In 1888 he became director of the newly founded Institut Pasteur, started the *Annales*, and was the glowing apostle of his master and of his own ideals until his death in 1904. This book was written soon after Pasteur's death in 1895, but seems to have attracted very little notice. Professor Erwin Smith came across a secondhand copy and was so impressed that he thought an English version was

worth while. It may be so, though it is likely that there will be some who differ from him. The book is, indeed, a wonderfully sympathetic account of a pilgrimage which will always be one of the landmarks of biological progress, its troubles and its retreats no less than its successes. But one wonders a little whether the Pasteur cult is not at times liable to be overdone: the study of the past is useful only in so far as it helps us to get forward to-morrow, and the position with which Pasteur had to deal is, through his own immense progress, part of a past so remote that it seems to-day unreal and disconnected from the current world. A good many, in short, will probably find the book rather dull. In the delightful American fashion, there are several portraits of Pasteur and two of Duclaux, which make one wish that there was more about the latter than the translators' 30 pages of introduction, which are the best in the volume.

THE BREAST: ITS ANOMALIES, ITS DISEASES, AND THEIR TREATMENT.

By JOHN B. DEEVER, M.D., LL.D., Sc.D., and JOSEPH MCFARLAND, M.D., Sc.D. Assisted by J. LEON HERMAN, B.S., M.D. London: William Heinemann (Medical Books). 1920. With 8 coloured plates and 227 illustrations in the text. Pp. 724. £2 net.

Dr. Deever and his colleagues have managed in 700 odd pages to present, lucidly and exhaustively, all that is claimed by the title, and the completeness of the bibliography gives their book a value possessed by no other work on this subject in the English language. The authors have read widely and pay just tribute to their sources of information. If there is a fault it lies in the diffidence of their claims, and the avoidance of dogmatism, which we sometimes find welcome in a high authority.

The book opens with an untrammelled account of the development, histology, anatomy, and physiology of the human breast, followed by an instructive description of the congenital and acquired anomalies. The next section deals with the infections, and contains an excellent account of tuberculous breast lesions. Thoughtful consideration is given to the cystic conditions of the breast. Dr. Deever is not one who sees in every mastitic breast a precancerous condition. He prefers, after reviewing the inflammatory and neoplastic hypotheses, to see chronic interstitial mastitis as a process of abnormal involution evidenced microscopically by both cystic and proliferative changes. Although admitting its frequent association with carcinoma, he denies the evidence and conclusions of Mr. Sampson Handley, who frankly states mastitis to be the almost universal precursor of carcinoma. Deever is in agreement with opinion in this country when he states that the question of the malignancy of a breast tumour is seldom in doubt, and that it is unusual for the frozen section to reveal that which the gross section could not demonstrate.

After a brief but engrossing presentation of the general pathology of tumours we get a detailed clinical and pathological description of the benign tumours of the breast. Seventy pages are given to sarcoma, and the remaining 200 to the question of cancer. The evolution of the modern conception of cancer is traced, and the hypotheses of each succeeding generation are considered. A résumé is given of the more recent work upon the possibility of the sero-diagnosis of cancer. The authors discuss the meiotagmin reaction depending upon the laws of surface-tension; v. Dungern's complement-fixation test; the antitrypsin reaction of Brieger and Triebig; the various tests depending for their demonstration upon hæmolytic phenomena; and the application of Abderhalden's colour-reaction for the detection of alleged anticancerous ferments in the blood. In the latter connexion, it should be remarked that Leitch's destructive criticism of Abderhalden's claims was not then in the authors' hands. The authors refuse to lend their authority to a classification of breast cancer upon microscopical evidence alone. Their method is clinical, and they are content to recognise six varieties of cancer of the breast. The signs of breast cancer are given in detail, and their significance considered. Some

pathologists would prefer to differentiate "dimpling of the skin," which is a mechanical phenomenon, from true *peau d'orange*, which has been shown by Leitch to be an actual cancerous invasion of the skin.

In a later chapter Dr. Deever discusses the criteria which determine operability, and here the sane judgment and moderate claims mark the practised clinician. The operative treatment he regards as having originated with Charles Moore, of Middlesex Hospital, in 1867, to undergo, at the hands of Lister, Watson Cheyne, Volkmann, and Halsted, the developments which have given us our modern "en bloc" amputation. We miss a mention of Mitchell Banks's work in this connexion. Full justice is done to Handley's doctrine of permeation and its necessary corollary of perilymphatic fibrosis, and the authors state that the removals of fascia as advocated by Handley are imperative in the modern surgery of breast cancer. We gather, however, that, like Halsted, they favour the wide removal of skins, and view with suspicion the narrow skin removals to which the surgeon is tempted who follows too wholeheartedly in Handley's steps.

The book closes with a chapter from the pen of Dr. Pfähler, from which, in a footnote, Dr. Deever appears to disassociate himself. A full account is given of the resources of the radiologist as applied to breast cancer, and if the trend appears to some to be too optimistic an acquaintance with the work which Dr. R. Knox and others are doing in London might restore their faith. We congratulate the authors upon their achievement, and most heartily recommend the book to all. For the student it is a library of knowledge, for the tutor an easy work of reference, and for the consultant a guide both for prognosis and operative treatment.

LE SYMPATHIQUE ET LES SYSTÈMES ASSOCIÉS.

Anatomie Clinique, Sémiologie, et Pathologie Générale du Système Neuro-glandulaire de la Vie Organique. By A. C. GUILLAUME. Preface by Prof. PIERRE MARIE. Paris: Masson et Cie. 1920. Pp. 160. Fr. 6.50.

Dr. Guillaume has written a particularly useful little compendium of knowledge on the sympathetic nervous system—the Land of Promise, according to Professor Pierre Marie. He rejects the terms "involuntary" (Gaskell), "autonomic" (Langley), and "vegetative" (Higier), preferring "organic neuro-glandular system" to any—since glandular and sympathetic systems are so closely interwoven as to be physiologically and pathologically inseparable. He uses the expression "parasympathetic" for the pelvic and cranial sections of the system, thus himself scarcely escaping the redundant nomenclature to which most writers on the subject seem committed. A simple, non-committal, not too detailed terminology is requisite if confusion is to be avoided. A morphological description of the system is followed by a consideration of its central representation. According to the author there is evidence that in the immediate vicinity of the motor area of the cortex are sympathetic "centres," and the dubious contention is advanced that the frontal lobes are responsible for somatic emaciation and the occipital for adiposity. The physiology of the system, sympathetic and parasympathetic, is next discussed in considerable minuteness, and various syndromes connected with irritative or destructive lesions of its different parts are sketched. Its pharmacology, too, receives due attention. Some criticism is directed to Eppinger and Hess's conceptions of sympathicotonus and vagotonus, and the latter term is replaced by neurotonus, which seems even more unsatisfactory.

The diagrams illustrating the book are unusually clear and uncomplicated, and are worth individual study. In Fig. 4 the position of the important intermedio-lateral tract does not correspond precisely to what we have learned from the authoritative work of Bruce on the subject. The arrow in Fig. 5 indicating the "Masse de Stilling-Clarke" points erroneously to the midline of the cord. In Fig. 6 "Bogiel" is an obvious slip for "Dogiel." We miss any diagrammatic representation of the central connexions of the cervical sympathetic through the formatio reticularis of the medulla.

THE NEW CHILDREN.

Talks with Dr. Maria Montessori. By SHEILA RADICE. London: Hodder and Stoughton. 1920. Pp. 170. 4s.

THIS is the work not of a critic, but of an enthusiastic admirer. And the Montessori methods, in theory as well as in practice, are in need of criticism, else why is there so much hostility among teachers to Montessori teaching at the present day? By criticism we mean a fair, impartial examination of the theory and of the practice by those who are competent, both in their expert scientific knowledge and in their sound understanding of child life, to analyse and to estimate values. We believe that the Montessori system of teaching will emerge vindicated and triumphant from such criticism, which, we repeat, is not to be found in this little volume. "The New Children" makes good reading for the half-initiated; it is fluent, graphic, and versatile. It touches lightly yet significantly upon many matters—for example, psycho-analysis—which are Greek to those ignorant of the subject and platitudes to the expert, while relevant to the whole problem. The author has evidently grasped the scientific truth that permeates and inspires the Montessori doctrine and has appreciated, though she may not have revealed it clearly, the relativity of the Bergsonian philosophy. And the reading public to which, on the whole, this book is likely to appeal, need enlightenment in these two directions in order to appreciate the full significance of their application to Montessori teaching. The chapters on music, suggestion, and training for citizenship attempt to justify certain phases of the Montessori system which have frequently been exposed to prejudicial criticism from those who have no acquaintance with work in the actual schools, and who forget that application of the methods by other persons in other lands may be influenced and altered by local and by personal factors. Mrs. Radice's book is an endeavour to report Dr. Montessori's own interpretation of her methods of teaching. She does not mention, however, the tendency in this country to liberate the principles governing the system from association with one personality only, and to embody them in what is now known as Auto-education.

JOURNALS.

American Journal of Ophthalmology. January-May, 1920.—We select a few articles for comment. January: H. V. Würdemann. Syphilitic Neuroretinitis. There is a coloured plate showing six examples of this condition. Out of 460 syphilitics under treatment at Camp Lewis 14 cases were found, in only 4 of which had the patient observed any diminution of vision. The severity of the cases varied very much. In no case was there a swelling comparable to cases of choked disc. The course of low grades of optic neuritis, from whatever cause, varies from a few weeks to several months, and may be followed by complete resolution, or in severe cases may leave a certain amount of greyish atrophy. The treatment is that of its cause.—A. E. Ewing. Test Objects for the Illiterate. A useful compilation of tests from various sources.—E. E. Maddox (Bournemouth). Venesection as a Preventive for Expulsive Hemorrhage. A case of cataract in a patient of 78 suffering from myxœdema, malaria, and gout. Operation on the first eye was spoiled by an expulsive hemorrhage. Various measures were taken to safeguard the operation on the second eye, the most important one being a free venesection immediately before the operation. The result was entirely successful.

February: Arnold Knapp. Hypotomy after Trephining. Four cases are related. The 2 mm. trephine was used in the first three and a 1½ mm. trephine in the fourth. The cases were watched for periods of from four to six years. Out of the six eyes operated on, in three there was no loss of sight or ocular change. In one the eye was lost from phthisis bulbi, and in the remaining two there was cataract. The author deems it advisable to use the smaller size trephine.—W. G. Dickinson. Ocular Manifestations in Cerebellar Syphilis. By far the larger number of cases reported have been predominated by ophthalmoplegias of the external muscles and pupillary dyscrasias. Optic nerve-changes vary from mild degrees of papillitis to well-advanced choked disc.

March: J. Van der Hoeve. Eye Lesions Produced by Light Rich in Ultra-violet Rays. The author believes that a principal cause of the origin of senile cataract is the influence of light rich in ultra-violet rays, such as daylight, which causes the opacity by interfering with the nutrition of the lens, the injury being due to damage to the ciliary processes by rays dispersed against their epithelium. In case

these rays, instead of being dispersed, pass through the lens they are liable to cause senile macular degeneration. According to this theory these two conditions are mutually exclusive.—L. Weekers. Alterations in Twilight Vision in Occupational Nystagmus. The night blindness so commonly seen during the late war as a result of fatigue chiefly occurred in infantrymen who were subject to the most trying conditions during night marches. In coal miners suffering from nystagmus it is also sometimes found, and here the same two conditions account for it, fatigue and bad lighting conditions. It is an effect of fatigue in the mechanism for dark adaptation.

April: Burton Chance. Symmetric Macular Degeneration in a Brother and Sister. A coloured plate shows a good example of the condition described by Rayner Batten, Darier, and others.

May: H. V. Würdemann. The Fundus of the Eye after Death. Two coloured plates are given showing the fundus oculi respectively 30 minutes and 2 hours after death. The changes are not unlike what are found in cases of complete obstruction of the central artery of the retina during life.

The *Journal of Industrial Hygiene*. London: Macmillan and Co., Ltd. 3s. 6d. monthly, or 21s. yearly.—The subject of industrial diseases as exemplified by industrial poisons has been dealt with in several recent articles in this journal. An interesting report by Professor S. Delépine on a fatal case of arseniuretted hydrogen was published last November. The interest lies in the few recorded instances of such cases. The symptoms—jaundice with sickness, diarrhoea, and hæmoglobinuria—were typical, and arsenic was found in the liver; while the organs, particularly the kidneys and liver (the conditions of which are illustrated), showed marked degenerative changes. The rubber industry is the subject of two references. In the March issue Dr. T. M. Legge discusses the occurrence of cases (one fatal) of purpura hæmorrhagica caused by continued exposure to fumes of benzene (crystallisable benzol). The symptoms and pathological findings were those of aplastic anemia, as exhibited occasionally by workers manipulating T.N.T. Improved ventilation, together with careful medical supervision, has put a stop to the occurrence of further cases. Messrs. N. A. Sheppard and S. Krall describe in the May number a rash due to hexamethylene-tetramine, used as an organic accelerator in vulcanisation; and, after careful consideration, propose as a remedy the application to exposed parts of a saturated solution of sodium bicarbonate. The rash starts as an erythema, quickly followed by vesicles which rupture and exude serum; it is most prevalent in hot weather, and a direct relation appears to exist between sweating and its occurrence. Exposed parts of the face, neck, and forearms are particularly affected. The remedy suggested has given valuable results.

Dr. W. Salant reviews in the June issue the pharmacology of the heavy metals, and describes special laboratory investigations into the toxicity of zinc and tin. Administration of these metals to animals was followed by symptoms of poisoning, but relatively large doses were required unless the metal was introduced directly into the circulation. The author concludes that while certain heavy metals, such as lead, are degenerative poisons, they are apparently well borne when taken with food; but he gives a warning that if the digestive mucous membrane be out of order absorption may occur and serious damage follow.

Dr. T. M. Legge, in the April number, deals with 20 years' experience of notified industrial diseases—i.e., anthrax and poisoning by lead, arsenic, mercury, and phosphorus. This résumé is one of great value; from it we see how, when once the means for preventing a disease are understood, that disease may be reduced. Lead-poisoning may be instanced; its cause is *par excellence* dust inhalation; there were 1058 cases in 1900 and only 144 in 1918. Toxic jaundice, which only became notifiable in the last three years under review, is the only other disease similarly controlled; there were 206 cases among munition workers in 1916, and only 34 in 1918. Important as these results are, and skilfully as they are presented, we are struck with the comparatively small portion of the field of industrial troubles covered by notifiable diseases; and feel that the health of the industrial worker cannot be left to wait for improvement from procedure on these lines. Investigation into only 265 cases of all kinds in 1918 among some eight million workers is hardly a convincing effort on the part of those responsible for factory supervision.

A further article on diseases for which workmen's compensation is payable, by the same author, in the May number gives support to this view. Here are reported as occurring among the miners, who number about one million, some 5500 cases of nystagmus, beat-hand, beat-knee, and the like, which are not notified or medically investigated. Dr. Legge sets out in clear and easily understandable terms the principles underlying, and the somewhat complicated procedure of, the Compensation Acts, and also describes action taken in South Africa and New Zealand with regard to fibroid phthisis. This article is one of great value to every practitioner working in an industrial area.

THE BRITISH MEDICAL ASSOCIATION.

EIGHTY-EIGHTH ANNUAL MEETING AT
CAMBRIDGE.

SECTION OF SURGERY.

WEDNESDAY, JUNE 30TH.

Gastric Ulcer.

THE discussion on Gastric Ulcer on June 30th was opened by Sir BERKELEY MOYNIHAN. The burden of his message was a strong plea for the practice of partial gastrectomy as the operation of choice in the treatment of gastric ulcer, and he supported his view with impressive statistics of his results. He claimed that the technique of operative treatment was now simple and perfect, and that good results had been rendered almost certain. Surgery had, indeed, now risen beyond mere technique. It should be the surgeon's aim to discover if possible the primary source of the condition which produced the ulcer and to rectify this. Often the source was to be found in the abdomen; in other cases it lay in the teeth or the air sinuses, and it was therefore important to make an exhaustive examination of the buccal cavity and its surroundings. Operative treatment was a confession that medical treatment had failed, and often such medical treatment as was practised, especially in hospital out-patient departments, was from the beginning doomed to fail. Close supervision for months was necessary if so large an area as a gastric ulcer was to heal, and it was always necessary to treat the poor condition of the patient by rest in bed, with alkalies by the mouth, and sometimes by the transfusion of blood. Starvation treatment he believed to be radically wrong, and preferred to give as much fluid by the mouth as could be taken.

Gastro-enterostomy, first done by Wolfier on Sept. 27th, 1889, was still the favourite operation, and no operation in surgery was followed by swifter or more striking results. Surgical enthusiasms were very contagious things, and soon the operation came to be practised in cases in which there was no obstructive element; failures resulted, and for these there were several reasons, such as that the anterior operation was done instead of the posterior, that the opening was too small, that the gut had been rotated, and various other technical faults. Also there had been bad choice of cases. Sir Berkeley Moynihan emphasised the fact that gastric ulcer was a relatively rare condition. Operations had been done on the strength of a symptomatic diagnosis, and he had in many instances undone a gastro-enterostomy where the real source of the trouble was found to be an appendix abscess, an empyema of the antrum, cholelithiasis, tabes, or even the vomiting of pregnancy.

Cases of gastro-enterostomy could be roughly divided into three categories: 1. Those in which results were excellent. In these the ulcer was near the pylorus and perhaps had healed, so that there was a partial obstruction, or spasm of the pyloric end of the stomach. 2. Those in which results were poor; very many of these were attended by a non-healing ulcer of the jejunum after the operation. 3. Those in which a carcinoma eventually developed, presumably arising in the base of an originally non-malignant ulcer. No agreement was yet possible as to whether or no carcinoma really did develop in the base of a simple ulcer, but the clinical histories of cases, pathological investigations, and the histological examination of excised ulcers all tended to show that this did actually occur. Gastro-enterostomy had now, as an operation, ceased to satisfy modern expectations. Nevertheless, many surgeons still relied upon it, and he himself parted with it with reluctance. It had served him well. He had had no death in the last 400 cases in which he had practised it, and he felt towards it no menace in his heart.

Sir Berkeley Moynihan mentioned briefly the various modifications of the operation that were practised, and drew attention to the value of occasionally performing a jejuno-jejunostomy in addition to gastro-enterostomy. It was noticeable that gastric and duodenal ulcers affected quite different types of stomach. The gastric ulcer was found in atonic, lazy stomachs; the duodenal was associated with the strong stomach, and often occurred in young men and athletes. Gastric ulcer was at once a rare and a serious disease, and he had found a mortality of 17½ per cent. occurring in the three years following operation, which was in itself a condemnation of gastro-enterostomy. He had found, on the other hand, that a partial gastrectomy was actually a safer

operation, with a mortality of only 2½ per cent. Patients who had undergone it ceased absolutely to be patients. They never came back with recurrent symptoms, or, indeed, with anything at all, except a heart full of gratitude. Sir Berkeley Moynihan laid down with great emphasis that it was the little things that counted in the achieving of success. Care was the keynote—care in the preliminary examination, in preparing for the operation, and during the operation. Speed was also important, but could only be attained by long practice; it should be the child of experience and not the parent of disaster.

Sir Berkeley Moynihan then gave some striking statistics to show the relative mortality of the allied conditions—gastric ulcer, 2.9 per cent.; duodenal ulcer, 0.5 per cent.; jejunal ulcer, 7 per cent. This very serious complication with jejunal ulcer was a strong argument in favour of partial gastrectomy as against gastro-enterostomy. He did not, however, claim that finality had been reached in this operation. He was not yet satisfied, for happiness depended upon the existence of unsatisfied, but still attainable, desires. He concluded with a technical point—that it is unnecessary to use silk or thread in these operations. It was perfectly safe, and far better, to use nothing but the finest catgut.

Dr. CHARLES H. MAYO (Rochester, Minn.), who next addressed the meeting, received a great ovation; he modestly disclaimed this on his own account, but accepted it as the representative of the medical profession of the United States. Dr. Mayo did not attempt to refute any of Sir Berkeley Moynihan's contentions, but contributed a learned and weighty review of the subject under discussion. He gave statistics to show that gastric ulcer was a relatively rare disease and that the ulcer was nearly always single. In discussing the ætiology of gastric ulcer he put forward the theory that the ulcer is produced by an association of local chemical effects, with a direct interference with circulation by infarction emboli of bacteria. Characteristic bacteria could be grown from an excised ulcer, and an injection of these into animals produced a high percentage of similar ulcers. The chronicity of the disease was to be explained by the chemistry of the bacterial products. Medical treatment, the coördination of which was chiefly due to Dr. Sippey of Chicago, was directed towards the control of acidity in the stomach by dilution and neutralisation, but such treatment produced only temporary results and could not always be obtained. During the long periods of treatment which are necessary under urgent conditions, such as perforations, may arise which demand surgical treatment, and not a few cases develop cancer, resulting in death. In the past surgery had sometimes earned discredit through the performance of gastro-enterostomy on the basis of a mistaken diagnosis, and in the Mayo Clinic a few hundred such operations had had to be undone.

Dr. Mayo laid stress in making a diagnosis on the clinical and dietetic history. He distinguished between qualitative and quantitative food-dyspepsia, the former being usually not due to an ulcer. Haemorrhage was not a symptom of importance in most cases. He placed great reliance on X rays in diagnosis, a correct diagnosis being arrived at by this means in 95 per cent. of cases; it was particularly valuable in helping to distinguish between gastric and duodenal ulcer. He agreed with Mr. Herbert Paterson that after gastro-enterostomy had been performed the alkaline secretions of the duodenum tended to reduce the acidity in the stomach, and that this change in local environment encouraged healing of the ulcer. At the Mayo Clinic the mortality after operation for gastric ulcer was nearly double that for duodenal ulcer. Various statistics were given of the position, age- and sex-incidence of gastric ulcer. Investigations that had been carried out led Dr. Mayo to reiterate that gastric ulcer is potentially malignant.

In discussing the various operations that could be performed the anterior route of approach and anterior anastomosis were favoured. Gastro-jejunal ulcer was believed to be due to the use of permanent suture material and to the presence of chronic foci of streptococcal infection. Dr. Mayo stated, in conclusion, that surgical treatment was the best recognition of the value of medical treatment by permanently overcoming obstruction and by lowering acidity with the patient's own alkalies.

Mr. HERBERT PATERSON (London) made a strong plea for clear-thinking concerning the indications for operation and its results. In this connexion he accused Sir Berkeley Moynihan of an admirable inconsistency between his scepticism as to there being any physiological factor in the results of gastro-enterostomy and some of his other statements. He was never afraid to

change his attitude, but the change was made in so graceful and facile a manner that it was hardly noticed even by his friends. Mr. Paterson believed firmly himself in the reduction of acidity after operation by the entry into the stomach of alkaline duodenal juices. After undoing a gastro-enterostomy there was a return to the previous degree of acidity, whereas a decreased acidity does not accompany the operation if an entero-anastomosis be done at the same time. Concerning the development of cancer in a gastric ulcer, he considered that there was no clinical evidence for it, and that the pathological evidence was unconvincing.

Mr. A. H. BURGESS (Manchester) believed that too much was expected of gastro-enterostomy. Its object was twofold—to get rid of the ulcer and to get rid of hyperacidity. The best results were obtained from a combination of excision and gastro-enterostomy. But excision was often very difficult, and, consequently, the best routine operation was a partial gastrectomy. This was not to be done when the ulcer was very high in the lesser curvature and when it was too extensive. In these cases gastro-enterostomy with jejunostomy was the best treatment. The physiological effect of the operation he considered to be proved. He discussed whether the edges of the opening in the transverse mesocolon should be attached along the line of anastomosis or at a distance, and favoured the second alternative, having seen a constricting scar formed within 12 days of the operation. He emphasised the importance of giving alkalis in after-treatment.

Mr. CHARLES RYALL (London) regarded a gastric ulcer as a simple inflammatory process with a predisposing cause in hyperacidity and an undetermined exciting cause. Ulcers do heal, and a gastro-enterostomy had been proved to provide a physiological rest. No fixed operation should be used, and excision should not be done in every case. He believed that an exaggerated importance had been given to the development of carcinoma in an ulcer.

Professor J. M. T. FINNEY (Baltimore) stated that in practice he had found it hard to diagnose the presence of a gastric ulcer even with the abdomen open before him. Sometimes there was no response to treatment, and he had failed often enough to be sceptical of any rule. Speaking on behalf of "the common barnyard surgeon" he considered that every case should be treated on its merits. He advocated pyloroplasty owing to the opportunities it gave for making a thorough examination of the stomach. The group for which resection was suitable was ever widening. He had had no mortality yet, but it was bound to come, and he was therefore sorry for every patient upon whom he operated.

Mr. W. BILLINGTON (Birmingham) was still seeking for a satisfactory explanation of the symptoms. He discussed the way in which the site of the ulcer influenced the success of the operation, and believed that excision alone was a bad operation. He was shaken in his belief in the physiological effect of gastro-enterostomy, as he had obtained better results by combining it with a jejuno-jejunostomy, so that alkaline fluids were prevented from reaching the stomach. Every ulcer in the body of the stomach he treated as an hour-glass stomach by making a double opening, and had obtained good results in 50 cases.

Mr. R. P. ROWLANDS (London) dwelt on the uncertainties of diagnosis, and on the necessity for examining the whole abdomen at operations. Gastro-enterostomy was like magic and should be used with caution. He insisted that it was perilous to advocate the extended use of so difficult an operation as partial gastrectomy by the general surgeon.

After a few remarks from Sir GEORGE MAKINS,

Sir BERKELEY MOYNIHAN made a short reply to his critics. He defended his scepticism concerning the hydrochloric-acid findings, which in any case were below normal in a large number of *proved* gastric ulcers, and he gloried in his inconsistency. The operative mortality from gastro-enterostomy, which was often followed by a fatal carcinoma, was equal to that

following gastrectomy, which cured all patients for ever. Mr. Paterson, he said, had long been a devout worshipper at the shrine of the goddess Hyperchlorhydria, and he described him in the following lines from Shakespeare's sonnets:—

O, know, sweet love, I always write of you,
And you and love are still my argument;
So all my best is dressing old words new,
Spending again what is already spent.

Mr. FRANK KIDD (London) opened the second discussion on

The Treatment of Calculi in the Pelvic Part of the Ureter. Stones in the ureter, he said, were usually single. There were several stages in the effects following the presence of a stone. Fibrosis gradually developed in the tissues of the pelvic wall surrounding the stone; then the ureter above the stone became dilated, bacterial infection arrived by the blood-stream or lymphatics, and a pyonephrosis resulted. Sometimes, however, the calculus was silent for years, and then gave rise to symptoms resembling renal colic. An accurate diagnosis was absolutely essential, and for this X rays should be used. There were fallacies in the shadows produced by various other opaque bodies in the pelvis, and an opaque ureteric bougie or the injection of 20 per cent. colloidal silver must always be used to confirm the X ray diagnosis before any operation was done.

He considered that in treatment no operation was necessary in the majority of cases. A chance should always be given for the natural passage of the stone, as there was no time-limit for this; the ureter was rarely completely blocked, and the kidney was often able to recover after prolonged partial blockage. An operation, however, should be done in cases that were infected, when the stone was bilateral, where there was calculus anuria, or when there was long-established and fixed pain. In many cases an operating cystoscope could be used. A natural passage of the stone could be encouraged by the injection of parolein round the stone, or incision and dilatation of the mouth of the ureter could be practised, followed by extraction of the stone with forceps. In operating an inguinal or mid-line incision could be used. He himself usually employed the inguinal route, reserving the middle-line incision for bilateral stones or for cases of unusual difficulty. Sometimes stones moved in a dilated ureter, and an X ray photograph should always be taken just before the operation. For purposes of diagnosis it was essential to detect blood microscopically in the urine. Mr. Kidd's main contention was for conservative methods in treatment.

Mr. SWIFT JOLY (London) disagreed with Mr. Kidd on his chief points. He preferred the median incision in most cases, and considered that operation was usually the most satisfactory method of treatment. This was determined in many cases by the size of the stone, since only those that were smaller than orange-pips could be readily dislodged by injections of the ureter and similar methods. It was also helpful to take X ray photographs after successive attacks of colic, and so determine whether the stone showed any tendency towards moving or not.

Mr. GREY TURNER (Newcastle-on-Tyne) was against the performance of an operation if the stone was small. An examination of the patient per vaginam or per rectum was often helpful, though sometimes omitted.

Mr. ROWLANDS had removed a number of ureteral calculi which, though large, were not opaque to X rays. He regarded cystoscopy, combined with an indigo-carmin injection, as a useful method of confirming a diagnosis of obstructed ureter. He was opposed to exposing the kidney to the risk of destruction for so long a time as was advocated by Mr. Kidd.

Sir HAMILTON BALLANCE (Norwich) and Dr. MAYO also contributed some remarks to the discussion.

THURSDAY, JULY 1ST.

Carcinoma of the Rectum.

The discussion on July 1st on the Treatment of Carcinoma of the Rectum was opened by Mr. ERNEST MILES (London), who appeared as the advocate of his abdomino-perineal method of resection of the lower bowel. He contended that all operations must be founded on the pathological findings, and that removal of any growth must include the whole of the tissues affected by the disease. Carcinoma of the rectum spread by

three methods—by direct extension, by the venous, and by the lymphatic channels. Of these the extra-mural lymphatic channels were by far the most important, and he illustrated by diagrams, which were based on his own investigations, the various routes, disposed in three zones, by which cancer cells might reach the lymphatic glands situated at the bifurcation of the common iliac artery. The most vulnerable tissues were the perianal fat and the levator ani muscle, the retro-rectal glands, and the parietal attachment of the pelvic mesocolon.

Mr. Miles then reviewed the various methods of perineal resection of the rectum, and dismissed them all as inadequate. He traced the various stages by which the operation from below had been extended, but pointed out that the most radical of these left the pelvic mesocolon behind, which was still out of reach. He condemned as unsound those operations which attempted to preserve a continent anus. He arrived thus at the description of his abdomino-perineal operation, which was planned with a view to the removal of the whole of the pelvic mesocolon, "the axilla of the rectum." He admitted that his operation mortality had been at first as high as 43 per cent., but it had now fallen to 18 per cent., whereas, if the pelvic mesocolon were not removed, 100 per cent. died from recurrence of the disease. He contended that the operation was particularly suitable for early cases, but should not be done in old patients, who could not stand a severe operation. In these a colostomy or a perineal excision could be performed as a palliative.

The subsequent discussion resolved itself into a contest between those who agreed with Mr. Miles and those who were in favour of operating from below in most cases.

Mr. GREY TURNER, while agreeing with Mr. Miles as to the mode of spread of the disease, believed that as an early diagnosis came to be more frequently made, so a local removal would be more often adequate. He was unable to understand how Mr. Miles came to have 100 per cent. of failures if the pelvic mesocolon were not removed, as he was himself able to record a number of cases of apparent cure after a local operation. Nevertheless, surgical progress must not be clogged by considering operative mortality in a disease which resulted in 100 per cent. mortality if left alone. For growths high up in the rectum perineal or sacral resection would not be enough, and he would not hesitate in that case to remove the pelvic colon by the abdominal route. In considering the range of operability he was not deterred by local fixation of the growth unless the bladder were involved. Often a preliminary colostomy rendered a growth operable when it had seemed at first inoperable.

Mr. P. LOCKHART-MUMMERY (London) said he had been one of the first surgeons in this country to practise the abdomino-perineal operation. He was still performing it in special cases, but had abandoned it as a routine and was now trying to develop a technique which, while giving a free removal of the growth, would reduce the operation mortality to a reasonable level. During the present year he had had no deaths in 24 cases operated upon. The operation was usually done in two stages, the first of which was a colostomy through the left rectus muscle. The second operation for removal of the rectum was done under spinal anaesthesia a week later. The anus is first closed and the rectum then freed by dissection from in front and from the perineum upwards. The bowel is divided with the cautery between clamps and the end is invaginated. The wound is closed without drainage. The late results appeared to be quite as good as were obtained after the abdomino-perineal operation, while the immediate mortality was reduced almost to nil.

Mr. BURGESS, while convinced on logical and theoretical grounds that Mr. Miles was right, did not follow him out in practice, being deterred by the high operation mortality. He agreed that if the abdomino-perineal operation were used at all, it must not be reserved only for bad cases. The earlier the case the more extensive was the operation that was indicated.

Mr. RYALL was strongly of the opinion that no routine operation should be performed, but that every case should be considered strictly on its merits. Mr. Miles's operation he believed to be the only sound and scientific one, and he was confident that time would reduce the

mortality to a low figure. He considered that an early colostomy to remove sepsis and inflammation was an exceedingly important part of the treatment.

Dr. H. H. BROWN (Ipswich) recorded several cases that were alive and well after a relatively restricted operation, and recounted an attempt to conserve the sphincteric action of the anus.

Sir GORDON WATSON (London) believed that the treatment of this disease was still far from stabilised. Even Sir Berkeley Moynihan had told him that he had changed his mind on this subject more often than on any other surgical problem. He himself had been convinced by Mr. Miles's arguments and technique in 1909, but his own results with the abdomino-perineal operation had been very discouraging. By a process of statistical reasoning he had arrived at the conclusion that the final results of Mr. Lockhart-Mummery's operation were 1 per cent. better than those of Mr. Miles, and he consequently was now reserving the abdomino-perineal operation for cases of cancer at the recto-sigmoidal junction or above it.

Dr. MAYO stated that he had no use for any routine operation. At the Mayo Clinic all the methods were employed. He pointed out that the enlarged glands in the mesocolon were often inflammatory and not carcinomatous; a rapid diagnosis with frozen sections could be made during the course of the operation and the procedure then modified accordingly. Dr. Mayo then diverged on to an interesting general consideration of the biological problems of cancer growth.

Mr. JOCELYN SWAN (London) was a convinced adherent of Mr. Miles's method. He himself had so far been lucky enough to have had no operative mortality in 11 cases.

Mr. D. P. D. WILKIE (Edinburgh) put in a strong plea for Mr. Grey Turner's view of the great importance of retaining sphincteric control if possible. He admitted that it was difficult to criticise Mr. Miles's ideal operation, but considered that its high mortality prohibited its general use. The chief dangers of the operation he believed to be shock and sepsis, particularly septic pneumonia. He therefore suggested that the patient be immunised before operation with vaccines or be protected by inducing a leucocytic reaction.

After a few remarks from Sir HAMILTON BALLANCE and Mr. HAMILTON DRUMMOND (Newcastle-on-Tyne), the two speakers who had opened the discussion made short replies. Mr. GREY TURNER reiterated his conviction that the local removal was far more important than removal of possible distant infection. Mr. MILES admitted the absolute necessity for local removal, but was convinced that the region of upward spread was of equal importance. He was in favour of performing a preliminary caecostomy to drain the bowel, and considered that spinal anaesthesia with gas and oxygen was the best form of anaesthetic.

The Diagnosis of Glaucoma.

The second subject, the Diagnosis of Glaucoma, was introduced by Lieutenant-Colonel R. H. ELLIOT (London). He stated that the history of the subject could be divided into three stages, marked by the names of Hippocrates, Helmholtz, who introduced the ophthalmoscope, and Lefrange, who in 1906 introduced the operation of sclerectomy. The condition can be arrested if a diagnosis be made early and if the treatment be rational. The methods of diagnosis which Colonel Elliot described were: (1) Observation of the pulsation of the retinal vessels; (2) the measurement of intraocular pressure by the tonometer; and (3) the accurate investigation of limitation of the field of vision by perimetry. He referred also to examination of the light sense and to corneal measurements.

There was a short discussion, in which Mr. WALLACE HENRY (Leicester) and Mr. G. E. WHERRY (Cambridge) took part.

FRIDAY, JULY 2ND.

Nerve Suture and its Results.

The discussion on Friday, July 2nd, concerning nerve suture and its results turned chiefly on the value of nerve grafts and implantation operations; the speakers

were in substantial agreement as to the technique and results of the ordinary suture operation.

The opening speech was delivered by Sir WILLIAM THORBURN, who dwelt rather on the general principles. Beginning with the accepted fact that repair depends on the downgrowth of axons from the proximal end, he pointed out that a good anatomical result depends upon the downgrowth of a sufficient number of axons into a corresponding number of sheaths. On the other hand, a good physiological result means that the right axons must have encountered those conducting sheaths which will have taken them to the right kind of end-organs—that is to say, motor nerve fibres to motor end-organs and sensory fibres to sensory end-organs. Usually, however, there was some nerve “shunting”—that is, the downgrowth of nerve fibres to end-organs other than those with which they were originally connected. Sometimes this was done intentionally, as when the proximal part of the hypoglossal nerve was sutured to the distal part of the facial. More often this took place on a histological scale, motor fibres growing down to sensory end-organs and sensory to motor. This was partly due to the difficulty of accurate coaptation of the ends, but also to the fact that the fibres of a nerve were twisted like the strands of a rope, so that any given fibre was constantly altering its relative position in the nerve. This fact rendered futile some operations, such as that of making nerve flaps, which were practised up to 1915 but had now been discarded. It was on the face of it improbable that a nerve graft should give a good physiological result, however perfect the surgical technique. A third point of view from which results had to be considered was the economic. Often the economic result was better than either the anatomical or the physiological. He had seen, for instance, a restoration of the function of the ulnar nerve which appeared economically to be complete, though there remained an anæsthesia of the area supplied by the ulnar of which the patient was unaware. Sometimes, in spite of a good anatomical and physiological result, the economic result was bad owing to the patient's mental condition. Sometimes it was bad on account of “local ataxia”—that is to say, the function seemed to be entirely restored if the patient's attention was concentrated on the part concerned, but it quite failed if the movements were attempted in the dark or when the patient's attention was occupied by something else; this failure of the automatic function was due to the imperfect recovery of some of the afferent conducting paths.

Sir William Thorburn then gave statistics of results obtained by various operators in this and other countries. Good results seemed to be obtained in one- to two-thirds of the cases; very good results were seldom obtained, but complete failures were fairly numerous. He had no faith at all in the efficacy of grafting operations, and he pointed out that some of the bolder operations, such as nerve-stretching, transference of the nerves to new beds, and tendon transplantation, did much towards rendering grafts unnecessary. It had been found that certain general principles in results usually held good: large muscle masses producing coarse movements recovered very much better than small muscle groups controlling finer movements; function nearer the trunk was more readily restored than function at a greater distance; homogeneous nerves, such as the musculo-spiral, recovered better than nerves controlling more complicated movements.

Concerning the long time taken to obtain recovery after operation, it had been estimated that downgrowth of the axon, as determined by means of Tinell's sign, proceeded at the rate of about one millimetre per day; recovery of function in the hand therefore took much longer than recovery in the upper arm. Much of the time, however, in either case was taken up in establishing connexion of the nerve fibres with the end-organs. The work that had been done at Manchester showed that a quite perfect result was never obtained, the recovery of sensation being particularly poor. The best functional results were obtained with the musculo-spiral nerve. If a surgeon obtained good economic results in 50 per cent. of his cases he was doing well; if he obtained them in 75 per cent. he was not only doing well but was exceedingly fortunate.

Mr. PERCY SARGENT (London) said that the conditions in war wounds, which introduced so many serious complications, were entirely different from those of simple experimental cases. There were two main

groups of cases—the one in which operations were done for the restoration of the conduction of nervous impulses, the other in which they were done to improve disordered function. He proposed only to consider cases in which restoration of conduction was attempted by means of resection of damaged nerve tissue and suture of cut surfaces. He believed that end-to-end suture was the only means of obtaining restoration of conduction, and that other operations need scarcely be considered. In this connexion he described a case in which a lateral anastomosis of nerves was done with anatomical failure. He stated that no useful result had ever been obtained by carrying out a graft operation. In considering the results he assumed that only the best technique had been employed—that is to say, the operations had been done without deep fixation sutures, with accurate suturing of the nerve sheath; that a gap of at least 1 mm. was always left between the ends of the nerve-fibres; that no sort of wrapping had been put round the sutured nerve; and that there had been no sepsis. He made no distinction between “primary” and “secondary” suture.

What, then, were the prospects of the operations in general? In considering this question, he had come to the conclusion that “end-results”—that is to say, final results, as distinguished from “late results”—had not yet been obtained in the majority of cases. The criteria that were used in examining cases were the condition of the nerve in conduction capacity, its electrical reactions, the power of voluntary contraction, and sensibility of various kinds. The interpretation of results was often very difficult. Sometimes very misleading cases were put forward as evidence, and in illustration of this Mr. Sargent mentioned a case of nerve-grafting, which had been reported as a success, but was found on critical examination to have been erroneously described. If sensation alone was considered, too rosy an impression might be obtained. The power of voluntary movement considered by itself was apt to be misleading, owing to the education of other muscles that sometimes took place with the production of unsuspected “trick movements.” If there appeared to be a return of voluntary movement in the absence of sensory recovery these trick movements must always be suspected. Results differed widely in different nerves; they were specially good in the musculo-spiral, but very much worse in complicated nerves, such as the median and the ulnar. The muscles of the forearm recovered much better than the muscles of the hand. Sometimes the sense of position was wholly absent when the results, as regards the voluntary movements and electrical reactions, were good. It was very important that sensibility should be restored, especially in the case of the median, but the motor function of the ulnar nerve was of little importance. Late results might be bad owing to coincident psychological factors. The value of re-education might be very great, but the same degree of success must not be expected in all cases, since individual capabilities varied greatly, some men being normally incapable of any but very clumsy movements. So-called “trophic changes” were often the result of neglect or immobilisation for too long a time, and could be improved by suitable treatment. A disordered vaso-motor activity was usually due to an irritative lesion and might affect the end-result, since it was accompanied by nutritional effects.

Mr. Sargent referred, in conclusion, to the condition of continuous or chronic pain, known as causalgia. Sometimes this tended slowly to abate; in other cases no treatment was of any avail, though operations should always be tried. Causalgia was often associated with very little loss of movement or sensibility, and the trophic changes associated with it could be arrested. Alcohol injections of various strengths often relieved the condition, but if it were necessary to inject concentrated alcohol a lesion of the nerve would be produced from which there would be no recovery.

Dr. MAUD FORRESTER-BROWN (Edinburgh) gave elaborate statistics derived from an examination of the results following 643 operations done in Sir Harold Stiles's clinic. Her figures illustrated many of the points mentioned in Mr. Sargent's paper. She recorded two cases which showed complete motor recovery after nerve-graft or flap operations, and stated that very good results had been obtained from tendon transplantations. Tinell's sign was obtained in most cases, but in some was entirely absent.

Mr. COPLAND (Leeds) appeared to be in agreement on most points with Mr. Sargent. He mentioned, however, some cases of nerve-grafting in which there had been positive results. In one case in which seven inches of the median nerve had been supplied by a graft there

had been some return of sensibility in the median area; in two other cases there had been some improvement of motor function. In the technique of the operation he believed that it was of great importance to make a new bed for the nerve to lie in. He pointed out that the trick movements mentioned by Mr. Sargent may be of value from the economic point of view, and should therefore be encouraged; they also produced a better blood-supply to the limb. The most rapid recovery that he had met with had been in a case of suture of the median nerve, in which recovery was complete in nine months. The use of warmth he believed to be of great importance in after-treatment.

Mr. J. L. JOYCE (Reading) said that too much stress was being laid on the operation, which was merely an episode in the treatment. The operation of choice was end-to-end suture, but among 121 cases he had found that 22 could not be treated in this way. For these 22 he had used autogenous grafts, homologous grafts, double lateral implantation, and tendon transplantation. The results obtained compared favourably with those following end-to-end suture. Double lateral implantation, or, as he preferred to call it, a pedicled autogenous graft, gave better results than a free autogenous graft. He felt encouraged to pursue his investigations further.

Mr. ROWLEY BRISTOW (London) agreed in the main with Mr. Sargent. He drew attention to the fact that those cases which showed early signs of nerve regeneration did not necessarily give better end-results than those which were more delayed. He had seen six cases of graft operations; these were all complete failures, except one, in which the signs of recovery were probably due to the muscles having acquired a connexion with other nerves. It was possible for an isolated nerve to show in this way signs of apparent recovery. Tendon transplants had given good results.

Mr. NAUGHTON DUNN (Birmingham) said he had found that, contrary to his expectation, nerves sutured under tension recovered better than when there was no tension. This emphasised the importance of Mr. Sargent's statement that there should always be a small gap between the sutured ends, and reduced the number of cases in which a graft need be attempted. He had never seen any signs of regeneration in a grafted nerve.

Dr. L. E. SHORE (Cambridge), as a physiologist, presented a point of view which was somewhat different from that of the other speakers. He said that the exact way in which the axis-cylinders grew down was obscure, but they appeared to be under a chemiotactic influence. One axis-cylinder usually divided into a bunch of fine fibrils, which then grew out in all directions and seemed to hunt for the right track to grow into; some were successful, but many of them failed to find a sheath. He described the way in which Professor Langley first showed that nerve fibres were twisted in the nerve like the strands of a rope; this fact made him look upon any attempt to obtain anatomically accurate union as quite hopeless. There appeared to be two classes of motor nerve fibres with physiologically different functions; one was controlled by the lower brain centres and moved large muscle masses, the other by the higher centres and produced the finer movements. He believed that the economic result of operations depended largely on the degree of recovery of epicritic sensibility. He finally inquired of the surgeons whether a gap in a nerve had ever been bridged by shortening the bony skeleton of the limb.

Sir WILLIAM THORBURN, in reply to Dr. Shore, stated that shortening of the limb had been done on several occasions. The operation was particularly suitable for the upper arm.

Mr. SARGENT, in conclusion, dwelt on the difficulty experienced by most surgeons of achieving absolute honesty in the interpretation of their own results, and he applied the criticism to himself as much as to anybody else. He repeated his conviction that no true recovery after a graft operation had ever been obtained.

Chronic Suppuration in the Accessory Sinuses of the Nose.

The paper by Mr. HERBERT TILLEY (London) on this subject was not of a controversial nature; it was intended

rather for the instruction of those who had not thought much about the diagnosis of sinus suppuration, which was nearly always the underlying cause of a so-called chronic nasal catarrh. Mr. Tilley discussed the origin, signs, symptoms, and the treatment of sinus suppuration, and illustrated his points with anatomical drawings and diagrams. He followed up his lecture with a demonstration of the methods of endoscopy on the afternoon of the same day.

Demonstrations.

The secretaries of the section had arranged in addition to the discussions a series of very successful demonstrations in the afternoons. On June 30th a demonstration was given by Mr. P. P. COLE and Mr. H. D. GILLIES (London) of the methods and results of plastic surgery of the face. The surgery of the war wounds of the face has been fully described in Mr. Gillies's recent monograph, and is therefore widely known. The photographs and cases shown were for the most part already familiar to those who had seen the book. A more novel feature was the exhibition of several patients who had been treated by plastic surgery for conditions met with in civil practice. These included an epithelioma of the nose, lupus of the nose, excision of the lower jaw, and cleft-palate. The results obtained were a vindication of Mr. Gillies's faith in the brilliant future which lies before plastic surgery.

On two afternoons, June 30th and July 1st, Major MEURICE SINCLAIR gave a practical demonstration of the modern methods of treating fractures. He first showed the use of a Thomas's splint as first-aid treatment for a fracture of arm or leg, and then carried out in detail the whole process of putting up a patient with a fractured femur in the Sinclair net-bed. The treatment of a series of different fractures was demonstrated and was made realistic by having the splints in position on men posing as patients.

On July 1st Mr. ARTHUR COOKE and Dr. J. W. MACNEE showed how to test prospective blood donors for their blood groups and demonstrated the whole process of blood transfusion, first by means of a Kimpton's tube and then by the citrate method, employing an open operation on the donor and Robertson's bottle as originally described.

The demonstrations were all well attended and were highly instructive.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

WEDNESDAY, JUNE 30TH.

PUERPERAL SEPSIS.

THIS section opened on June 30th, with Dr. HERBERT WILLIAMSON, as President.

Mr. VICTOR BONNEY (London), in opening the discussion on Puerperal Sepsis, said that the solution of the problem how to prevent, and how to cure, septic infection of the puerperal uterus, necessitated the correct answering of three questions: 1. What is the original source of the organisms? 2. How do they get into the uterus? 3. What is their exact situation by the time they have produced symptoms of sepsis? He was of opinion that the infection, in most cases, originated from an intrinsic source, and not from organisms conveyed from patient to patient. Speaking broadly, the occurrence of the disease at the present day is sporadic, not epidemic, a point in favour of the view he had expressed. He thought from a consideration of the facts that the antiseptic precautions in use up to the present time have been efficient in preventing infection in which septic organisms are conveyed from one patient to another. There was no doubt that organisms capable of producing puerperal sepsis commonly pre-exist in a woman, particularly in relation with the anoperineal skin. In other words, the commonest cause of puerperal sepsis was, in his opinion, faecal infection. Although it was difficult to apply Listerian principles in their entirety to obstetric work, he advocated the exclusion of the perineum and anus as far as possible by fixing over it a large gauze-pad soaked in some antiseptic. Practical sterilisation of the peri-anal skin may be effected by the use of a 1 per cent. solution of equal parts of crystal violet and brilliant green in half-and-half alcohol and water. A 2 per cent. solution of iodine

is also effective. Mr. Bonney considered that for all purposes except Cesarean section, even for examination only, the lithotomy position is preferable. With regard to the modes by which organisms reach the uterus, he thought that although in a few cases they may be carried there by hands or instruments, in the large majority of instances they reach the organ by natural currents. The speaker observed that, as a rule, puerperal sepsis is not associated with the retention of gross fragments of placental tissue in the uterus. Furthermore, the organisms are situated in the uterine wall almost from the beginning of the infection, and soon extend beyond it via the veins or lymphatics.

The problem of treatment of puerperal sepsis is, he said, very difficult. Immediate sterilisation by flavine or Milton's solution, where sepsis is suspected, is probably valuable in preventing extension. The common practice, however, of giving an intra-uterine douche with the idea of washing away and killing the organisms in the uterus is senseless and harmful. Mr. Bonney was not in favour of scraping the uterus, unless it could be carried out quite early and be followed by the insertion of irrigating tubes in the Carrel-Dakin manner. Under such conditions he thought that it would be the means of arresting the infection in many cases. It must be done if at all within 12 hours of the temperature rising. As to the value of vaccines and antitoxic serums in the treatment of puerperal sepsis he was frankly pessimistic. He was, however, favourably impressed with the results obtained by ligaturing or excising the ovarian vessels and lymphatics.

Surgical Treatment of Puerperal Sepsis.

Mr. BECKWITH WHITEHOUSE (Birmingham), in an opening paper on the Surgical Treatment of Puerperal Sepsis, observed that a study of the statistical tables of the Registrar-General showed that the risks of sepsis to the parturient woman were very real. There could be little doubt from the results published that the existing everyday methods of treatment were unsatisfactory, and that in this respect the science of obstetrics had not advanced appreciably within recent years. He then proceeded to contrast the pathological conditions obtaining in a septic puerperal uterus with those in a deep-infected muscular shell wound. The similarity was very close, both as regards the nature of the infecting organisms and the position of the same. Mr. Whitehouse traced the evolution of treatment of war wounds and referred to the very great advance that was made by the institution of the Carrel-Dakin method. By applying Carrel's continuous irrigation to the septic uterus from the earliest stage possible he was of opinion that the present mortality rate might be lowered. He had within the past two years treated 15 cases of very severe sepsis by this method with only one death. With regard to curetting the septic uterus, there are undoubtedly grave risks both of extending the infection and also of perforating the soft tissues. He had found it a useful asset to the Carrel-Dakin method, but sounded a note of warning with regard to its general adoption and use by irresponsible individuals. It should not be employed unless continuous irrigation with hypochlorite solution was instituted at the same sitting. The speaker then referred to the possibilities of intravenous medication in those cases of puerperal sepsis where organisms have reached the blood stream. He had recently with good effect been employing a solution of flavine, 1-1000 in normal saline, intravenously in cases of puerperal septicæmia and pyæmia. Flavine has the great advantage for intravenous injection that it is a non-protoplasmic poison and has no effect upon the red or white corpuscles.

Intravenous Protein Therapy in Puerperal Septicæmia.

Dr. A. E. GOW (London) spoke in support of intravenous protein therapy in puerperal septicæmia. He said that with the introduction of intravenous injection of "peptone" as an accessory to sensitised vaccine a considerable step forward in the treatment of pyogenic septicæmia had been made. Of the various preparations of peptone on the market Witte's is the best for the purpose. Ten grammes are dissolved in 100 c.cm. of

water containing a little sodium bicarbonate. The solution is boiled and filtered, and from 8 to 10 c.cm. are given intravenously as the first dose. The injection is made slowly, Nolf's technique being employed. The occurrence of a rigor following the injection is an excellent sign, and in the speaker's experience often marked the turning point of the disease. Peptone treatment is a useful accessory to other methods, but Dr. Gow did not make any extravagant claim to its success in all cases. As regards autogenous vaccines, the causal organism, in most cases the *Streptococcus pyogenes*, can be isolated more quickly from an intra-uterine swab than from the blood stream.

Serums and Vaccines in Puerperal Infection.

Dr. LEITH MURRAY (Liverpool) continued the discussion with a paper upon the Value of Serums and Vaccines in the Treatment of Puerperal Infection. He was of opinion from a consideration of the literature that the employment of serums or vaccines is not attended by results so satisfactory as to exclude the use of other forms of inoculation therapy. He urged that steps be taken early and not late in the course of a case of septicæmia when probably nothing could save the patient. He did not agree with the customary division of puerperal infection into toxæmic and septicæmic groups. The distinction is merely between a grave and a very grave condition. In the interval when diagnosis by blood culture is being made, he thought that it is not only legitimate but highly advisable to give antistreptococcus serum. With regard to vaccine treatment Dr. Leith Murray was of opinion that a stock vaccine is never advisable in acute cases. Autogenous vaccines, however, especially when combined with serum, appear to be of distinct service. The best results are obtained in the subacute cases. In conclusion, he expressed the opinion that the patient's best interests are not served by the usual present-day practice of treating cases of puerperal septicæmia in ordinary fever hospitals. Public health authorities must be informed that an expert on the treatment of puerperal fever cannot be created in six months and that the services of an officer specially trained for this work should be obtained.

Discussion.

Mr. S. L. GRAHAM (Birmingham) referred to the work at the Women's Hospital, Birmingham, where a special ward for the treatment of puerperal sepsis was established. From an experience of 800 cases with a mortality of 143 he was frankly pessimistic about the present methods of treatment. He had tried vaccine and serum therapy for two years and had now given it up. His present treatment consisted essentially of good nursing with intra-uterine douching. The majority of the patients in the puerperal ward slept out of doors.

Dr. EARDLEY HOLLAND (London) observed that treatment is certainly very chaotic as shown by the diversity of methods described. He thought that one of the most important points in the discussion was the autogenous method of origin. He was in complete agreement with Mr. Bonney's suggestion, and for this reason advocated the abolition of vaginal examination in favour of rectal examination in obstetric work. For ten years he had not made a vaginal examination except in complicated cases.

Dr. AMAND ROUTH (London) observed that no definite proof had been brought forward that either *B. coli* or the *Streptococcus faecalis* were always the causal germs, and for this reason he was not prepared to agree with Mr. Bonney that puerperal infection was usually of autogenous origin. With regard to treatment, he thought that intra-uterine douching was of great importance immediately after delivery of the placenta in all cases of complicated labour.

Dr. FRANCES IVENS (Liverpool) called attention to the preparation of a patient before labour commenced. She was of opinion that if the same precautions were taken as before a surgical operation the incidence of puerperal infection would be much reduced. She also advocated the employment of serum therapy at an early stage of the disease.

Dr. J. P. HEDLEY (London) said that one of the great difficulties in dealing with puerperal infection was to know which patients were going to get well and which were going to die. It was also important, amongst the diversity of methods advocated, not to kill the patient with treatment! He was impressed with the results of the Carrel-Dakin method described by Mr. Whitehouse, and he intended to apply the same when the occasion arose.

Dr. A. LAPHORN SMITH (London) felt that a great deal of the mortality at present attached to puerperal infection could be avoided if adequate surgical precautions were taken before labour commenced. He drew attention to the importance of adequate drainage of the uterus and stated that he did not believe in curetting a septic uterus.

Dr. R. C. BUIST (Dundee) observed that in arguing from results from any new methods two facts must be remembered. One was the natural response of the patient to treatment, whatever it may be. The other was the incorrectness of deducing principles without having recourse to very long lists of cases.

Dr. F. DEIGHTON (Cambridge) spoke in support of the remarks of Dr. Ivens and Dr. Laphorn Smith. One of the difficulties of adequate surgical preparation before obstetric work was the fact that the principle was not generally recognised.

Dr. R. J. JOHNSTONE (Belfast) called attention to the important difference that existed between puerperal sepsis of the uterus and septic infection of adjacent parts. As regards the origin of infection he was in accord with the views expressed by Mr. Bonney, and had held this opinion for ten years. He was not so pessimistic about treatment as some speakers appeared to be, and thought that reasonably good results could be expected if proper care was adopted. He did not curette the uterus as a routine but only when shreds of sloughing endometrium were being discharged.

Dr. R. J. ROWLETTE (Dublin) spoke in favour of vaccine therapy, and especially of autogenous vaccines. If it was impossible to isolate the infecting germ from the blood-stream a uterine swab should be taken. He advocated a small initial dosage, the first dose being not greater than 5 millions.

Dr. F. EDGE (Birmingham) was of opinion that vaginal douching, except in hospitals, should be abolished as a routine treatment of puerperal infection, and advocated thorough examination under an anæsthetic in all bad cases.

Dr. PARRY referred to the difficulty of treating a confinement as a surgical operation in general practice, and thought that nearly all cases of puerperal fever were due to infection by the doctor or nurse in attendance.

Dr. PECHÈRE (Brussels) was in complete agreement with what various speakers had said about prophylaxis. In Belgium puerperal sepsis was very common in the larger towns, although it was not frequent in the maternity clinics, where proper precautions were taken. He spoke in favour of the use of peptone and serum therapy.

The PRESIDENT, in closing the discussion, drew attention to the need for more detailed examination of post-mortem material. He also thought that obstetricians in the various large centres throughout the country should periodically meet and discuss results in order to further any special line of inquiry or treatment. With regard to Mr. Bonney's theory of autogenous infection, he did not consider that the acceptance of the same relieved the practitioner one iota of his personal responsibility. As to Mr. Whitehouse's treatment by the Carrel-Dakin method, he thought that the author intended that such treatment should be carried out in institutions. There were dangers in indiscriminate curetting, and although it had undoubtedly its place in treatment, the indications at present were not such as to warrant its general adoption. He fully concurred with Dr. Leith Murray's suggestion that the treatment of puerperal fever should be severed from the general fever hospital, and Birmingham had led the way in this respect.

SECTION OF ELECTRO-THERAPEUTICS.

FRIDAY, JULY 2ND.

Presidential Address.

Dr. A. E. BARCLAY (Manchester), in his presidential address to the section, referred to the granting, by the University of Cambridge, of a diploma in medical radiology and electrology, and the establishment of a complete course of study in these subjects in preparation for it. The granting of this diploma opened a new era in the history of radiology and electrology, and a higher standard than has been possible in the past will be attained in the future. The need for a full course of instruction and a diploma was greater than had been realised. An entry of nearly 30 had been obtained for the first examination in July, 1920, and more than 12 had commenced the second course of training for the next examination in December, 1920.

Mr. H. S. SOUTTAR (London) opened a discussion on *The Diagnosis and Treatment by Electrical Methods of Paralysis Due to Nerve Injuries.*

Electrical methods were of special value in affording an early indication of recovery after injury. A change in the nature of the response of the muscles to galvanic current, from slow to quick, was a sign that recovery would take place, and this change could be noted long before the return of faradic excitability. Regarding electrical treatment, the opener held the opinion that electrical currents were of much value, mainly on account of their power to cause the paralysed muscles to contract and do work. Faradic currents were also of value because they caused normal muscles in the same limb to contract, thereby helping the circulation in the limb, protecting the tendons from adhesions, and keeping the joints free.

Dr. W. J. TURRELL (Oxford) attached much importance to the use of electrical methods for diagnosis. The faradic and galvanic currents were of most value for this purpose, and could provide information on the condition of the nerve and the degree of degeneration of the muscle.

Dr. F. HERNAMAN-JOHNSON (London) said that the condenser method of testing would give an early indication of the arrival of the regenerating motor nerve at the muscle. He believed that, in treatment, muscles should not be made to contract until some voluntary power had been regained.

Dr. NOEL BURKE (London) spoke of the electrical testing of motor nerves exposed during surgical operation and of the information that could be obtained by this process on the physiological continuity of nerve trunks in the region of injury.

Dr. C. WORSTER-DROUGHT (London) described the condenser method of testing reactions. In his experience with some 2000 cases, this method provided accurate indications whether the nerve injury was sufficiently severe to demand surgical treatment. After nerve suture and the expiration of a period of delay, testing by condenser discharges decided whether recovery was taking place, before return of voluntary power.

Dr. HOWARD HUMPHRIS (London) mentioned the use of the melted paraffin-wax bath in preparation for subsequent treatment. The reddened, moist, and slightly greasy condition of the skin rendered the latter ideal for massage.

A paper by Dr. ROBERT KNOX (London) on

Radiography of Tumours of the Chest

was read by Dr. SHILLINGTON SCALES owing to the absence of the author due to illness. The paper dealt with the tumours found in the chest wall, in the mediastinum, and in the lungs. The X ray appearance of these tumours was described and their differential diagnosis was fully considered. The paper was illustrated by several lantern slides. In the discussion that followed, Dr. IRONSIDE BRUCE (London), Dr. H. BLACK (Birmingham), Dr. HOPE FOWLER (Edinburgh), Dr. FLORENCE STONEY (Bournemouth), and Dr. J. HALL-EDWARDS (Birmingham) took part.

Dr. S. GILBERT SCOTT (London) read a paper on *The Diagnostic Value of the Renal Outline.* After referring to its appearance in normal kidneys, kidneys of abnormal size, and kidneys with abnormal

shadows, he described his method of determining the relation of abnormal shadows to the kidneys by means of the respiratory excursion of the kidney and the presence or absence of movement of the abnormal shadow. If the latter moved to the same extent and in the same direction as the renal shadow the abnormal body must be connected to the kidney.

Professor J. GOODWIN TOMKINSON (Glasgow) read a paper on

X Ray Therapy in Oriental Sore.

Three cases were treated. One of these, which had received ionisation earlier without apparent benefit, was cured by nine weekly applications of X rays filtered through $\frac{1}{2}$ mm. aluminium. Each dose was a half sabouraud. The second case was also cured. The third was still under treatment and was improving.

EXHIBITION OF SURGICAL AND ELECTRICAL APPLIANCES, DRUGS, AND FOODS.

I. Surgical Apparatus, including Electrical Appliances and Scientific Instruments—Continued from p. 96.

A review of Division I. can be well completed by a reference to four exhibits of particular interest. The Sanborn Company, of Boston, Massachusetts, exhibited the Benedict Basal Metabolism Apparatus which has recently been brought into use to determine the oxygen consumption of patients in the treatment of goitre, hyperthyroidism, anaemia, diabetes, and so forth. This ingenious apparatus, designed by Dr. F. G. Benedict of the Carnegie Nutrition Laboratory, measures the inspired and expired air, so that the amount of oxygen entering the lungs and the amount leaving can be determined, the difference representing that used in the body, a "respiratory quotient" being thus established. The determination needs no laboratory analysis, the oxygen consumed being shown by a direct reading from the scale of the apparatus. Another instrument shown here was a combination blood-pressure outfit and stethoscope for use in surgical operations, giving advantages to both operator and anaesthetist. Mr. W. H. Pettifor, of 11, Victoria-street, London, S.W., presented a range of "electrical aids for the deaf" of various pitches, and possessing different wave-form characteristics. This was described as a special form of telephone made up of three parts, the receiver or ear-piece, the transmitter or microphone, and a small dry battery. A test instrument was also shown, enabling a prescription to be written to give the most suitable pitch, sound-wave form, and volume of sound for each individual case. The test set enables a combination of 90 different instruments to be prescribed. This suggestion of standardisation attracted considerable interest. An apparatus generating oxygen at will was exhibited by the Hydrogen, Oxygen, and Plant Company, Ltd., of 1, Albemarle-street, Piccadilly, London, W., the gas being generated from simply the contact of "oxylithe" with water. This substance is stated to be prepared by an electro-chemical process from sodium peroxide. There is complete control over the apparatus as to the quantity of oxygen evolved. The suggestion is that the possession of this apparatus by the physician makes him independent of a cylinder supply. A related gas, of course, is ozone, the production of which was illustrated in the exhibit of Ozonair, Ltd., of 96, Victoria-street, Westminster, London, S.W. There were here shown the latest designs of apparatus producing ozone from the air for, amongst other things, the treatment of respiratory diseases, for purifying the air of the sick room, for the sterilisation of water, and for the bleaching of coloured materials.

II. Drugs, including Antiseptics.

Colloids, synthetics, organic arsenical preparations, and glandular extracts seemed to occupy most of the attention of both visitor and exhibitor, and the display was quite comprehensive in character, attracting general interest.

The disclosures of the ultra-microscope formed a real scientific show, and facilities were given for an inspection of this with objects in view at the stall of British Colloids, Ltd., The Crookes Laboratories, 22, Chenies-street, Tottenham Court-road,

London, W.C. When correctly staged the Brownian movement and the orbit of the ultra-microscopic particles were fascinating to watch, reminding the observer of the phenomenon of the spintharoscope (radium bombardment). A well-defined series of colloidal preparations was shown, including metals, non-metals, and one alkaloid—quinine. As is correctly stated, the essentials are not new drugs; they are simply familiar medicaments in a new form—a form in which their therapeutic efficiency is remarkably increased, while objectionable side issues are to a large extent avoided. Under the term "oscols" Messrs. Oppenheimer, Son, and Co., Ltd., of 179, Queen Victoria-street, London, E.C. (who claim to be the introducers of the advantages of colloidal medication), exhibited a series of metallic and non-metallic colloids of a permanent character, their condition being controlled by careful laboratory examination. The exhibit included examples of palatinoids, the preserving power of these capsules being noteworthy. Phosphorus, ether, organic extracts are thus kept unimpaired.

The progress achieved in the chemical manufacture of British-made synthetics and drugs found significant illustration in the exhibit of Messrs. Boot's Pure Drug Co., of Nottingham, where was presented a series of admirable specimens, including aceto-salicylic acid, acetanilide, saccharin, hexamine, butyl, chloral, orthoform, and certain alkaloids and glucosides. The antiseptics shown included mercuric potassium iodide and chloramine-T. All branches of pharmacology were well represented at the artistic exhibit of Messrs. Burroughs, Wellcome, and Co., of Snow Hill Buildings, London, E.C. Notable amongst the things shown guaranteeing purity, accuracy, and reliability were the arsenic synthetics replacing effectively German salvarsan and neo-salvarsan. Organo-therapeutic preparations formed a feature of this exhibit. In addition to apparatus for oxygen inhalation with or without alcohol, and an interesting laboratory device for the determination of nitrogen in compressed oxygen, and of carbon monoxide in gas mixtures, Messrs. Reynolds and Branson, of Leeds, exhibited a number of pharmaceutical preparations made on skilled lines. Such were their series of elixirs, gargles, and concentrated tinctures. General interest was shown in the exhibit of bacterial vaccines at the stall of Messrs. Parke, Davis, and Co., of 50, Beak-street, Regent-street, London, W., produced in the inoculation department of St. Mary's Hospital under the supervision of Sir Almroth Wright. The series included the pneumonia phylacogen and hormone preparations, and glandular substances. The correct choice of a liquid paraffin for medicinal purposes was illustrated by the Wm. Browning Co., Ltd., of Albert Works, Park-street, London, N.W. Apart from the pure oil itself with an approved viscosity a new product was shown called "semprolax," which by a special process renders liquid paraffin palatable, free from oily taste and appearance, and yet containing, according to claim, 80 per cent. of the intestinal lubricant. Messrs. C. J. Hewlett and Son, of 35-42, Charlotte-street, London, E.C., were to the front with their well-known original preparations, including the mist, pepsinæo. c. bismutho, and the physiologically standardised extract of ergot, both of which have stood the test of clinical experience for a good many years. The art of reducing fluids to fine spray was well illustrated at the stall of Mr. Frank A. Rogers, of 327, Oxford-street, London, W., where was shown a profusion of atomisers and spray apparatus adapted for close and effective application to nose and throat of various medicaments, whether of an oily nature or merely aqueous solutions.

Drug standardisation was amply exemplified in the exhibit of the Hoffmann-La Roche Chemical Works, Ltd., of 7 and 8, Idol-lane, London, E.C. Specimens were exhibited of digalen, a sterile solution of the active principle of the fresh leaves of digitalis showing a uniformity of composition, and therefore therapeutic activity. In addition were exhibited specimens of omnopon, a fluid presenting the total alkaloids of opium in a soluble form and suitable for injection. A stable combination of omnopon with scopolamine is also prepared.

(To be continued.)

THE LANCET.

LONDON: SATURDAY, JULY 17, 1920.

Health in the Last Year of War: the Influenza Figures.

THE year 1918 was, for the bulk of the inhabitants of this island, the most strenuous and the most anxious time within human memory. It opened with a period of unexampled depression during which the manhood of the country was fighting against an ever-advancing army in the field, while the women and children of the country were carrying on bravely at home in circumstances bordering more and more on actual privation. True, the tide soon began to turn, but it was not until late in the year that the strain was relaxed. Before this occurred the country was visited by a scourge of epidemic disease without parallel since the cholera outbreak of 1849. Anyone conversant with the effect of such outward conditions on the physical health of the community must have prophesied a rate of mortality higher, much higher indeed, than that of quiet and peaceful times. Sir BERNARD MALLET, whose report we summarise on another page, nevertheless declares the year to have been one of extraordinary healthiness. The civilian deaths during the year numbered 587,828, making a death-rate of only 17.1 per 1000. Of these deaths only 10.5 per cent. were those of infants under 12 months of age. Enteric fevers were so diminished as to have lost their significance as a cause of death. Cancer showed an appreciable decrease on the previous year's record. The first impression produced on the reader by the Registrar-General's figures is one almost of incredulity, attended with a growing thankfulness to those who had the ordering of public hygiene and whose faithful work was rewarded in so dramatic a manner. The intensive industry and compulsory temperance of the population were certainly contributory factors.

The influenza epidemic did not, of course, run out during the year, and this fact has induced the Registrar-General to take the exceptional course of issuing a separate report¹ which has only just appeared. The main features of the epidemic have long been known, but this panoramic survey, while confirming many of the conclusions reached from partial views of the outbreak, puts some in a truer perspective and modifies or disproves others. The deadly character of the disease has never been brought out so clearly as in the table showing that in the fourth quarter of the year 1918 the mortality among women of 25 to 30 was 540 times greater than the average for the same quarter of the four preceding years. On the other hand, we are informed, contrary to usual belief, that pregnancy did not add appreciably to the risk of death, and in the circumstances it could indeed hardly have been expected to. The report brings out the great similarity in type of the disease throughout the whole of the country. Heart disease, for instance, was uniformly recorded as a complication much more frequent in the first wave than in the second. Bronchitis, too, became less common in all areas as time went on. In two important particulars the epidemic differed materially from that recorded by Dr. WILLIAM FARR.

In 1847 twice as many people (in proportion to population) died in the more insalubrious parts of London as in the less unhealthy. The pandemic of 1918-19 was no respecter of persons either in regard to health or wealth. In the first wave it is true that the wealthier parts of London and the healthier boroughs were let off lightly, but in the second wave Divess shared the fate of Lazarus. In 1847 Dr. FARR noted that influenza especially attacked persons labouring under other zymotic diseases; in 1918-19 there was no evidence of any such association.

It looks, indeed, as though the overwhelming intensity of the infection over-rode any initial variations due to environment or local resistance. The first wave, which spent itself by the end of July, hit the towns much more severely than the rural areas, and was at its worst in East Lancashire and West Yorkshire. It was followed by an interval of four weeks in which the mortality stood at the modest figure of fourfold its normal rate. The second wave respected no region, however remote and isolated, and levelled out all claims of relative immunity. Places like Jarrow, which practically escaped the first bout, suffered with special severity from the second. In the north, when the second wave seemed to be abating, it returned again with a fresh lease of virulence, due apparently to a reinfection from the south. The intermission of mortality between the second and third waves was neither so prolonged nor so complete as that between the first and second. Late involvement seemed to confer a certain amount of protection in the first wave, but no advantage accrued in this respect in the other waves. Of local variations in intensity the most that can be said is that on the whole the county areas were progressively less severely affected as one proceeds south. Who desires to study in detail the record of his own area will find material for so doing in this amazingly complete survey. The epidemiologist will be able to draw from it lessons of value for the future, but not without prolonged study.

Consultation Fees.

WHATEVER changes may have occurred in the methods and habits of consulting physicians and surgeons or in the circumstances of the patients sent to them for advice, their fees have remained unchanged for a generation or more as far, that is, as the discreet cloud of mystery that surrounds consultation fees admits of clear comparison. We know that the traditional two guinea fee, when it represented a vastly greater purchasing power than it now does, was often reduced in the case of the patient whose financial handicap was indicated to the consultant by the family doctor who sent him. But we imagine that the handicapping was always to the disadvantage of the consultant, who drew no larger fee whatever the affluence of patients who visited him. In contrast therewith a sliding scale of fees has always been in use by the general practitioner of medicine, because his knowledge of the financial standing of his various patients was generally no less intimate than that of their physical frailties. Naturally, this cannot be the case to the same extent in consulting practice, and may account for the anomaly of the fixed fee. It is an arrangement which, to speak frankly, has worked none too well in the past, and with the redistribution of wealth which has recently taken place is likely to work still less well in the future. We called attention a fortnight ago to an experiment in graduating consultation fees initiated at the suggestion of a

¹ Cmd. 700, H.M. Stationery Office, price 1s. 6d.

London business house. The scheme contemplated for a person with an income of £350 or under a reduction of the operation fee to 10 per cent. of the normal, and of the fee for consultation and treatment to 25 per cent. The rest of the scale is given in brief as follows:—

Adjusted income.	(a)	(b)	Adjusted income.	(a)	(b)
Under £350 ...	10 %	25 %	Under £700 ...	30 %	45 %
" £400 ...	12½ "	27½ "	" £800 ...	40 "	50 "
" £450 ...	15 "	30 "	" £900 ...	45 "	55 "
" £500 ...	20 "	35 "	" £1000 ...	50 "	60 "
" £600 ...	25 "	40 "	" £1500 ...	60 "	Full.

The "adjusted income" shown in the first column includes any private means as well as the salary of the employee, and is to be ascertained by deducting one-fifth of the total income on account of a wife, and one-tenth on account of each child, or other dependent member of the household. Cols. (a) and (b) represent the proportion of fees payable for (a) operations; (b) consultations, treatment, or nursing home fees. A minimum of 1 guinea is fixed for a single visit.

It will be seen that the full consultation fee will not be paid until the patient has an income of more than £1000 a year, and the full operation fee not until his income exceeds £1500 a year. Seeing that a series of physicians, surgeons, and specialists of repute have accepted these conditions it is evident that some, at all events, of those in consulting practice in London are prepared to admit that their normal fee is in the nature of a maximum, the important question being, having regard to the modesty of the maximum, for how many patients is it applicable, and, in particular, for how many is it too low. The scale outlined above, be it noted, only defines the proportion of the fee payable without fixing its actual amount. It is open, therefore, for any physician or surgeon accepting such an arrangement to fix the norm at any level which he chooses; and obviously if he is to accept the reduced fee in a large proportion of the cases in which he previously received the full one it would be only fair for the consultant, especially for the consultant physician, to place his norm at a higher level than that of the now usual 2, 3, or 5 guineas, and in so doing obtain from the affluent a proper equivalent for his skilled advice.

In the scheme we have quoted the employer makes inquiry into the patient's income, including any private means which he may possess. Inquisition of this sort would, we think, be found to be resented except as applied impersonally to the staff of large business firms. In other cases it seems to us that the income-tax return might be used, instead of, for example, any employer's voucher. The information given by a patient to his medical attendant is already of so confidential a nature that he need hardly hesitate to disclose to him also the amount of his net income. This information would still remain between the surveyor, the doctor, and the patient, and the patient would not be taking his employer into his confidence. Such a system would enable the principle of graduating consulting fees to be carried out on a larger scale than that at present suggested.

Outdoor Medical Officers of the Ministry of Health.

THE invitation of the Ministry of Health to candidates for appointments upon a projected outdoor staff was accompanied at the time that it was made by the information that a committee would consider the applications and make recommendations to Dr. ADDISON thereon. As we announced at

the time, this committee included medical men of high standing, representing different parts of the country, the Civil Service Commissioners, and the Ministry of Health, but for obvious reasons it was not thought convenient to announce the personnel of the body until its delicate work of selection had actually been performed. In another column of this issue of THE LANCET there will be found the names and qualifications of the Selection Committee, its report to the Ministry of Health upon the applications received for the appointments under the Ministry, and the names of the medical men whose applications for engagement have been successful. These appointments embody the conception of medical referees, set out by the British Medical Association. Their holders will have functions which are primarily administrative, but the early duties may be largely clinical, inasmuch as the officers will take the place, as official referees, of the consultants who have been acting hitherto in this capacity under private arrangement with the Approved Societies. The new officers will act as expert advisers for the authority responsible for the clinical service, and will probably have supervisory power in the administration of the service.

It will be seen, therefore, that the appointments form an important link in the chain of medical organisation, bringing the local health authorities into touch with the hospital and special services that may be provided in the future. This is of particular interest because with all the vast opportunities for organised development which underlie the activities of the new Ministry of Health, there is an inevitable risk that some of the plans of reform, so far from simplifying medical practice, may actually complicate it by the erection of various forms of administration and supervision. As a matter of fact, the new outdoor staff of the Ministry of Health should fit in well with the development of Primary Health Centres, which is the first great principle of the Report of the Consultative Council of Medical and Allied Services. At a meeting of the Bath and Bristol Branch of the British Medical Association held in Bristol last week Lord DAWSON expounded this Report, and had the advantage of doing so in a county where regulations had been proposed for medical practice which in some of their essential features were an actual forecast of the recommendations of the Consultative Council. For Dr. MIDDLETON MARTIN, medical officer of health of the county of Gloucester, with the assistance of the practitioners in the district, has devised a scheme under which general practitioners could be brought into relation with primary or cottage hospitals, staffed by themselves, which could be connected with the secondary hospitals in the larger towns, that is with the great voluntary institutions as we know them. The Gloucestershire scheme has not reached the stage of fruition, but it will now develop with the added prestige of forming a pattern to the country of the method by which the general practitioner can at last use his powers for good in a proper environment. And while the Report of the Consultative Council proposes to bring into connexion the general practitioner's ordinary work, centring around primary centres, with the work of consultants and teachers, as represented by the activities of the voluntary hospitals, the new appointments by the Ministry of Health of outdoor medical officers should bring the local health authorities into touch with all forms of domiciliary and institutional medical service.

Annotations.

"Ne quid nimis."

TYPHUS IN POLAND.

THE appeal from the committee seeking funds for the help of Poland is reinforced by such information as is received, but it has been difficult heretofore to get out of Poland a full account of the typhus epidemic. Dr. Norman White's public lecture on Thursday evening, under the auspices of the Chadwick trustees, will have contributed greatly to public enlightenment. In the *Military Surgeon* (Washington, D.C., U.S.A.) for June there is a report by Colonel Harry L. Gilchrist, Medical Corps, U.S. Army, dated in January, 1920, which tells how appalling the situation was then, and from it we quote below. Colonel Gilchrist was sent to Poland in May, 1919, by the President as head of the American Typhus Fever Expedition, detailed generously from the United States Army Medical Corps.¹ The expedition works under the Polish Minister of Health. Typhus, says Colonel Gilchrist, has been epidemic in Poland for four years (1920 will make the fifth); it became far more serious after the armistice. It is always being freshly imported by returned prisoners and refugees from Russia and the Ukraine, of whom two and a half millions entered Poland in 1919, less than half of them Poles. In Russia and the Ukraine the epidemic originates. People there die by thousands, their bodies piled in great heaps awaiting burial. Poland realises their condition, and out of charity does not refuse entrance to these pitiful refugees. She establishes quarantine stations, but people come in such crowds they cannot be handled, and so the epidemic is spread. Bolshevik commanders, it is stated, release typhus sufferers from Russia in trains near the frontier, so that they must drift into Poland. As a rule Denikin's garrisons left behind were garrisons of typhus fever. Galicia is also suffering. Whole towns are crippled, schools and business suspended. In North-East Poland American inspectors report disease infecting nearly every home. Poland has been so ravaged by armies that destitution is widespread. Mostly people live on potatoes, beets, and other vegetables; sometimes they have no fuel to cook them. Yet Poland is making efforts to deal with typhus, and is doing its best even to train doctors and nurses, but it lacks financial resources and sanitary supplies for this overwhelming emergency. Major Willis Baker, one of Colonel Gilchrist's inspectors, wrote from his station:—

"843 beds in hospital, mostly typhus, but also tuberculosis, dysentery, relapsing fever, and small-pox. An August convoy of 200 had 30 cases of typhus on arrival, 150 more cases developed in a few days. The staff remained uninfected till December, when 400 prisoners were passing through daily, of whom 80 per cent. were infected, and disease then broke out among officers and workers, and of eight doctors seven got typhus. Patients are lying on the floor or on board platforms. There are no beds. There is no bedding, but straw and paper blankets; no hospital clothing, no medicines, no instruments, no hospital linen or equipment, almost no lavatories or latrines. The whole place is foul and terrible. A great shortage of eating utensils; 800 simple pots to feed 800 patients, who are in the most extreme misery."

Lieutenant-Colonel Register, Medical Corps, U.S. Army, died of typhus in January last, but, knowing well their risks, the whole American expedition volunteered for another year of service. Colonel Gilchrist sums up the needs of Poland as: soap in thousands of tons, hospital linen and under-clothing in hundreds of thousands of sets, hospital equipment for thousands and thousands of beds; and declares that unless checked "this epidemic will threaten the whole of Europe. The situation at present is getting beyond control." We commend to our readers the appeal we published last week from the committee begging them to tell their friends how extreme is Poland's need.

THE TOXIC FACTOR IN MIGRAINE.

As in the case of many functional diseases, the pathology of migraine is not definitely known and is the subject of controversy. A reflex neurosis arising from irritation of organs such as the stomach, uterus, or eyes, a vaso-motor disturbance, and a toxæmia (of the nature of which there is dispute) are some of the hypotheses which jostle one another. In the *Presse Médicale* MM. Ph. Pagniez and A. Nast have brought forward strong evidence in favour of the toxic nature of the condition. Their paper has the merit of producing experimental evidence in place of the speculations with which eminent writers have for a generation regaled the profession. They point out that in the great majority of cases of migraine the crisis cannot be provoked at will, but the majority of patients know conditions which favour its appearance. In some it is some article of diet, a glass of wine or a liqueur; in others muscular fatigue; in others emotions or departure from regular habits, such as times of meals, going to bed, or rising. But when the patient exposes himself to the cause of the attacks the crisis usually does not occur immediately, but after a period of several hours or even of more than a day. There is therefore a period of elaboration in the organism before the crisis. Another important fact is that many patients notice that for days after an attack they can take whatever they like with impunity. These facts appear to have a humoral basis, as the following case shows. A strong, intelligent man had been migrainous since childhood. He received considerable benefit from small doses of peptone before meals, but when the treatment had been stopped for a certain time the crises reappeared. Several causes would start an attack. Among these was the taking of chocolate, particularly milk chocolate, but when he took a cachet of peptone before meals he could commit with impunity imprudences which he usually carefully avoided. His case was investigated experimentally. Half a gramme of peptone was given before meals. Experimental meals consisting of bread, milk, and chocolate, in quantities up to 100 g., were given, without preliminary administration of peptone. Digestion leucocytosis followed and migraine did not occur. Then the peptone was stopped, and two days later he was given a meal containing 60 g. of chocolate with the same result. But an experimental meal, given nine days after stopping the peptone, was not followed by leucocytosis but by leucopenia (3700) and an attack of migraine. It is noteworthy that the prophylactic treatment conferred an immunity which lasted several days after its discontinuance. Similarly, an attack of migraine is followed by a period of immunity. MM. Pagniez and Nast conclude that the essence of the disease is some humoral modification which renders the subject liable to an attack—a sort of temporary anaphylaxis. Upon the rapidity with which this state is reconstituted after an attack depends the degree of the disease. The exact nature of the humoral modification is not known. It is not surprising that if the crisis can be provoked by certain articles of diet, the action of which is comparable to anaphylaxis, the disease may be cured or suspended by a therapy of "alimentary anti-anaphylaxis."

THE SUPPLY OF SPIRITS IN HOSPITALS.

It is interesting to note that during the Committee stage of the Finance Bill, which was taken last week, Clause 2, which provided for the continuation of the increased medicine duties was agreed to, as also was Clause 3 dealing with increased duties on potable spirits. On reaching Clause 4, however, which refers to the use of spirits in medicinal preparations or for scientific purposes, a discussion arose on the question of allowing a rebate on all spirits used in hospitals on prescription. The point at issue was whether hospitals should be permitted to obtain potable spirits free of duty. One argument put forward in favour of this concession was that during the war military hospitals, guided by medical representation, obtained spirits free of this tax. When the spirit is mixed with drugs there is a partial

¹ THE LANCET, March 26th, 1920, p. 671.

abatement allowed, but in the case of potable spirits there is no such abatement. The Financial Secretary of the Treasury opposed the suggestion on the ground that the greatest possible care was required not to leave any holes by which evasion of the duty on wines and spirits was possible. If such a concession were made, he maintained, the Board of Customs would be entirely in the hands of the staffs of hospitals throughout the kingdom, and it would be a very great responsibility to throw on them. The use of potable spirits in our hospitals, according to statistics, appears to have decreased considerably, and so the fact that the suggestion of a rebate on such supplies was rejected may not prove to be a very serious economic matter.

SCLERODERMIA AND PITUITRISM.

IN 1917 Alibert described for the first time under the name of scleremia a morbid syndrome characterised by cutaneous sclerosis, afterwards re-named sclerodermia. Although its association with other affections, such as myxœdema, exophthalmic goitre, and the frequent occurrence of pigmentation have suggested a theory of a plurality of sclerodermic forms, little has been achieved in lifting the veil which surrounds its true pathogenesis. With the prevalence of new views regarding the importance of the endocrine glands, theories of the pathogenesis of sclerodermia naturally gravitated towards these fresh ideas, and invoked as causative agent changes in the thyroid, pituitary, or suprarenal capsule. We are indebted to Dr. Izar for the publication of a case with full details, which throws some light on the causation of sclerodermia and its relation to pituitrism.¹ The patient was a girl, 7 years of age, who developed an extensive sclerodermia on the neck, face, thorax, and antero-external surface of the limbs. The cutaneous thickening was so great that the child resembled a wax doll. The mother and sister were short and fat, suggesting the pituitary type, and a radiogram of the child's skull showed some enlargement of the sella turcica. But the chief interest of the case lies in the result of the pharmaco-dynamic reactions. For instance, neither adrenalin, pilocarpine, atropine, endothymin, endothyroidin, nor endo-ovarin gave rise to any reaction worthy of mention, while on the other hand injections, both of total pituitary extract (hypophysin) and of pituitin in doses of $\frac{1}{4}$ – $\frac{1}{2}$ c.cm., induced rise of temperature, increased arterial tension, and slowing of the pulse to a marked degree. With this positive reaction a therapeutic course of pituitary extracts was commenced, with the result that after the sixth daily injection of $\frac{1}{2}$ c.cm. the sclerodermic lesion began to recede. By the forty-ninth day, after 16 injections of hypophysin and 16 of pituitin, there only remained some pseudo-œdema on the neck, forearms, and legs, and treatment was continued by the administration of half a tablet of Byla's hypophysin on alternate days by mouth. All signs of the skin affection had disappeared at the end of six months. The striking and beneficial action of this opotherapeutic cure would seem to establish without doubt the pituitary origin of the cutaneous lesion in this case.

SMOKING AT WORK.

THE question of labour efficiency in relation to tobacco-smoking has been revived in a prominent fashion by the increasing practice of smoking in the workshops. It seems clear that in many cases the practice is tolerated by authority, and the anti-tobacco protagonists may soon be expected to put forward their case against this innovation, based on the ills to which it may give rise, when the evils of nicotine will be emphasised. The abuse of tobacco is well recognised, and that the smoke from it, especially when inhaled, has definite toxic properties must be admitted. A few years ago we furnished analyses from THE LANCET Laboratory showing how the smoke from cigarettes, pipes, and cigars differs, amongst other things, in nicotine content.² The results showed that while nicotine is a highly

poisonous constituent of tobacco, the evidence was not conclusive that this alkaloid invaded the consumer to the extent hitherto accepted. There was more nicotine found in the smoke from the cigar and pipe than from the cigarette, the suggestion being that in the last case a large proportion of the nicotine was destroyed by combustion. There are, however, other bases found, probably of a toxic character, and there is present also an appreciable amount of carbon monoxide. Certain processes which entail the manipulation of poisonous materials, such as lead and arsenic, must always contra-indicate smoking, since the toxic substances may be carried to the mouth by soiled fingers, pipe stems, or cigarettes, and the same contra-indication exists where there is risk of fire or explosion. But when all is said we must face the fact that those who have acquired the habit of smoking are more contented when permitted to indulge in it and are irritable when it is prohibited. To-day the psychology of the worker is rightly receiving more and more attention, and a real and strong case must exist before anything which promotes contentment is prohibited. Smoking on an empty stomach—e.g., before breakfast and more than three hours after the last meal—seems to be felt injuriously by many subjects, while smokers generally appear to hold that smoking directly after meals promotes digestion; the belief is widespread and calls for consideration. The custom now rapidly increasing in industrial work of introducing short mid-morning and mid-afternoon pauses, during which time tea-trolleys go round with light refreshment—a practice recommended as long ago as 1861 by medical men—provides reasonable opportunities for allowing smoking. Cases have even been quoted of increased output following permission to smoke; but we are not aware of any data of scientific value either to justify or to contradict this claim. The question, which is not without importance, calls for investigation, and, we suggest, is worth the attention of the Industrial Fatigue Research Board.

THE SERUM TREATMENT OF CHANCROID.

THE amount of research carried out in connexion with the serum treatment of *ulcus molle* is surprisingly small and, apart from Ito's investigations, little has been done to explore this particular field. In a paper read early this year at a meeting of the Swedish Medical Society, Dr. J. Reenstierna¹ gave an account of his experiences with a serum prepared at Professor Pettersson's bacteriological laboratory, and tested in about 100 cases of chancroid with bubo formation at Professor Almkvist's venereal department of the Karolinska Institute. The serum was obtained from large rams which were given intravenous injections of increasing quantities of killed and living cultures of Ducrey's streptobacillus. In the "autoreferat" of his paper, Dr. Reenstierna does not give further particulars as to the dosage of these injections which were repeated over a long period before the serum was used. In the matter of complement fixation, the serum was proved to be definitely specific, but agglutination tests could not be satisfactorily carried out owing to the granular clumping which suspensions of Ducrey's streptobacillus exhibit even before the addition of agglutinating substances. Other laboratory tests of the specific properties of this serum could not be carried out for want of suitable material, but the clinical tests were strikingly convincing. Within 24 hours of an intramuscular injection of 10 c.cm. of the serum marked improvement was observed; the inguinal glands became less painful and swollen, and the overlying skin less inflamed. Dr. Reenstierna has attempted to augment the therapeutic action of this serum by the addition of killed, thermogenic bacilli, such as typhoid bacilli, and he advocates this double-barrelled therapy because, after many years' experience of the serotherapy of gonorrhœal arthritis, he has found the benefits obtained to be proportional to the degree of fever provoked. Ducrey's streptobacillus, like the gonococcus, is very sensitive to a temperature only a few degrees above

¹ La Riforma Medica, May 22nd, 1920.

² THE LANCET, April 6th, 1912.

¹ Svenska Läkaresällskapets Förhandlingar, Hft. 3 and 4, 1920.

the normal body temperature, and an injection which provokes fever should, in Dr. Reenstierna's opinion, prove beneficial on this account. His achievements certainly seem to confirm his claims, and Professor Almkvist, who took part in the following debate, paid an appreciative tribute to the indefatigable efforts which had yielded such promising results. Negative confirmation of the specific properties of the serum was found in its failure to provoke any reaction, favourable or otherwise, in seven cases wrongly diagnosed as chancroid. The aspiration and bacteriological examination of pus in the inguinal glands revealed staphylococci, not Ducrey's streptobacilli. As for the cases of true chancroid, they usually cleared up altogether within little more than a week. Usually two injections were given with an interval of four or five days, and in no case did a relapse occur. Dr. Reenstierna publishes details of a case of suppurating bubo which had persisted for more than a year and which responded with dramatic effect to serotherapy.

ACUTE EPIDEMIC ENCEPHALITIS.

WITHIN a period of three days at the latter end of May three cases were admitted into the wards of the London Hospital presenting symptoms of encephalitis with unusual features and all ending fatally. The clinical manifestations accord in a striking manner with those of a condition described by Sicard and Kudelsky at a meeting of the Société des Hôpitaux de Paris on Jan. 23rd of this year under the name of "encéphalite aiguë myoclonique." It is of interest to note that Sicard points out that the cases he described are in turn similar to those described by Dubini in 1846 under the name of electric chorea. The London Hospital cases are described in detail in this week's issue of THE LANCET by Dr. Arthur W. M. Ellis, assistant director of the medical unit in that institution, in a paper which should be of interest to all our readers. He points out that similar cases have been recorded in France since Sicard and Kudelsky's original description by a series of observers, while cases of identical character have been observed and recorded in Switzerland, America, and Germany. Dr. Ellis has not been able to find any cases recorded in this country previous to those observed by himself, though myoclonic contractions have been described as a late sequel of lethargic encephalitis. The first of Dr. Ellis's cases was a labourer aged 17 years, the second a child of 6, the third a Jewess aged 28, who was pregnant. The initial symptom in every case was vomiting, followed in two of the three by severe pain in the lower part of the abdomen and the thighs. Obstinate constipation was invariable and in every case complete retention of urine, necessitating frequent catheterisation, occurred. Severe and complete insomnia progressing to wild delirium seems to be an important and distressing feature, and apparently the only drug inducing any degree of quiet in these patients is hyoscine. The most characteristic feature, however, is the shock-like contractions, chiefly of the abdominal muscles, occurring at the rate of 30 or 40 to the minute, and often more marked on one side. The forceful character of these movements is shown by the fact that in two of the patients they caused a pulling down of the lower ribs and a lifting upwards of the pelvis. The pupils were widely dilated in all these cases, but the dilatation disappeared with the onset of coma. Profuse sweating, leading to sudaminal or miliarial rashes, also occurred, and there was a moderate degree of fever. Speech was jerky, indistinct, and slurred in two of the cases, but frequently rational periods occurred in the intervals of the delirium. Some paresis of the eye muscles occurred in one case and was doubtfully present in a second. Nystagmus was observed in one of the cases only. A well-marked leucocytosis with increase in the polymorphonuclears was present in all three—a point of distinction between these cases and ordinary lethargic encephalitis. The cerebro-spinal fluid was clear, but showed slight increase in cells and in the protein content in all three. Dr. Ellis was

fortunate enough to obtain autopsies on two of his three cases, the only gross lesion observed being a moderate degree of cerebral congestion. He proposes to report on the histological conditions found later. He is to be congratulated on the prompt publication of the details of the clinical features of his cases, thus drawing the attention of the profession in this country to an interesting condition. Attention has already been pointedly directed to the lethargic type of encephalitis, but in addition to this now classic picture there is the paralysis agitans type observed in this country, the hyperkinetic form first described in Australia in 1918, the myoclonic form dealt with in this note, while neuralgic, choreic, psychic, and tabetic forms have been adduced. Economo in his most recent article¹ points out how widely the disease has varied in different areas and at different times in the same area since the first outbreak of the epidemic. In the present Austrian epidemic the somnolent ophthalmoplegic cases only number about 30 per cent. of the total, and at least 60 per cent. show excitation phenomena of one kind or another. In this country, where the number of cases has been much smaller than on the continent generally, the great variations which may occur in the clinical picture have not been so widely recognised. It is to be hoped that practitioners encountering cases in their practice similar to those which Dr. Ellis puts on record will examine and record them carefully or transfer them to institutions where they can be scientifically investigated. Dr. Ellis rightly points out that the identity of causation of his cases with that of the lethargic cases of encephalitis, though probable, has yet to be established. We hope that the London Hospital Medical Unit will continue work on the lines indicated by Dr. Ellis's communication, for collective investigation of other cases, if, as seems likely, they become more frequent, may yield results of great interest and importance.

THE BOGUS "DOCTOR."

THE medical profession is unfortunate in that it apparently offers more temptation than any other to fraudulent persons to pretend to be members of it with a view to victimising their fellows. Having once done so, they find the way of the transgressor easy so long as it remains open, and even after having been caught and convicted they are apt to resume their evil courses at the earliest opportunity. In short, the bogus doctor is a criminal who is a specialist, just as much as the abortionist, who is sometimes a bogus doctor, the trained pickpocket, or the blackmailer; and he is assisted by the credulity of others. Medical men, if not actually brought in contact with him, and even those who are, do not always take the precaution of establishing his identity, and laymen, who fall into his hands, being usually members of the more ignorant classes, have not sufficient knowledge or sufficient observation to detect him. A man convicted at Bow-street a short time ago and sentenced to nine months' imprisonment with hard labour was an example of the sham-medical recidivist, for he had quite recently undergone 18 months' imprisonment for posing as a medical practitioner and signing death certificates when acting as a locum tenens. He was an instance of ability to impose easily upon a selected victim, for he had obtained £25 from a cartage contractor, presumably a business man, by pretending to be a medical practitioner and to have invented a cure for cancer which he valued at £40,000—a story which would have secured his undoing if told to a medical man. The impostor had, as a matter of detail, first made the acquaintance of the prosecutor at a watering place by saluting him as a brother freemason, and giving correctly the signs and tokens of the degree which he claimed to have. Whether he was in fact a freemason, and how far the belief that he was one assisted him in obtaining the money, is not stated, but it may be worth the while of medical men to note the case. We do not recall any previous instance of this method of self-introduc-

¹ Wien. klin. Wochenschr., 1920, xxxiii., 329.

tion or self-recommendation being employed for the purpose of fraud. It will therefore be as well to remember that the credentials of a stranger desiring to be engaged as a locum tenens or accepted as a medical colleague are not to be considered with less care because he also alleges the common bond of freemasonry. As has been suggested above, to judge from the frequency with which cases are reported in the newspapers, no other learned profession is so liable to temporary adoption for nefarious purposes as medicine. Sham officers abound, but they are a temporary by-product of the war. The Church and the Law offer few opportunities to the dishonest, and sham solicitors, if they occur occasionally, can only expect success so long as they can keep out of contact with genuine members of the legal profession. This is not easy for them to do, and their sphere of operations is thus narrowed considerably.

PARAPLEGIC MULTIPLE SCLEROSIS.

Dr. Archibald Church,¹ of Chicago, states that a generation ago multiple sclerosis was regarded as an absolute rarity in the United States, mainly because only the classical picture, as manifested by nystagmus, intention tremors, and scanning speech, was recognised. On the other hand, like other neurologists, he has found that *formes frustes* and aberrant types have recently been recognised much more frequently than formerly. In addition to the generalised classical form of multiple sclerosis, which is infrequent except as the terminal phase of the fractional forms, he has encountered the following clinical types: a cerebellar type, a rare early manifestation of the disease which tends to become fully developed fairly rapidly; an optic atrophy type, which is not uncommon and only slowly merges into the generalised condition; a paraplegic type, which appears to be the commonest of all, and which very slowly assumes the features of upper level and cerebral involvement; and lastly, a very rare monoplegic type. The paraplegic type to which Dr. Church draws special attention begins with weakness or clumsiness in one leg or foot, which not infrequently leads to stumbling or rather severe falls. This irregularity in gait may improve or seem to subside completely after being present for weeks or months, but there is only a temporary remission. Contrary to previous descriptions, sensory disturbances, both subjective and objective in character, are not uncommon in this type of multiple sclerosis. The most important signs of the disease when the lower extremities are mainly or exclusively affected are ankle clonus, Babinski's sign, and unilateral partial or complete abolition of the umbilical reflex. A lack of uniformity in the affection of the reflexes on the two sides is frequently observed. In the late stage sphincter control is not rarely affected, and actual incontinence may occur. Signs of cerebral involvement commonly supervene sooner or later, such as squint, diplopia, optic atrophy, irregularities of the visual field, speech defects, and even mental peculiarities. Treatment is usually disappointing. Dr. Church has tried several cases with intensive courses of mercury, salvarsan, and the iodides, as well as with fibrolysin, without observing any favourable results.

RESEARCH STUDENTSHIPS AT ST. MARY'S HOSPITAL.

—The recently formed Institute of Pathology and Research at St. Mary's Hospital has established three post-graduate research studentships with a view to the training of recently qualified men or women in methods of research. Each studentship is of the value of £200 a year, and is tenable for six months, with the possibility of extension to 12 months. Preference is to be given to graduates from St. Mary's Hospital Medical School. The appointment may be held in any one of the seven departments of the institute, according to the choice of the individual student. The following have been appointed for the first six months in the departments of anatomy and embryology, general and special pathology, and chemical pathology respectively: Dr. Ida Mann, Dr. Joan Ross, Dr. Samuel Simms.

MINISTRY OF HEALTH: OUTDOOR MEDICAL STAFF.

As announced in THE LANCET of March 20th the Minister of Health appointed a Committee to assist him in the selection of suitable candidates for the post of Medical Officer of the Ministry of Health, for which applications were then invited, in the following terms:—

The medical officers will be required to perform such duties as may be assigned to them by the Minister from time to time. These duties will include:—

- (a) Acting as referees on questions of incapacity of insured persons for work, and giving second opinions on questions of diagnosis and treatment;
- (b) Organising the arrangements for work of part-time medical referees for the area; and
- (c) Assisting in the administration of the Insurance Medical Service.

The country will be arranged in territorial areas, and each officer will be required to reside in the area assigned to him.

The rate of remuneration will be £1000 per annum, rising by annual increments of £50 to a maximum of £1400, and no war bonus will be payable in addition thereto. Officers appointed to this scale will be established civil servants with the usual pension rights.

Applicants who are of the age of 50 years and upwards who may be appointed will not be established, but will receive a total remuneration fixed at £1400 a year (non-pensionable), and in such cases the appointments will be for a limited term of years.

Applicants must be medical men of not less than ten years' standing, and preference will be given to those having wide experience of general practice, especially amongst the industrial population.

The Committee have presented to the Minister the following report:—

Report.

1. We have the honour to report to you the result of our deliberations pursuant to your minute of March 24th, 1920, whereby we were appointed members of a committee to consider applications of candidates for appointment as medical officers of the Ministry and to make recommendations to you of candidates suitable for appointment.

2. The total number of applications received was 1325. Of these, 1242 were in respect of English and 83 in respect of Welsh appointments (certain candidates applying under both heads).

3. In our consideration of the Welsh applications we have had the benefit of the assistance (in accordance with your desire) of Dr. Meredith Richards.

4. After careful consideration of the applications and testimonials of the candidates we selected for interview 159 of those applying for English appointments and 14 of those applying for Welsh appointments.

5. The instructions printed on the form of application required each candidate to give the names of three persons able to speak from personal knowledge of his qualifications for these appointments. In the case of each candidate selected for interview these persons were communicated with before the interview, and the replies received were duly considered.

6. We think it proper that you should be informed as to the considerations by which it has appeared to us that our judgment should be guided in the selection of candidates suitable for the discharge of the duties of these posts. We have carefully weighed, in regard to each candidate, the evidence of his qualifications in the following respects:—

(a) Medical degrees and diplomas, academic distinctions, and early clinical experience in resident appointments at hospitals.

(b) General clinical experience: (i.) in general practice, especially practice among the industrial population in England or Wales; and (ii.) in other fields of medical practice, whether in civil life or as a medical officer of His Majesty's Forces.

(c) Experience as a medical referee, whether in connexion with National Insurance, Workmen's Compensation, the work of the Ministry of Pensions, or otherwise.

(d) Experience of National Health Insurance administration, as a member of an Insurance Committee or otherwise, and other administrative experience—e.g., in public appointments or in military service.

(e) Professional and public reputation in the district in which the candidate practised.

(f) Personal characteristics, including presence, force of character, and tact.

7. Certain candidates were pre-eminently suitable in some of the foregoing respects and some in others; and we have not attached preponderating weight to any particular set of considerations, but have viewed each candidate's qualifications on balance as a whole.

8. We regarded it generally as important that candidates should not be below 40 or above 55 years of age, but a few

younger or older candidates were otherwise so exceptionally well qualified that we have not hesitated to include them among those recommended as suitable for appointment.

9. In the case of the Welsh appointments we attached importance to a knowledge of the Welsh language.

10. We submit for your consideration the enclosed list of names of 55 candidates suitable for appointment in England and names of 8 candidates suitable for appointment in Wales.

11. Our report to you would be inadequate without the expression which we desire to make, of our sincere appreciation of the great assistance rendered to us by Dr. McCleary and Mr. Fitzgerald, the secretaries of the Committee. Their efficiency, diligence, and courtesy have reduced to a minimum our labours in endeavouring to do full justice to so large a number of candidates of whom a relatively high proportion merited interview.

The Report is signed by the whole of the Committee of Selection, which was constituted as follows:—

T. W. Shore, M.D., M.R.C.S., L.R.C.P. (Chairman), Dean of the Medical School, St. Bartholomew's Hospital.

E. Collingwood Andrews, M.D., B.Sc., Consulting Medical Officer to the Hampstead Maternity Home.

Sir Hamilton A. Ballance, K.B.E., C.B., M.S., F.R.C.S., Surgeon, Norfolk and Norwich Hospital.

(Nominated by the Civil Service Commissioners.)

Professor R. A. Bolam, O.B.E., M.D., M.R.C.P., Honorary Physician, Skin Department, Royal Infirmary, Newcastle-on-Tyne; Professor of Medical Jurisprudence, University of Durham.

H. G. Dain, M.B., M.R.C.S., L.R.C.P., Chairman of the Birmingham Insurance Committee.

Professor Arthur J. Hall, M.D., F.R.C.P., Senior Physician, Sheffield Royal Hospital, Professor of Medicine, University of Sheffield.

Sir Walter Kinnear, K.B.E., Controller of National Health Insurance, Ministry of Health.

E. J. Maclean, M.D., M.R.C.P., Senior Gynaecologist, Cardiff Infirmary, Lecturer on Midwifery, University College, S. Wales.

J. Smith Whitaker, M.R.C.S., L.R.C.P., Senior Medical Officer, Ministry of Health.

G. F. McCleary, M.D., W. T. Fitzgerald, Joint Secretaries.

The Selected Medical Officers.

Dr. Addison has decided, with the concurrence of the Treasury, that 30 whole-time officers should be appointed for England and three for Wales at the inception of the scheme, and the following are the selected medical officers for England, leaving one vacancy to be filled:—

G. Ashton, 2, Palatine-road, Withington, Manchester.

S. A. Bontor, Great Berkhamstead.

T. L. Bunting, Scotswood-on-Tyne.

T. M. Carter, Burnley, Westburn-on-Trym, Bristol.

W. Davidson, 91, Wimborne-road, Bournemouth.

W. Duncan, 169, Ashley-gardens, S.W. 1.

J. Gray Duncanson, 1, Ranelagh-villas, Hove, Sussex.

G. W. Eustace, Maltravers-street, Arundel.

A. Heath, 66, Otley-road, Harrogate.

A. Linnell, Paulerspury, Towcester.

M. G. McElligott, 23, Standish-gate, Wigan.

W. Moir, Belgrave-square, Darwen.

D. G. Newton, 7, Gladstone-road, Sheffield.

J. Orton, Great Heath House, Coventry.

R. Paterson, 247, Boundary-street, Liverpool.

B. A. Richmond, 34, Bromley-road, Catford, S.E.

W. Rigby, 16, St. Alban's-place, Blackburn.

B. M. H. Rogers, 14, Mortimer-road, Clifton, Bristol.

J. Dill Russell, Osman House, Fortis Green, E. Finchley, N.

H. L. Rutter, 31, West Parade, Newcastle-on-Tyne.

E. W. Selby, 13, Hall Gate, Doncaster.

H. Sinigar, Western-road, Southall, Middlesex.

G. K. Smiley, 20, Kedleston-road, Derby.

M. R. Taylor, 64, Churchfield-road, Acton.

J. F. Walker, Rocklands, Clifton-terrace, Southend-on-Sea.

H. A. Whitcombe, Locharwoods, Formby, Liverpool.

E. H. Willock, 91, London-road, Croydon.

C. R. Wood, 75, Langdale-road, Hove.

A. Young, 43, Collegiate-crescent, Sheffield.

For Wales the following have been appointed:—

J. Evans, Bron Menai, Carnarvon.

D. N. Morgan, Gilfach Goch, Nr. Bridgend.

T. R. Llewellyn, Penygraig, Glam.

For England it has also been decided to appoint four medical officers of higher grade, who will be designated divisional medical officers and will superintend the work of the whole-time and part-time medical officers in the divisions assigned to them respectively. The following have been appointed to these posts.

Divisional Medical Officers.

R. E. Crosse, 68, Nightingale-lane, S.W.

A. Fulton, Armoy, Old Basford, Nottingham.

C. H. Milburn, 13, York-place, Harrogate.

H. J. Neilson, Shandon, St. George's Hill, Weybridge.

In Wales the senior medical officer of the Ministry for that country will discharge the functions, as regards the outdoor medical staff, which are discharged in England by the divisional medical officers.

Part-time Appointments.

In addition to these whole-time appointments it is understood that part-time appointments will later be considered, when payment will be made by session or by case. Applications for these appointments have not yet been invited.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on July 8th, Sir GEORGE MAKINS, the retiring President, being in the chair.

The PRESIDENT reported the re-election of Sir Anthony Bowlby and Sir D'Arcy Power and the election of Mr. Francis James Steward to fill three vacancies in the Council (see THE LANCET, July 10th, p. 104).

Diplomas in Public Health were granted jointly with the Royal College of Physicians to 35 candidates found qualified at the recent examinations.

The Council passed a vote of thanks to Colonel L. A. Waddell, late I.M.S., for his valuable gift of crania to the Museum, and to Sir Charles Tomes for presenting to the Museum the sections of teeth made and used by him and his father in their researches into the comparative anatomy of the teeth.

The following recommendation was received from the Committee on the Special Primary Examination for the Fellowship:—

That on account of the delay which has occurred in the demobilisation of officers in the Army in the East (India, Persia, Mesopotamia, &c.) an additional First Professional Examination for the Fellowship under war conditions be held in May next, and that it be definitely stated that such examination is to be the last held under special war conditions.

This recommendation was approved and adopted.

A letter, dated July 5th, was read from Sir Frank Colyer resigning his membership of the Board of Examiners in Dental Surgery in anticipation of the expiration of his period of office on Oct. 14th next, and his resignation was accepted.—The PRESIDENT stated that the vacancy thus occasioned would be filled up at the next meeting of the Council.

The Council elected the following professors and lecturers for the ensuing year:—

Hunterian Professors.

Arthur Keith: Six lectures on the Principles of Craniology Applied to Clinical and Racial Problems.

William Sampson Handley: One lecture on the Pathology and Treatment of Lupus.

Walter Goldie Howarth: One lecture on Mucocoele and Pyocoele of the Nasal Accessory Sinuses.

Charles Walter Gordon Bryan: One lecture on the Early and Late Effects of Injuries of the Diaphragm, with special reference to wounds jointly involving thoracic and abdominal viscera.

Harry Platt: Two lectures on the Surgery of the Peripheral Nerve Injuries of Warfare.

Alfred Geo. Thimbrell Fisher, M.C.: One lecture on Loose Bodies in Joints.

Arris and Gale Lecturers.

Frederick Wm. Edridge-Green: One lecture on the Cause and Prevention of Myopia.

Joseph Faulkner Dobson: One lecture on the Function of the Kidneys in Enlargement of the Prostate Gland.

John Howell Evans: One lecture on the Azygos System of Veins in their Association with Surgical Affections.

Erasmus Wilson Lecturer.

Samuel George Shattock: Six demonstrations on pathological specimens in the Museum.

Arnott Demonstrator.

Arthur Keith: Six demonstrations on the contents of the Museum.

Thomas Vicary Lecturer.

Sir D'Arcy Power, K.B.E.: One lecture on the Education of a Surgeon under Thomas Vicary.

Sir Anthony Bowlby was elected President for the ensuing year. Sir Charles Ballance and Sir John Bland-Sutton were elected Vice-Presidents.

A vote of thanks to Sir George Makins for his services as President during the past three years was passed.

The following were admitted as Honorary Fellows, and were entertained to dinner at the College by the Council in the evening: Dr. A. Depage, Brussels; Dr. Pierre Duval, Paris; Dr. J. M. T. Finney, Johns Hopkins University; and Dr. Charles H. Mayo, Rochester, U.S.A.

REGISTRAR-GENERAL'S EIGHTY-FIRST ANNUAL REPORT, 1918.

Sir Bernard Mallet's report on the vital statistics of England and Wales in 1918 has recently been issued, addressed to Dr. Addison, as Minister of Health. The Registrar-General summarises his report in a comprehensive introduction, in which the year under notice is declared to have been one of extraordinary healthiness, notwithstanding the exceptional prevalence of influenza towards its close. The civilian deaths in 1918 numbered 587,828, and corresponded to a rate of 17.6 per 1000 of the estimated population—which rate is reduced to 17.1 by correction for age distribution of the living. The extent of the reduction has been increased during the war by the withdrawal from the civilian population of males at an age when mortality is below the general average. But this effect has been masked by the high influenza mortality of 1918 which occurred at these ages. If the record of 1918, apart from epidemic incidence, had not been an extremely good one, comparison with past years would have been far less favourable. And if a true idea of the public health is desired it is necessary to ascertain what the mortality would have been in the absence of this epidemic. "The first 40 weeks of the year showed a very good record indeed," in spite of epidemic influence: it would therefore be wrong to speak of 1918 as a period of excessive fatality, without discriminating between the mortality due to influenza and that due to other causes. It is unfortunate that the real trend of mortality during the three years 1916-18 should have been obscured, first by the deterioration of the male population already referred to, and, in addition, by the epidemic fatality of the last few weeks of 1918.

The following is a summary of the chief features of the mortality of the year:—

Of the total deaths registered in the course of 1918 only 10.5 per cent. were those of infants who had not completed their first year of life. This is by far the lowest rate of *infant mortality* recorded, the percentage so recently as 1901-10 having been 22.6. The change is partly due to increased influenza fatality at the higher ages, but mainly to the rapid fall of infant mortality, and to reduction in births. In terms of total births, infant mortality in 1918 was equal to 97 per 1000, or 9.3 per cent. below the average in the ten preceding years. It is one of the lowest rates on record, only three previous years having experienced infantile mortality of less than 100 per 1000 births. The provisional figures for 1919 show a rate of 89 per 1000, or 2 per 1000 below that of 1916, which was the lowest rate hitherto attained. The comparison, however, is affected by the fact that in 1916 the birth-rate was falling, whilst it was rising in 1919; and when the necessary allowance has been made for these movements the rates for the two years appear to be about equal.

As compared with the preceding year enteric fever, measles, and diarrhoea showed a lower mortality, whilst scarlet fever, diphtheria, and whooping-cough showed a higher. The deaths from *enteric fever* numbered 950, of which 65 occurred among non-civilians. The resultant mortality, 26 per million living, is the lowest ever recorded in this country. To some extent the fall is due to absence, on foreign service, of a large number of men of the ages at which enteric fever mortality is highest. The remarkable fall from 300 deaths per

million living in 1869 to 26 in 1918 may be followed in a new table, which indicates that the loss of life from this eminently preventable disease is now only one-third of what it was even ten years ago. The disease is rapidly losing its significance as a cause of death in this country.

The great *influenza epidemic*, which commenced about midsummer in 1918, increased the deaths from this cause from the 5000 to 10,000 usually recorded in a year to no less than 112,329 in the year under notice, the corresponding death-rate being equal to 3129 per million living. In addition to this the epidemic led to a large increase in the loss of life assigned to diseases of the lungs, including tuberculosis. The total deaths attributable to influenza have been estimated to number 132,000. Owing to the exceptional importance of this outbreak and to its continuance until the following spring, it has been dealt with as a whole in a special report now in preparation.

Tuberculosis in its various forms accounted for 58,073 deaths, or 2139 more than those so classified in the previous year. Of these, 1369 were deaths of non-civilians. The mortality among the civilian population amounted to 1694 per million, a figure in excess of the total mortality recorded for any year since 1904. The increase of mortality was probably due to the epidemic of influenza, had it not been for which tuberculous mortality in the year under notice would probably have shown some reduction on that of 1917. The mortality from influenza among sufferers from phthisis is known to have greatly exceeded that of the general community. Notification has not enabled us to do more than estimate the number of the phthisical population, but if the average duration of the disease be taken at about three years there should be about 60,000 female sufferers in England and Wales. The remarkable increase in deaths from tuberculosis in lunatic asylums has been continued throughout 1918, when the fatal cases amounted to 5605, against 4189 in the previous year, and an average of 1800 in the three years 1912-14. This increase has occurred notwithstanding a decline in the number of inmates. A committee which investigated the causes of increased mortality in asylums ascribed the principal share of the increase to reduction in quantity and deterioration in quality of food (particularly flour). Other considerations mentioned as of secondary importance were deterioration of the asylum staffs and want of space for isolation, owing to the evacuation of some asylum buildings for war purposes, and consequent congestion of the remainder. The increase of asylum mortality is considerably greater among the male than among the female patients, a fact which seems to point to deficiency of staff as an important cause, because the demands upon the female staff for special war service would naturally be less than upon the male.

Cancer mortality, if stated in the form of an ordinary crude death-rate, was higher in 1918 than in any other year, but if comparison be made by means of standard rates which allow for the present abnormal age constitution of the male civilian population, there will be seen to have been an appreciable decrease from the previous year's record. Standardisation fails to eliminate entirely the fictitious increase due to the exclusion from the population in war years of a large number of men furnishing very few deaths from cancer. An attempt at a fuller correction, on this account, shows that the standardised cancer mortality of 1918 was probably lower than that of 1911-14 also.

The successive reports from 1915 onwards show how seriously the efforts of the department for the improvement of the national statistics have been hindered by the late war. In our notice¹ of the vital statistics for 1917, shortly after the appearance of the official report, we commented on the difficulties encountered by the Central Office since the outbreak of hostilities, with especial reference to the measures successfully employed for their removal. The present report covers ground which is in some degree common to each of the three preceding. As a conspicuous instance of this, reference may be made to the serious disturbance of

¹ See THE LANCET, June 24th, 1919, p. 1034.

the population directly caused by enlistment for foreign service, in consequence of which there has been derangement of the birth and death ratios when contrasted with those of peace times. After more than five years of war and the aftermath of war it may surely be hoped that the former valuable achievements of the National Statistical Bureau will shortly be renewed. In reviewing the vital statistics of the several years since the outbreak of hostilities Dr. T. H. C. Stevenson has discussed very fully the difficulties of estimating populations, both for the whole of England and Wales and for its various subdivisions. These difficulties have been greatly increased by the war, which has resulted in rendering the methods relied on in normal times useless for the purpose. He has also described in detail the modifications of method resorted to from time to time in framing the population estimates. Returning to the subject on the present occasion, Dr. Stevenson again refers to the independent sources from which the civilian populations of separate localities are derived. These are (1) the National Register, of which a count was made for the purpose in the middle of 1918, and (2) the returns made under the rationing of food scheme. For various reasons neither of these enumerations, devised, as they must have been, for other purposes, can be considered wholly satisfactory from the statistical point of view. It is believed, however, that the food returns have improved with the successive issues of coupons, and for this reason these have chiefly been relied on for 1918, the National Register count being used as a check in certain cases of special difficulty. The results thus obtained are certainly superior to any that could have been prepared in the Central Office by dependence upon the methods formerly employed in the absence of these exceptional sources of information. The changes due to war have been so great that these methods, unreliable even in peace time, would have been practically worthless. The food-rationing returns of local populations unfortunately afford no information on which estimates can be based for subdividing these populations by sex and age. Moreover, inasmuch as the methods upon which they have depended in the past have been rendered useless by the migration attending the war, these estimates cannot be prepared until the census of 1921 is available for the purpose. Their absence has again necessitated the omission or substantial modification of many of the tables usually appearing in these reports.

It should be remembered that throughout this Report the death-rates of males in 1918 are invariably based upon civilian deaths and civilian population. This is necessary, both because of the impossibility of ascertaining the average military population of each district and because experience has shown that under the system of transferring deaths to the area of previous residence civilian deaths alone can in war time be tabulated for local areas.

Mr. Arthur H. Sandiland, late registrar to the Islington Tuberculosis Dispensary, died on July 7th while being conveyed to the Royal Free Hospital in a motor-omnibus in which he had been taken suddenly ill. Mr. Sandiland, who was 72 years of age, received his medical education at St. Bartholomew's Hospital and qualified L.R.C.P. Lond., M.R.C.S. Eng. in 1869.

HOSPITAL SUNDAY FUND.—The following church collections, &c., have been received at the Mansion House up to June 27th.

£670: St. Columba's (Church of Scotland), Pont-street; £394: St. James, Piccadilly; £370: Holy Trinity, Sloane-street; £335: Christ Church, Lancaster Gate; £314: St. Michael's, Cornhill; £206: St. Alphage, London Wall, with St. Mary, Aldermanbury, and Westminster Chapel, Buckingham Gate; £175: St. Jude's, South Kensington; £174: Brixton Independent Church; £150: St. Anne's, Stamford-hill, and Whitechapel Primitive Methodist Mission; £147: St. Andrew's, Lambeth; £145: Great Stanmore Parish Church; £139: St. Mary's, Islington; £134: St. Anne's, Soho; £128: St. Jude's, Midway Park; £127: Immaculate Conception, Farn-street; £123: All Saints, Margaret-street; £116: St. Philip's, Kensington, and St. Peter's, Belsize Park; £104: Christ Church, Gipsy-hill, and St. Luke's, Redcliffe-square; £103: St. Bartholomew's, Sydenham; £102: Temple Church; £101: Christ Church, Westminster.

The following donations are also announced:—
£500: National Bank of India, Ltd.; £300: Sir John Ellerman, Bt.; £200: Mr. Alexander Miller; £105: Mr. W. H. Cullen; £100: Messrs. Hunt, Leuchars, and Hepburn.

THE CONSULTATIVE COUNCIL OF MEDICAL AND ALLIED SERVICES:

A DISCUSSION AT BRISTOL.

A MEETING of the Bath and Bristol Branch of the British Medical Association was held at Bristol on July 9th, and was inaugurated by a luncheon given at the Royal West of England Academy, Bristol, by Dr. P. Watson-Williams, President of the Branch.

Dr. Watson-Williams's Luncheon.

Lord Dawson of Penn was the principal guest, while the Lord Mayor of Bristol and the Lord Mayor of Cardiff were also present, as well as prominent representatives of medical interests of all sorts.

Dr. WATSON-WILLIAMS, in proposing the toast of the Consultative Council, attributed the movement culminating in the creation of a Ministry of Health to the efforts for 50 years of the British Medical Association, and in the first instance to Dr. Rumsey, of Cheltenham. He said that the Report of the Consultative Council supported rather than supplanted existing organisation, the object being not the effacement of the present provisions, but their coördination and evolution. He considered that the Council constituted an organised nexus between the Ministry and the medical profession, and might become an official channel by which the profession could give direct expression of its views to the Ministry. But it was certainly of the utmost importance that the medical profession should have some voice in the recommendation of suitable members of the Council if the Council was to exercise its functions in the most useful manner.

Lord DAWSON said that it was by no means a usual procedure for reports made to Ministers to be published for the open criticism of the public and of the section most concerned. That such a course was followed in this instance was due to the liberal-mindedness of Dr. Addison. After congratulating the West Country upon its reputation for the care of the sick, he said that a new chapter was now opening in the story of the hospitals of this country, and that the West of England was once more in the forefront; for already, in the county of Gloucester, a scheme had been laid down by Dr. Middleton Martin, forecasting the Report of the Consultative Council. Under this scheme general practitioners were brought into relation with primary hospitals, which were staffed by themselves, and these primary hospitals were linked up with secondary hospitals in the larger towns. Such a scheme, although it had not yet reached the stage of fruition, showed that here in the West the responsible people were thinking in terms of 1920.

Passing on to a general exposition of the report of the Consultative Council, Lord Dawson said that the provision for the health of the people in hospitals or otherwise was demonstrably inadequate. It needed not to be swept away, but to be expanded and adjusted. Hospitals were inadequate because the population had grown more rapidly than they had done; also because the basis on which hospitals had been distributed was not determined by the needs of local populations, but by the chance existence of public spirit and benevolence in the district; and yet again because recent progress in medicine demanded increased institutional treatment which the present hospital system was not elastic enough to supply. It was not a case merely of providing more hospitals, but of the careful grading and linkage of hospitals. Another reason why change was imperative was to be found in the awakening of the public conscience on health matters; people had now a positive instead of merely a negative conception of health, and there was a sharper demand for preventive measures and for dealing with incipient disease. The general practitioner of the future would require to be more closely identified with preventive medicine and to have access to necessary equipment. The present state of the hospitals proved how completely they had been outgrown. Many hospitals had waiting lists hundreds deep, and this was the more lamentable because these waiting lists comprised the people in whom disease was in its early stages, and whom it was most important to cure from the point of view of the community. The disability from sickness was a great weight upon the nation. In 1916 sickness benefit in England for men alone amounted to nearly 3½ millions of money, representing 6,800,000 weeks of sickness and consequent withdrawal from employment. The average annual loss due to sickness and disablement in the case of both sexes for the years 1914-16 worked out at 270,000 years, and in these estimates all light sickness (of shorter duration than four days) was excluded, as well as all maternity cases and cases in sanatoriums. If

an adequate health organisation existed, these figures should at least be halved. The criticism had been levelled at the report of the Council that it would entail a huge expenditure on medical services at a time when the country was impoverished, but he and his colleagues recognised that great wars must be followed by strict economy, and that however desirable certain changes might be, it was necessary to wait for the full development and to do the best that could be done in the meantime. All that was asked at the moment was that stock be taken of the position, that a reasonable review be made of what existed at present compared with what should exist, and that a scheme be devised in sufficient outline to reveal the plan according to which the health organisation of the future should shape. There was already a patchwork of medical services—tuberculosis, venereal, and so on—which had come, each in response to an urgent demand, and not as the result of any ordered policy. The time had arrived to consider the whole position and decide upon the lines of development, after which they should set to work cautiously and tentatively to build up the fabric of a medical organisation which should properly fit national needs. The Consultative Council was quite prepared to find that such a fabric could only be set up step by step. Certain principles must be laid down, but they must be principles which should be capable of some immediate applications, and he hoped that one such application might be made in Bristol.

The burden of the report was simply this: the provision of fabric and equipment, together with freedom of action for doctor and patient. It was fully recognised that the bulk of patients would be seen as heretofore in their own homes or at the practitioners' surgeries; but in each district there should be set up an institution which would contain the necessary equipment for the practitioner to complete and accelerate his work. The primary health centre would be a general practitioner clinic; only in the secondary health centre would the patient be transferred from the care of his own medical attendant. The primary centre was the most important part of the scheme at the moment. The secondary hospitals already existed; the primary hospitals were only represented at present by a few cottage hospitals inadequately equipped. The pecuniary relation between doctor and patient would remain undisturbed by the proper development of primary centres. The laity and the medical profession should discuss this matter together in view of the tendency for certain infirmaries to be handed over to the municipalities. A municipalised service was one step forward to the nationalisation of medicine, and that would be a disaster alike to the medical profession and to the public. This was not a time for criticism on the ground that the scheme would cost so many millions. What it was ultimately going to cost was of small importance. In 1870 many people might have been frightened had they been told that education would cost the country annually 33½ millions—which was the figure it reached in 1918—but no one at this time of day ventured to urge that less should be spent. The heavy expenditure which some forecasted on these new health arrangements would not come at once, and when it did come it would be more than met by the corresponding gain in national health and efficiency. He hoped that in the West Country, with its traditional munificence in hospital matters, two primary health centres might be set up as an experiment, one of them in the town and the other in the country. They would be of great service to their locality; they would relieve the strain on existing institutions, and they would have the high value of an example to the whole nation.

THE LORD MAYOR OF BRISTOL, who proposed the health of representatives from neighbouring towns and counties, expressed his satisfaction that no great expenditure was immediately demanded, for in his position as head of a great municipality he was committed already to raising large sums of money for housing and other purposes. The full scheme was estimated to cost 150 millions a year, of which 90 millions would be for medical men, and 60 millions for nurses and establishment charges. His advice was to hasten slowly.

THE LORD MAYOR OF CARDIFF, who responded to the toast, was less pessimistic than his brother magistrate. He had no fears with regard to the eventual finance of the scheme. Once the real meaning of the scheme was understood by the people in the industrial areas—particularly that it was not intended to interfere with the freedom of relationship between doctor and patient—he was sure that they would lend a willing hand to make it a success. He hoped that the scheme would not be worked by existing local authorities; a separate *ad hoc* body should be created in the various districts. He looked to the scheme to mature in 20 years, by which time he believed the results would be magnificent.

The proceedings closed after the health of Dr. Watson-Williams had been drunk on the proposition of Mr. H. H. WILLS, President of the Bristol Royal Infirmary.

The Meeting of the Bath and Bristol Branch.

Following upon the luncheon, a meeting of the Bath and Bristol Branch was held, Dr. WATSON-WILLIAMS presiding.

Lord Dawson said that his desire in meeting the branch was to elicit criticism and opinion. The medical profession had now an opportunity such as it had never enjoyed before in its history. It had been an individualistic calling and had shown a certain aloofness from public questions. But there had been growing up in recent years a steadily increasing relationship between the doctor and the community. It was for the profession now to give a lead to the nation on health matters. The public, in whose eyes the profession had gained a heightened esteem owing to the war, was prepared to listen to constructive proposals. The interim report of the Consultative Council was an attempt to systematise medical services. It endeavoured to make the preventive and curative sides of medicine meet in the general practitioner. The general practitioner must be looked upon more and more as the guide in matters of health to the residents of his district. The director of the communal clinic or primary health centre should be a man whose practice was in the district; his post should be a part-time one, paid on a time basis. This was the alternative to a whole-time salaried service. Training would be required for such a post, and this simply meant an extension of post-graduate instruction. Lord Dawson went on to point out that the methods of investigation and treatment of disease were becoming ever more complex. The more that knowledge advanced, the more was the insufficiency of the general practitioner's equipment demonstrated. Nothing astonished him more as a consultant than the excellent work which was done by men under poor conditions. One of the vital parts of the organisation now foreshadowed was the full participation of the general practitioner in the communal equipment available at the health centre. The ideal primary health centre would have a certain number of rooms available for the examination of patients; there would be X ray provision, particularly for screen examinations, also facilities for blood testing, and so on. The administration would charge a flat rate for the use of the equipment; the pecuniary relation between doctor and patient would remain undisturbed. In the larger centres there might be arrangements for physiotherapy and massage at reasonable charges. There would also be wards, including private wards for patients who could afford to pay for them, though the treatment would be the same, of course, in the private as in the general ward. The various communal clinics which were already growing up would be brought under the wing of the primary health centre. The primary health centre had then to be correlated with the secondary health centre in the shape of the existing hospital in the large town. Here those consultative services, which were envisaged as part of the National Insurance scheme, but were held up by the war, would be available. The consultants would serve on a part-time basis and at scheduled rates, paid by the State. This would attract young consultants, to whom a certain assured income, however small, was a great help in the early days of practice. A great deal depended upon the maintenance of intellectual traffic between the primary and secondary health centres. The cost of the scheme had figured largely in the debate at the recent Representative Meeting, but it was not intended to pepper England with primary health centres right away. He would be content to see a dozen such centres established within a reasonable time.

Dr. J. MIDDLETON MARTIN (M.O.H., Gloucestershire) gave an account of the experiment in his county. He said that while it was more or less a simple matter to provide in the towns the special services now required, the matter was more complicated in country districts. In Bristol, for example, there were 13,000 persons to the square mile, while in Gloucestershire, not one of the most sparsely populated counties, there were only 278. It was out of the question to provide special services adequately for a scattered population on the same lines as one could do it for a compact population. Then the question of a general practitioner came in; it was going to be a disastrous thing for the medical profession if continually certain branches of work were taken away from the general practitioner, and this would not be a good thing for the community either, because the preventive side of public health required a knowledge of the circumstances of the local community and the homes of the people; and who possessed this knowledge to the same extent as the general practitioner? Therefore his aim in Gloucestershire had been to bring the general practitioner into relation with what Lord Dawson's report called primary health centres. The attempt was made to develop the present communal services into one recognised centre where the local practitioners could deal with the cases. The services in question were mainly out-patient services, but a certain number of beds were also wanted. He was now engaged in trying to discover the most suitable

places for such out-stations. The stations would be of a very simple character, but such as to lend themselves to development. The direction of these centres was an important consideration. There had been complaint in the past that medical schemes were under lay direction. Medical matters were so technical that there must be medical direction of such services, and from a plan already in operation in Cheltenham he had conceived the idea of setting up a medical advisory committee, composed, in the case of Gloucestershire, of the general practitioners in charge of the out-stations and the consultants at the hospitals. All medical matters would be referred to that committee, which would be the governing body in medical matters. He did not suggest that all difficulties had been overcome, but sufficient advance had been made to prove the practicability of the idea. As for finance, the complete scheme was not too expensive to be carried out at the present time. The money had been found in Gloucestershire by pooling the sums available for the separate schemes, and in this way sufficient money was found without increasing the estimates.

Dr. MARCUS MILLIGAN (Bath) suggested that in each area, in association with the scheme, there should be formed a local guild of preventive medicine or guild of health, a body whose function would be the collective study of all health matters, as well as health propaganda. All the general practitioners and consultants in the area would be included in the guild, as well as such persons as certifying factory surgeons, the public analyst, some representative of the education authority, members of the dental profession, and also veterinary surgeons, the last in view of the way in which animals communicated disease.

Dr. H. C. BRISTOWE (Wrighton, Somerset) spoke of the difficulties in the more sparsely populated rural areas, where the means of communication were mostly not main roads or railways but winding lanes, and the population scattered in small villages, none of them with more than 800 inhabitants, with hamlets and solitary houses in between. Practitioners engaged in work in these districts had not time to go a further five or ten miles to attend the primary health centres in a neighbouring town or larger village. He pleaded for smaller centres, less ambitiously equipped, and distributed more frequently in the sparsely populated districts.

Dr. R. H. NORGATE (Bristol) asked what provision it was proposed to make for chronic cases, such as spinal disease. They all knew in private practice that there were a number of people who could not earn their living and were a burden on their families. What was it proposed to do, if anything, for these?

Dr. WILLIAM GORDON (Exeter) said that his first acquaintance with the scheme inclined him to destructive criticism, but Lord Dawson by his advocacy and Dr. Middleton Martin by his practical experiment had established a case for the primary centre. They were countering the tendency to set up whole-time services, and were restoring to the general practitioner what he ought not to have lost; that was so much to the good. But the scheme as it stood on paper suggested that there was going to be undue interference from the secondary and teaching centres with the general practitioner, and this he would deprecate. Mutual counsel and help there should be, but as little interference as possible. He hoped also that it would not be laid down that those in charge of these centres should keep elaborate routine records. This would interfere with the time available for the care of the patient. Whatever records were kept should be of the simplest kind. Then he thought that the recurring expression "team-work" was unfortunate. The profession in England had been made great by reason of its individuality, and the individualism of English medicine should be most sedulously preserved. After all, the highest human achievements were individual, not the work of a team. The speaker uttered a threefold warning. First, against hustling; secondly, against too much attention to what Labour people were thinking, as Labour showed a disposition to meddle in subjects which it did not understand; thirdly, against the German tradition which magnified equipment at the expense of genius.

Dr. G. T. MYLES (Clifton), while admiring the report as a whole, thought that to express unqualified approval at this stage might mean the handing over by the profession of a blank cheque to the State. The success of the scheme depended entirely on the wholehearted support of every section of the profession, and if very much new work was put upon the profession an adequate remuneration must be given; with this subject the report did not deal. He thought that it would be possible to erect through this scheme with its primary centres nothing less than a whole-time service State-controlled.

Dr. NEWMAN NEILD (Clifton) said that in all schemes for the health of the people there were two possible methods. One was to let the Government put down the money first; certainly no great improvement in the health of the community had ever been gained by that method. The other was to start by stimulating the enthusiasm of the profession,

so that it did the pioneer work and left the matter of payment until later; and that was the way in which advance in medicine had always been gained. He did not think the scheme would mean any hardship for the general practitioner; the only people who need complain, so far as he could see, were the consultants. What some of them were afraid of was that certain lines of research and methods of treatment would be forced upon them, whereby a free and untrammelled individualism would be lost.

Dr. L. S. LUCKHAM (Salisbury) said that he came from a city of some 25,000 people, with a large country district contiguous, the latter containing villages of 200 or 300 inhabitants. It was very difficult to establish primary health centres which would meet the case of such a district. The most valuable thing would be to combine the county hospital with the primary centre, the two working together. He rather thought it had been forgotten that a great deal of hospital accommodation was taken up because homes were not suitable even for minor cases of illness.

Dr. E. J. MACLEAN (Cardiff), speaking as a member of the Welsh Consultative Council, said that there appeared to be some misapprehension with regard to the status of the Councils. They were advisory to the Minister and in no sense intended to replace the organised bodies of the profession. There was nothing in these councils which would interfere with the status of the British Medical Association. So far from having its functions replaced or undermined, the Association should be strengthened and made still more representative. The movement to bring the profession under State control was very active. Many people felt that in view of the administrative power which the profession possessed some such control was necessary, and the maximum amount of it would be gained through a State medical service. Turning to the reports of the English and Welsh Consultative Councils, he said that if they did in large part agree it was not the result of collusion, for the Welsh Council had deliberately kept away from the English body in order that the problems might be approached with an unbiased mind. The Welsh Council was composed not only of members of the medical profession but of representatives of various public authorities, whose criticism was available on points as they arose. The Principality was compact, and thus visits could be paid to representative areas—that is, purely rural areas, mixed areas, and densely populated industrial areas—and certain principles had been applied as the result of their acquaintance with those three sets of conditions. The present stage, he thought, was not one for much criticism, but there would come a time when very critical and contentious issues would have to be faced.

Dr. C. E. S. FLEMING (Bradford-on-Avon) said that the profession had had placed within its grasp what it had been fighting for for years—namely, the opportunity to do its work properly. But there was a fear that the independence of the individual practitioner was threatened, and, while independence from every sort of control was impossible, it should be limited to intra-professional control. With regard to the relation of the general practitioner to preventive medicine, he would like to see every medical man given more powers approximating to those of a medical officer of health—powers to advise, report, and suggest—because no man was better able to make an effective medical officer of health than the general practitioner. The primary health centre was the ordinary development of institutions and work already in existence.

The PRESIDENT, in closing the discussion, conveyed to Lord Dawson the thanks of the branch, and said that the views expressed might be summed up in the view that the profession feared organisation being imposed upon it from without, and believed that the best way to meet the situation was to co-ordinate its work and prove its statesmanship.

Lord DAWSON, in reply, considered that the Consultative Council in no way usurped the present means of communication of the views of the profession. At the same time it did offer a nexus between the profession and the Minister. The Council, although nominated by the Minister, was absolutely independent. There seemed to be a fear amongst some speakers of the danger of State service or State control. But where some had pointed to individualism he saw only intellectual anarchy. If by individualism was meant absence of all control that was something which would not be good for the profession, and something which the community was not in the least likely to concede. He had to remind them again that State service was now coming. Various instalments of State service had already been set up. The report of the Council was not making for State service; it was the sole alternative. He agreed with what had been said about the dangers of bureaucratic control, but he had found no responsible person in the Government or Ministry of Health eager for such control. There would be no cast-iron health service organised from Whitehall. The Ministry of Health would be the inspirer, controller, and co-ordinator—that was all. He took it that subject to certain broad principles there would be considerable difference of detail in the various areas. Whatever the constitution of the local

health authority, they claimed that the medical profession as such must be represented upon it. A few broad-minded medical men would have an influence on such an authority far beyond their numbers. The majority of members must be elective, but in the co-opted minority the profession claimed to have a strong voice. He agreed that the profession must be adequately remunerated, but it would be a mistake to let it be supposed that pecuniary considerations occupied all their thoughts. He believed the general effect of a properly organised system would be to enhance the pecuniary position of the men who practised under it, and he did not believe that in most instances it would increase their work, although it would add enormously to the interest of the work.

Lord Dawson concluded by sympathising with the criticism which had come from sparsely populated areas, and said that the question of subcentres, and also of ambulances, had been considered by the Council, but had not yet reached the stage of definite proposals, in a report which was an interim document capable of indefinite adaptability. He deprecated the remarks of Dr. Gordon on the subject of Labour, as most intelligent views had been forthcoming from that quarter, and if a broad-minded scheme were hammered out he was sure that Labour would offer most unprejudiced assistance.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Influenza Complicating the Ear and Upper Air Passages.

IN the spring of this year severe influenza epidemics have occurred in several parts of Transylvania, the numbers of cases even surpassing those of 1918. Dr. Muntean has studied the complications of ear and upper air passages and has just published a concise report. He considers first the relation of influenza to the ear, and states that it may affect either the inner ear, of the diseases of which little is known, or the middle ear, involving either the drum membrane alone or the entire middle ear—as first described by Dr. W. Hitschler in America. The disease differs from the ordinary otitis media in that in the early stages of the condition there is a marked tendency to hæmorrhage, which may be observed as punctate or diffuse ecchymoses on the tympanic membrane, or as bloody vesicles raised from its surface, sometimes extending beyond the membrane itself, and involving the postero-superior wall of the external auditory meatus. The pain is more severe and is more likely to be present on pressure over the mastoid, and the symptoms of tinnitus, deafness, and discharge are intensified. The mastoid is much more likely to be involved than in other conditions, and the external attic is often the subject of purulent inflammation. The diagnosis between this condition and severe simple acute inflammation is very difficult; the prognosis is less good, and the tendency to chronicity greater than in the latter. In the upper air passages, in addition to the usual catarrhal signs, there are frequently whitish-grey patches, due to necrosis, on the larynx and trachea. Hæmorrhage, in the shape of epistaxis or hæmorrhagic laryngitis, oedema of the larynx and pharynx, and abscesses of the larynx and thyroid gland have also been observed. The recurrent laryngeal nerve is frequently affected, and paresis of the soft palate is among the nervous symptoms. Dr. Muntean refers in his report to the tendency to sinus diseases in these cases, and also to the fact that, though many cases recover, there are a certain number which result either in chronic sinusitis or in a transmission of the infective process to the orbital or cranial cavities, with occasional fatal termination. A meningitis can be caused by an acute empyema of an accessory sinus; too often the ætiology is unsuspected, and it is forgotten that such cases are likely to occur in acute exacerbations of a chronic sinusitis brought about by some infective process such as influenza.

A Case of Chlorate of Potash Poisoning.

Dr. Papp reports an interesting case of poisoning from chlorate of potash. The patient, a woman, aged

32 years, purchased from a druggist a bottle containing 60 g. of chlorate of potash. Though the printed directions were to dissolve 1 tablespoonful in 1 kg. of water, the patient used the entire 60 g., and occasionally swallowed some of the solution. After finishing the bottle the patient complained of itching, and after four days her thighs, legs, ankles, forearms, wrists, and trunk were seen to be covered with innumerable reddish macules. There were also numerous petechiæ. There was no nausea, diarrhoea, or headache. The patient made a slow but uneventful recovery.

Radium in Cancerous Growths.

Dr. Offner recently showed five patients before the Medical Society of Bucharest, two having a cancerous ulcer at the inner angle of the right eye. The treatment began February, 1919; weekly sittings; duration one hour. The bromide of radium was used; improvement was noticed in both cases after every application. For some reason one of the patients discontinued treatment after six weeks, with the result that the condition became worse, and the edges of the ulcer, which were in a fair way of cicatrization, reopened. Treatment was resumed, with the result that the ulcer, which had obstinately resisted treatment for five years, now healed completely. The third case was that of a cancer of the lip; treatment with radium resulted in a marked improvement. The fourth case was a cancer of the penis; result unsatisfactory on account of repeated attacks of pneumonia in an aged patient. The fifth case was that of a cancer of the breast, for which the patient was operated on twice—nine and three years ago. In this case applications were made three times a week, and after 26 sittings the tumour seems to have disappeared. The patient has regained perfect control of the shoulder-joint; the tumour was located under left clavicle.

Nervous Debility among the Working-classes.

Excellent facilities for the study of this subject are presented in one of the largest workmen's sickness insurance clubs, and Dr. Oltmann and Dr. Meer have recently made observations on the question. It was formerly believed that nervous debility was relatively rare among this class, but this conception must now be revised. The greater incidence may, of course, be due to the fact that the lower classes are now under more systematic medical observation—at least in Transylvania—than formerly, but the previous observers are rather inclined to the belief that it is produced by our changed social conditions. The work itself and the conditions under which it is performed are different, and are characterised either by greater excitement or by extreme monotony. The struggle for existence often induces longer hours of work, and another important rôle is played by the disparity which exists between the intellectual equipment of the workmen, especially in larger cities, and the small claim made thereon by their work. Thus the typesetters, often fairly well educated, pursue an occupation which is not only fatiguing but monotonous. Among workmen where manual labour is of such a nature as to be productive of some degree of enjoyment neurasthenic conditions are rarely to be found. The majority of cases were noted between 25 and 45 years of age—the age of introspection.

Typhoid Fever Epidemic in Children in Bessarabia.

In September, 1919, a localised typhoid fever epidemic broke out in three or four districts of Bessarabia, and Dr. Slivensky publishes now some remarks on the 210 cases observed by him. He says that his cases seemed to show a relation between vomiting and hæmorrhage; especially in cases in which vomiting existed from the first was hæmorrhage apt to occur. The appearance of the stools in very young children was not so characteristic as in adults, though in older children pea-soup stools often occurred. A preliminary constipation was shown to have no evil significance, as has sometimes been claimed. Rose spots occurred in 54 per cent. of all cases, and herpes in eight cases, though several of these had complications. The average duration of the fever was 14½ days, a much

shorter period than is usual in the adult. The usual parallelism between the pulse and the temperature was not present in very young children. The characteristic leucopenia was present, and the Widal reaction occurred in nearly all cases where it was tried sufficiently late. Relapses in children, especially in girls, were more frequent than in adults. The mortality in Dr. Slivensky's cases was 9·6 per cent., and was much more frequent in relapses than in original attacks. Bad hygienic conditions conducted generally to fatality.

Plague Epidemic in Constantinople.

On account of the great number of cases of plague in Constantinople the Bucharest Government has officially declared the disease epidemic in Constantinople. Passenger traffic and goods transport can be passed only through the Sulina Port, where every person arriving has to be quarantined for eight days.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Medical Strikes in Sickness Insurance Clubs.

THE economic fight between the profession and the sick clubs, or Krankenkassen, as our official compulsory panel clubs are termed, is going on constantly in spite of the nearly uniform outcome—victory of the profession. The clubs are, as a rule, not willing to give in voluntarily, but after a while they are compelled to do so. In a recent protracted and obstinate dispute in Salzburg the whole profession refused to treat the panel patients under the whole conditions; after five weeks the managing board of the Krankenkassa accepted the conditions of the profession—that is, 100 per cent. increase of rate of payment per visit, not per head as hitherto, also payment of rent and for mileage. During the dispute the patients of the club were treated on the same lines as private patients, and the club had to refund to its members their expenditure, which proved nearly ruinous to its funds. The outcome of this "strike" served not only as a stimulus to the profession in other districts, but also helped materially in the negotiations between the Government and the profession going on at present. It is intended to solve the question of adequate payment of medical work, having regard to the legitimate demands of the working-class. As the income of the latter has risen much above that of brain workers, the doctors as brain workers endeavour to admit only persons to the sick clubs whose income does not exceed a certain sum. Otherwise, private practice would actually disappear. It is, therefore, very important that the Government should learn by such a demonstration that the profession is capable of using its power if required.

Gratuitous Treatment in Out-patients' Departments.

A serious problem has been attacked by the Medical Organisation Committee of Vienna at a meeting dealing with the organisation of general and special hospitals. Owing to the enormously increased cost of running the hospitals, the treatment of other but really poor patients constitutes a serious loss of public money. Also, the profession loses large sums in the shape of fees by the fact that a large number of patients capable of paying are still directed by their medical advisers to hospitals, instead of being sent to private specialists. In an appeal to all practitioners, these facts are made clear and they are requested to abstain from helping abuse. At the same time they are furnished with a complete list of recognised specialists, so that they can select the man they deem best fit for their purpose. On the other hand, all specialists attending or controlling the out-patient departments are requested to be most careful in extending their help only to such patients as can satisfy them as to their real poverty. Stress is laid on the fact that all persons in public or municipal service should be excluded from gratuitous treatment in hospitals, as these corporations are bound to obtain medical help for their officials. Payment from out-patients should be accepted only in special instances, and only at the same rates as are demanded in private cases.

The appeal mentioned above is being sent to all country doctors as well as to the directors of the minor hospitals of the provinces, and it is hoped that reasonable self-interest, as well as professional spirit, will bring about the required uniformity of action.

Dangerous Dyes in Black Cotton.

At a recent meeting of the Medical Society of Vienna Dr. Sachs demonstrated an excised forefinger (index) of a woman who had injured it some time ago with a thread of black cotton imported from Italy. Soon after this slight injury the finger became sore, boils and bullæ appeared, and ulceration ensued in spite of regular treatment. Necrosis followed, and the finger had to be excised. Examinations by bacteriologists and chemical experts showed that micro-organisms were not the cause of the pathological changes (only staphylococci were found), but that the chemical dye used in the process of manufacturing the cotton was responsible. The dye is known as "iceblack," a coal-tar dye; its necrosing effect was noticed some time ago, and is similar to the evil effects of the dye, with which the so-called ink pencil is charged. Special precautions in the process of colouring of industrial articles are therefore being urgently advocated.

Vienna, July 9th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

Anti-hookworm Campaign.

THE Bengal Government have issued a review of the work of the anti-hookworm campaign in Bengal. Inquiries having shown the prevalence of hookworm infestation among the people of Bengal, the Government, towards the end of 1918, called together a conference of the Sanitary Board, members of District Boards, and representatives of jute and coal industries and other interests, and invited their advice as to the measures to be taken to fight against the disease. In accordance with the recommendations of the conference, Government appointed three special officers with subordinate staff to supervise and direct all operations. A year has now passed since their appointment; work was at first impeded by ignorant suspicion on the part of the natives, who imagined that it was part of the insidious scheme connected with the Rowlett Act, and that persons suffering from disease would be discharged. This prejudice was gradually overcome and a high ratio of infestation has been detected, the percentage in one month being 75 in one mill and 92 in another. In another mill, of skilled artisans who mostly wore boots, 35 per cent. were found to be infected. During the first four months of this year 3112 persons were examined and 8·5 per cent. were found infected. Arrangements have now been made by the Anglo-Indian Jute Mill for work to be carried on by a special officer. Training has been given to subassistant surgeons of the Bengal-Nagpur Railway and the ordnance factories at Cossipur, Ishapur, and Dum Dum. The chief medical officer of the Eastern Bengal Railway is arranging for all sub-assistant surgeons in railway hospitals to be trained. The aim from the first has been to utilise Government staffs for the work and for training the local staff, so that the managing authorities of different concerns may take up anti-hookworm work themselves. It is impossible for Government to open laboratories at all the centres where they are needed, so those who will benefit most provide them at their own expense. In order to diffuse a knowledge of the disease, charts have been supplied to schools, for it has been realised that propaganda is the only way to make the people realise the seriousness of the disease. Persons suffering from hookworm, if willing to submit themselves, may be treated by trained assistant surgeons. Nearly a hundred different lantern slides illustrating the life-history of the hookworm and various aspects of preventive work have been prepared, and have been issued to various centres of work and to local authorities and

others interested in the campaign. The extension of the movement has, however, been impeded by difficulties in obtaining supplies of microscopes and other apparatus.

The Housing Problem in Calcutta.

At present the chief obstacle in the expansion of Calcutta is the difficulty experienced by building societies and companies in obtaining land and securing a firm title. It is evident that private enterprise is willing to take up the matter provided land can be obtained, so Government have decided to acquire land under the Land Acquisition Act on the behalf and at the expense of the companies.

The Leper Problem.

A gratifying feature of the report of the Mission to Lepers is the announcement of substantial subscriptions from Indian ladies and gentlemen. The need for asylums is great, as there are 150,000 lepers. Hitherto the funds have all come from England, but efforts to obtain money from the Indian public have met with great success recently. The whole population is concerned in the matter, as the pauper lepers are a serious menace to the community. This menace will be met if the Bill to amend the Leper Act becomes law and is efficiently administered.

Indian Hospital Corps.

With the approval of the Secretary of State an Indian Hospital Corps has been formed. It will combine with the Army Bearer Corps, the Army Hospital Corps, and all subordinate personnel of Indian station hospitals. The corps will consist of 10 divisions, corresponding to the divisions in India and Burma, the requirements of the frontier coming from No. 1 Company, those of Aden from No. 6 Company. Each company so formed will be administered by the D.D.M.S. or A.D.M.S. of the division concerned, and will be under the immediate command of an officer of the medical services, who for purposes of discipline and finance will be the commanding officer of the company.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been made:—Surgeon Commanders: E. C. Sawdy, to *Victory*, for Royal Naval Hospital, Portland; G. Gibson, to *Indus*, and K. H. Hole, to *Royal Arthur*; H. J. Chater and R. W. B. Hall, to *President*, additional, for temporary service at Medical Dept. and as assistants to M.D.G.; and E. R. Townsend, to *Dolphin*.

Surg. Rear-Admirals G. T. Broatch, W. J. Colborne, and J. H. Stenhouse are placed on the Retired List at their own request. Surg. Capt. G. T. Collingwood to be Surgeon Rear-Admiral.

ROYAL ARMY MEDICAL CORPS.

Major W. F. H. Vaughan is placed temporarily on half-pay on account of ill-health contracted on active service.

To be Captains:—Capt. C. C. G. Gibson (late R.A.M.C.), Temp. Capt. C. J. R. Hay, from Special Reserve. Captains, from Special Reserve: C. Armstrong, W. H. Dye, N. Cameron, J. Cullenan. Temporary Captains: A. W. Dennis, G. Fleming, K. M. Nelson, A. C. Taylor.

H. Cardin, late temporary Captain, to be temporary Captain. Captains, from Special Reserve, to be Lieutenants, and to be temporary Captains: W. I. FitzG. Powell, W. O. Holst.

Capt. D. W. M. Mackenzie, late R.A.M.C., Special Reserve, and Hon. Capt. C. A. Hutchinson to be Lieutenants and to be temporary Captains.

Temp. Hon. Lieut. W. N. Richards to be temporary Honorary Captain.

Officers relinquishing their commissions:—Temp. Capts. (Acting Major) L. J. Spence and A. Fletcher (granted the rank of Major). Temporary Captains retaining the rank of Captain: D. McLaren, J. Buchanan, J. R. Fleming, L. D. Roberts, A. Vella, G. C. Berg, C. R. Worthington, W. L. Johnston, T. H. Edey, G. Taylor, G. O. Hempson, A. B. Coomber, D. J. Stokes, H. A. Whyte-Venables, P. H. Henson.

SPECIAL RESERVE OF OFFICERS.

Capt. P. W. Mathew relinquishes his commission and is granted the rank of Major.

Captains relinquishing their commissions and retaining the rank of Captain: P. N. Cook, W. Burridge, N. D. Ball.

TERRITORIAL FORCE.

Major (Bt. Lieut.-Col.) A. B. Harris resigns his commission and retains his rank, with permission to wear the prescribed uniform.

Capt. P. H. Mitchiner is seconded. Capt. D. J. Scott resigns his commission and is granted the rank of Lieutenant-Colonel.

Capt. C. P. Brentnall, W. B. Keith, and J. R. B. Russell resign their commissions and are granted the rank of Major.

Capt. F. Tooth, C. Hibbert, L. Courtauld, W. T. Torrance, and W. R. H. Heady resign their commissions and retain the rank of Captain.

TERRITORIAL FORCE RESERVE.

Surg. Major W. H. Cheetham (Yeomanry) resigns his commission and retains the rank of Surgeon Major, with permission to wear the prescribed uniform.

Capt. S. E. Whitnall resigns his commission and retains the rank of Captain.

INDIA AND THE INDIAN MEDICAL SERVICE.

Col. P. Carr-White to be Major-General.

Capt. E. G. Kennedy relinquishes the acting rank of Lieutenant-Colonel.

Dr. W. O'Brien Beadon, Principal of the Women's Medical College, Agra, goes on nine months' furlough. During her absence Dr. G. J. C. Campbell, W.M.S., will officiate. The services of Lieut.-Col. G. Tate are temporarily placed at the disposal of the Political and Foreign Department. Major J. G. G. Swan is officiating as Civil Surgeon, Lahore, and acting as Professor of Midwifery at the Medical College, in addition to his own duties. Col. L. J. M. Deas has been posted as Civil Surgeon, Aimer, and Chief Medical Officer in Rajputana. Lieut.-Col. E. L. Perry has been posted to Madras. Major D. P. Gort, Civil Surgeon, Rajshahi, has been allowed privileged leave. Major J. T. Parkinson has been placed on the supernumerary list, but will continue to act as Assistant to the Civil Surgeon, Mussoorie. Lieut. F. W. Mathews, Superintendent, Central Prison, Naini, Allahabad, is appointed Civil Surgeon, vice Major Hogan, Civil Surgeon, placed on the supernumerary list, but will continue to act as Superintendent, Central Prison, Naini, Allahabad. Capt. P. B. Mills has been appointed Civil Surgeon, vice Capt. Robertson, relieved, but will continue to act as Superintendent, Central Prison, Fategarh. Capt. R. Hembell, R.A.M.C., has been appointed to hold Civil Medical Charge of Raniket, vice Lieut.-Col. A. T. I. Lilly, R.A.M.C., in addition to his own duties.

DEATHS IN THE SERVICES.

Inspector-General of Hospitals Sir James Nicholas Dick, K.C.B., R.N., honorary surgeon to the King, at his residence, Beunbridge, Isle of Wight, on July 12th, aged 89. As Assistant Surgeon during the Russian war in 1854-55 he served in the *President*, the flagship of Lord-Admiral Price, and was present at the attacks on Petropavlovsk on August 31st and Sept. 4th, 1854, when he was specially mentioned for his care of the large number of wounded. Later, as surgeon, he served on the West Coast of Africa and as senior medical officer in charge of the naval forces and Indian troops. He was also senior naval medical officer during the Abyssinian war, 1867-68, and for his services was specially promoted to the rank of Fleet-Surgeon (Abyssinian medal). During the Civil War in Spain, when Fleet-Surgeon of the *Lord Warden* flagship, in 1873, he proceeded into Cartagena during the bombardment as a volunteer to assist the wounded, and received from the Admiralty an expression of their high estimation of the zeal, energy, and skill shown by him in the performance of his duties in connexion with the R.N. Hospital, Malta, of which he was the principal officer during the Egyptian campaign, 1882. On the occasion of the celebration of the completion of the fiftieth year of Queen Victoria's reign he received the C.B. and was Director-General of the Medical Department of the Navy from 1888 to 1898. He became a K.C.B. in 1893.

URBAN VITAL STATISTICS.

(Week ended July 10th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had declined from 13·8 to 9·9 in the eight preceding weeks, was again 9·9 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 9·6, or 0·6 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 4·5 in Rotherham, 5·1 in Croydon and in Swindon, and 5·2 in Wimbledon and in Edmonton, to 16·9 in Swansea, 17·0 in Burnley, and 19·7 in Wigan. The principal epidemic diseases caused 192 deaths, which corresponded to an annual rate of 0·6 per 1000, and comprised 71 from infantile diarrhoea, 48 from measles, 31 from diphtheria, 22 from whooping-cough, 14 from scarlet fever, and 6 from enteric fever. Measles caused a death-rate of 1·8 in Northampton and in Wigan, but the mortality from the remaining diseases showed no marked excess in any of the towns. There were 1755 cases of scarlet fever, 1599 of diphtheria, and 2 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1705, 1603, and 3 respectively at the end of the preceding week. The causes of 33 of the 3367 deaths in the 96 towns were uncertified, of which 4 were registered in London and 3 in Birmingham.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 13·3, 11·5, and 11·1 in the three preceding weeks, rose to 12·1 per 1000. The 227 deaths in Glasgow corresponded to an annual rate of 10·6 per 1000, and included 8 from infantile diarrhoea, 6 from measles, 2 from whooping-cough, and 1 each from enteric fever, small-pox, scarlet fever, and diphtheria. The 84 deaths in Edinburgh were equal to a rate of 12·8 per 1000, and included 3 fatal cases of diphtheria.

Irish Towns.—The 113 deaths in Dublin corresponded to an annual rate of 14·2, or 0·9 per 1000 above that recorded in the previous week, and included 5 from whooping-cough and 3 each from measles and infantile diarrhoea. The 104 deaths in Belfast were equal to a rate of 13·1 per 1000, and included 5 from infantile diarrhoea, 2 from whooping-cough, and 1 from enteric fever.

VITAL STATISTICS OF LONDON DURING JUNE, 1920.

In the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 6.0 per 1000 of the population, estimated at 4,358,309 persons; in the three preceding months the rates had been 7.1, 6.7, and 6.3 per 1000. Among the metropolitan boroughs the lowest rates from these diseases last month were recorded in Kensington, Hampstead, Stoke Newington, the City of London, Battersea, and Camberwell; and the highest in Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. The prevalence of scarlet fever was slightly greater than in the preceding month; this disease was proportionally most prevalent in Chelsea, Hackney, Shoreditch, Bethnal Green, Stepney, and Poplar. The Metropolitan Asylums Hospitals contained 1674 scarlet fever patients at the end of the month, against 1981, 1795, and 1671 at the end of the three preceding months; the weekly admissions averaged 251, against 240, 225, and 228 in the three preceding months. Diphtheria was somewhat less prevalent than in the preceding month; the greatest prevalence of this disease was recorded in Paddington, St. Pancras, Shoreditch, Bethnal Green, Poplar, Deptford, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1964, 1937, and 1783 at the end of the three preceding months, further fell to 1590 at the end of June; the weekly admissions averaged 189, against 260, 221, and 214 in the three preceding months. The prevalence of enteric fever was slightly less than in the preceding month; of the 31 cases notified during the five weeks ended July 3rd, 6 belonged to Wandsworth, 3 to Stepney, 3 to Poplar, and 2 each to Kensington, Hammersmith, Fulham, St. Marylebone, and Islington. There were 19 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 38, 29, and 18 at the end of the three preceding months; the weekly admissions averaged 3, against 6, 4, and 3 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, St. Marylebone, Finsbury, Bethnal Green, Poplar, Southwark, and Woolwich. The 11 cases of cerebro-spinal meningitis included 3 in Stepney and 2 in Wandsworth, while the 3 cases of poliomyelitis

belonged respectively to Islington, Holborn, and Finsbury. The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ended July 3rd the deaths of 4259 London residents were registered, equal to an annual rate of 10.3 per 1000; in the three preceding months the rates had been 17.6, 15.4, and 12.4 per 1000. The death-rates ranged from 8.0 in Woolwich, 8.3 in Chelsea, 8.7 in Hammersmith, 8.8 in Wandsworth, and 8.9 in St. Pancras, to 11.5 in the City of Westminster, 11.6 in Islington, 11.8 in Southwark, 12.0 in the City of London, 12.6 in Finsbury, and 13.7 in Holborn. The 4259 deaths from all causes included 273 which were referred to the principal infectious diseases; of these, 66 resulted from measles, 10 from scarlet fever, 65 from diphtheria, 48 from whooping-cough, 4 from enteric fever, and 80 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in Holborn. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in St. Marylebone, Stoke Newington, Wandsworth, Deptford, and Lewisham; and the highest in Chelsea, Finsbury, Shoreditch, Poplar, and Battersea. The 66 deaths from measles were 76 below the average number in the corresponding period of the five preceding years; this disease was proportionally most prevalent in Chelsea, the City of London, Southwark, Bermondsey, and Battersea. The 10 fatal cases of scarlet fever were 3 fewer than the average. The 65 deaths from diphtheria exceeded the average by 22; the greatest proportional mortality from this disease occurred in Fulham, Islington, Finsbury, Shoreditch, and Poplar. The 48 fatal cases of whooping-cough were 26 fewer than the average; this disease was proportionally most fatal in Paddington, Hampstead, Bethnal Green, Poplar, Camberwell, and Greenwich. Four deaths from enteric fever were registered during the month, against an average of 8; of these deaths, 2 belonged to Stepney. The 80 fatal cases of infantile diarrhoea were 20 in excess of the average; the greatest proportional mortality from this disease occurred in Chelsea, Islington, Finsbury, Shoreditch, Poplar, Southwark, and Lambeth. In conclusion, it may be stated that the aggregate mortality in London during June from these principal infectious diseases was 19.7 per cent. below the average in the corresponding period of the five preceding years.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JUNE, 1920.

(Specially compiled for THE LANCET.)*

CITIES AND BOROUGH.	Estimated civil population, 1919.	Notified Cases of Infectious Disease.											Deaths from Principal Infectious Diseases.											Deaths from all causes.	Death-rate per 1000 living.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other con- tinued fevers.	Pneumonia fever.	Erysipelas.	Cerebro-spinal meningitis.	Poliomyelitis.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping- cough.	Enteric fever.	Diarrhoea and enteritis (under 2 years).	Total. PELLAGRA.

To the Editor of THE LANCET.

SIR,—In an article on pellagra which appeared in your issue of May 8th last Dr. J. I. Enright criticises certain of the data and findings of the committee which, in 1918, investigated an outbreak of that disease amongst prisoners of war in Egypt. This reply, commenced long since and delayed by stress of military duty, is prompted by a wish to establish facts rather than to promote controversy. It is due, perhaps, to the present interest in this important subject; and certainly to the collaborators, especially Professor W. H. Wilson, with whom the "biological protein theory" of pellagra aetiology originated, who rendered Professor F. D. Boyd and me such invaluable aid in this investigation in Egypt.

The point at issue is, fortunately, quite definite. The committee's finding was that "lack of sufficient biological value of protein (in food) stands in aetiological relation to pellagra, certainly as an exciting factor and possibly as the determining factor. The deficiency may be (a) absolute or (b) relative, as determined by individualistic correlation between food assimilation and energy expenditure". Dr. Enright maintains that he finds evidence "sufficient to explode the food-deficiency theory as a predisposing factor" in the fact that pellagra occurred among German prisoners whose "diets both before capture and during their period of captivity were ample, both in quantity and quality, for any possible requirements."

It is a matter of keen regret to the committee that, as the first German case occurred ten days after they had reported their findings and dispersed, they thus had no opportunity of investigating these cases. It is, however, possible to apply to the diets quoted the "critical analysis" which is invoked in support of the conclusion that they were in all respects adequate. Happily the critic himself supplies sufficient material to prove that they were not adequate.

(a) The Pre-capture Diet.

Full details of the diet quoted were obtained from one prisoner. As regulations prescribe that all prisoners must be deprived of all official papers as soon as possible it may be assumed that these details were given from memory, and are devoid of documentary confirmation. Dr. Enright lays stress upon the great intelligence of these German prisoners, but he pays that intelligence a doubtful compliment by supposing that they—longing for "the flesh-pots of Egypt," and being asked to compare their former and present diets—were likely to make any other reply than that they had been "living on the fat of the land." Which land? At that time the food shortage in Central Europe was acute; in Palestine the Turks were so underfed that from August to November, 1918, the rations of one unit provided an average of only 2214 calories per diem (documentary evidence); while, despite all our resources, we had to reduce the rations of our troops by 10 per cent. Yet we are seriously asked to believe that 7000 Germans, serving from front to base alongside half-starved Turkish armies with demoralised transport, in a land foraged during nearly four years of war, were receiving a daily ration containing (in addition to purchased eggs) protein averaging 168 g. and with an extraordinarily high (maximum of 194 g., while all that we were then able to give our troops was 108 g. for Indian and 112 g. for European troops. Surely the faith in German veracity which can build a scientific argument upon such evidence as this is beyond the ordinary mortal. Upon closer examination the quoted ration bears intrinsic evidence of its own improbability; it is difficult to conceive that scientific Germans, late in the war, should include under one heading of alternative issues articles of such totally diverse values as cheese, butter, and jam.

Finally, Dr. Enright throws an interesting light upon his opinion that their diets "were ample for any possible requirements" by mentioning that two of these German prisoners were found to be suffering from scurvy. It is certainly most remarkable that men receiving a daily ration of "453 g. fresh vegetables, or 226 g. of beans, peas, rice, or potatoes, and 350 g. fresh meat," supplemented as indicated by the statement that there was "certainly no lack of fresh fruit in Palestine and Syria during the enemy occupation," should develop scurvy. Among all the diseases which they might have got, these two cases were so inconsiderate as to acquire the particular one most fatal to the contention that they were perfectly fed. Criticisms which contain such conclusive evidence in their own despite must surely be rare.¹

There are, however, few of the cases whose pre-pellagrous period of captivity is stated which require that a pre-capture food-deficiency, however probable, need be even assumed. From Dr. Goldberger's scientific experiment, and our experience in the outbreak of pellagra among Armenian refugees in Egypt, it appears legitimate to conclude that the antecedent food-shortage period coincided with that during which these German pellagrins were in captivity. The following table shows that this applies to 70 per cent. of the cases quoted:—

Month of captivity.	Onset of pellagra symptoms.	Month of captivity.	Onset of pellagra symptoms.
1st	No cases.	5th	13 cases } 70%
2nd	No "	6th	9 "
3rd*	2 "	7th	5 "
4th	3 "		

* 3rd week.

We may therefore next consider the evidence advanced that the German prisoners' diets preclude the possibility of pellagra being due to protein deficiency.

(b) Post-capture Diets.

Dietaries of camps and hospitals require separate consideration. As Dr. Enright lays special stress upon the two cases from Maadi Camp, that issue is readily accepted first.

(i.) In camps.—This camp, situated amongst cultivated lands close to the Nile, was visited by the committee on Nov. 28th, 1918, with special reference to the fact that no German case had been reported there, while the adjacent Turks had provided 60 pellagrins in the preceding two months, thus providing the M.O.'s common to the two compounds with ample diagnostic experience. As no European case had occurred in Egypt when we wrote our report, we recorded our findings thus: "At Maadi over 2000 Germans, Austrians, and Bulgars have, for the last two years, occupied a compound immediately adjoining that occupied by some 6000 Ottomans. The occupants of both compounds have been living under similar conditions as regards water-supply and conservancy, equally exposed to biting insects and sunlight, and similarly protected against summer heat by matting sun-shelters, and against winter cold by two blankets and a great-coat per man. The only obvious difference was that of diet; the Ottomans lived upon their rations, while the Germans, being freely supplied with money through a consulate, supplemented their rations lavishly. During these two years no single case of pellagra had occurred among these Germans, Austrians, or Bulgars, nor was any suspicious case found on careful inspection by one of us (F. D. B.). This formed a most striking contrast to the 300 pellagra cases which had occurred during the present year from among the Ottomans—both Turks and Arabs—the great majority of whom had also been in captivity for long periods in this camp." I may add that Professor Boyd, whose diagnostic ability had been accentuated by great experience of pellagra in its very earliest stages, failed to find a single suspicious case in the sample batch (200, I think) of Germans examined there.

Careful investigation showed that practically the whole of the 2s. a day supplied to the Germans passed

¹ Since this was written this point has been anticipated by a communication, published in THE LANCET of July 3rd (p. 41), from Dr. J. Goldberger.

through the canteen accounts, and detailed study of those accounts provided the actual amounts of various foods sold. We were thus enabled to work out the average additions thus made to the ration. These diets may be thus compared:—

	Protein.		Fats.	Carbo- hydrates.	Calories.
	B.V.P.*	Gross.			
Turks	39.1	92.0	27.55	515	2744
Germans, rations only	58.3	92.7	33.47	341	2087
" rations and extras	89.7	144.3	120.67	458	3589

* B.V.P. is used here and subsequently as a useful abbreviation of "biological value of protein."

The Turks' unsupplemented ration afforded just under the "B.V.P." minimum of 40 g. per diem, as laid down by Professor Wilson. They became pellagrous in many instances.

The criticism regarding the German cases rests upon the assumption that their ration provided an adequate amount of protein, if any of them lived upon it alone. It is not easy to understand a critic missing the cardinal essentials underlying the word "relative" applied in our report to food deficiency. It appears strikingly obvious that—no matter what the protein intake may be—the tissues must suffer deficiency if their needed amino-acids fail to reach them because of being spent to make good a deficit in the total energy balance-sheet; income which is spent, as soon as received, on debt reduction will not serve to keep the recipient from starvation. The German ration provides 133 calories less than the 2200 daily expended by the average man "at rest"; that deficit is balanced by combustion of 32.4 g. of assimilated protein; the "B.V.P." available for supplying the tissues with amino-acids is thus reduced from 58.3 to 40.9 g. daily. This affords so slight a margin over the minimum of 40 g. as to render those Germans living wholly on their rations liable to loss of that trivial margin of safety by any trivial further disturbance of nitrogenous metabolism. Any lessening of protein assimilation (as by digestive disturbance) or any increase in energy output (as by exercise, cold, or individual bulk above the average) must suffice to reduce the available "B.V.P." below 40 g. and convert this ration into a diet such as, if long continued, we have found associated with the occurrence of pellagra.

Naturally this leads to the question of whether or not any of these Germans—and particularly these two pellagra cases—lived upon their rations. As Dr. Enright does not even mention so crucial a matter, one can only infer that it escaped his attention, and that a unique opportunity—such as can hardly recur—of establishing the precise diets of these two patients, and thus adding precise scientific data of obvious importance, was lost. Thus, again, probabilities have to be weighed; but in this case there is small room for doubt. It is only necessary to assume that 2 of 2224 prisoners in this camp lived upon their rations, and the whole criticism fails. The armistice, late in November, 1918, brought the possibility of transmitting money to Germany. It would, indeed, be remarkable if there were not, among 2224 men, two who hoarded their money allowance with a view to sending it home to their families. It would be no less remarkable if there were not here—as in the Turkish labour prisoners' camp—some inveterate gamblers who gambled away every cent. that they received. We are not even told whether the money was still continued to be supplied to these men, and the "critical analysis" invoked appears to have been in abeyance.

What applies to the German prisoners at Maadi also applies to those in other camps, and we are thus left with only the hospital diets to consider.

(ii). *In hospital.*—This concerns the cases cited as having been in hospital for other conditions for some considerable period before appearance of the diagnostic pellagrous rash. First it is noted that Dr. Enright refers to a "prodromal stage" in these cases, which preceded the rash by from 8 to 16 weeks, during which

there occurred, among other symptoms, "obstinate diarrhoea with passage of undigested matter," while "in some there was anorexia." During this period these patients thus ingested less, and lost more, protein; all had diarrhoea, and 9 of the 25 had dysentery. There was a further loss of assimilated protein, by indicanuria. In fact, it is evident that, as Dr. Enright puts it, "there was abnormal protein decomposition (in the bowel), and the ultimate good effects of the diet were largely vitiated or entirely lost in this manner."

This is most interesting as a corollary to results obtained by Professor Wilson and Captain H. E. Roaf by careful study of the nitrogenous equilibrium of a group of Turks selected by Professor Boyd, from a non-labour prisoners' camp, as free from any signs of pellagra. Their loss of nitrogen by malassimilation amounted to 33.6 per cent. of that ingested, as compared with 35.1 per cent. for definite pellagrins, and only 23 per cent. for what Professor Wilson's experience indicated as normal to the country. We also found that marked hypochlorhydria is one of the earliest features of established pellagra. The special interest of these findings lies in correlating them to the fact that such apparently healthy prisoners, selected (by pellagra experts) from volunteers in non-labour camps where many of them had been confined for long periods, became definitely pellagrous remarkably quickly (within three weeks in some instances) after transfer to labour camps. Whether these men were in the "prodromal stage," or were recurrent cases whose initial attack had been overlooked, it appears that malassimilation had so reduced their protein nutrition that they had become borderland persons, liable to become actively pellagrous on the least increase of energy expenditure sufficient to break down their precarious nitrogenous equilibrium.

If there be indeed in pellagra a "prodromal stage" during which protein assimilation is reduced in the manner suggested, and to the extent indicated by these clinical notes, then it follows that deficient biological value of protein in the diet must play a most important part in the progress of the case towards establishment of a vicious cycle, which, by the action and reaction of malassimilation and putrefactive diarrhoea, must eventually make recovery impossible.

It is thus apparent that in these hospital cases under consideration the adequacy of their diets cannot be considered apart from the factor of protein mal-assimilation and loss; in other words, they must have suffered a "relative" deficiency.

To the article under review we owe details which enable us logically to follow the indicated processes in the reverse direction consequent upon recovery of such patients as had not progressed to an irrecoverable stage. Checking of putrefactive diarrhoea initiated recovery: "If the stools became solid they gradually became better." If taken sufficiently early they recovered on the simple treatment of rest, which limited their energy output, and improved dieting. It is remarkable, further, that the items which Dr. Enright's experience led him especially to include in the increased diet should be those so especially rich in "B.V.P." as 7 oz. of meat and two eggs per diem.

To summarise: the disease is apparently cured if no other treatment be adopted than that of checking protein loss, lessening energy expenditure, and increasing protein intake, especially as regards its biological value of protein.

In conclusion, two other points may perhaps be referred to very briefly. The first is Dr. Enright's question as to why pellagra should not have occurred in the Central Powers during their food-shortage period of the war. In a report sent to the War Office by the D.M.S., Egypt, it is stated that "A few German Red Cross orderlies knew of the disease (pellagra), having seen it in Austria." Moreover, we have the evidence of Dr. Kulz. I quote these as two items which have just chanced to come to my notice without my having had an opportunity to make any inquiries in this direction.

The last point is the very pertinent question—Why did not any of the many dysenteric, and other, cases among the British Forces of the B.E.F. who suffered from so marked a malnutrition become pellagrous? It

may be that a primary attack of pellagra only follows a long-continued deficiency in "B.V.P." such as these troops never experienced in the field, while the onset of wasting dysentery was so promptly met by rest in bed and appropriate milk diet that the malassimilation resulting was met from the outset by so complete a conservation of energy that relative insufficiency was not established. It must, however, be frankly admitted that this explanation is not convincing.

Is the deficiency factor only a contributory factor to a determining cause yet to find? If so, the suggestion that the latter is to be sought in an helminthic infection such as ascaris is equally difficult of acceptance, because the apparently healthy Turks were equally infected with the pellagrous, and the immune Indian troops were heavily infested by ascaris, if my recollection serves me well with regard to the findings of Major F. W. Stewart, I.M.S.

I am, Sir, yours faithfully,

P. S. LELEAN,

Lieutenant-Colonel, R.A.M.C.; Professor of Hygiene.
R.A.M. College, July 11th, 1920.

MEDICAL EXPERIENCES IN MACEDONIA AND THE CAUCASUS.

To the Editor of THE LANCET.

SIR,—Dr. Arthur Phear, in a lecture on his experiences in the East, which was given before the Royal Society of Medicine and published in THE LANCET of July 10th, refers to my observations on quinine which appeared in the *Journal of Hygiene* in October, 1919. Dr. Phear has given a condensed account of his experiences of various diseases, and a still more condensed abstract of my observations; in fact, he omits the essential points, but a relatively lengthy criticism follows. I showed that when quinine is injected intramuscularly, in concentrated or dilute solutions, it is absorbed with remarkable rapidity. At the end of two hours from the time of the injection the majority of the quinine has been removed. This was found to be the case in man, and in mules which were inoculated experimentally. This fact, which is of very great importance, is not referred to by Dr. Phear. The injection of any preparation of quinine into muscles, or subcutaneously, produces tissue necrosis which may be extensive. Animal experiments have shown that disasters will occur if the injections are not made correctly, and the complications which arise are, as would be expected, exactly those which are met with in the human subject. In my paper I have given a list of the complications which *did occur* among men injected intramuscularly with quinine, and some of these complications were of a very serious nature. Dr. Phear, apart from some cases of dysentery, never met with any serious complication. There are a very large number of others who will entirely agree with him, but, in my opinion, if it is fully recognised that serious troubles may arise unless the dangers, and how to avoid them, are fully understood, then quinine injections will not be regarded with apprehension. The remarkable fact that many thousands of injections of quinine were given during the war alone without mishap is great testimony to the recuperative power of the tissues. A distinguished member of the medical profession wrote to me in reference to my paper on quinine as follows: "No one should be allowed to inject toxic substances such as quinine into the tissues of his fellow creatures until he is fully acquainted with the dangers, which should be learnt by animal experiment."

I am, Sir, yours faithfully,

London, July 12th, 1920.

LEONARD S. DUDGEON.

PHYSICAL ELEMENT IN PSYCHONEUROSES.

To the Editor of THE LANCET.

SIR,—I, like Dr. Judson Bury, "have been much impressed by the frequency with which relapses have occurred in cases which had been discharged from Maghull, Seale Hayne, and other neurological hospitals as either cured or improved," and I am glad to find that the medical profession is beginning to appreciate the folly of imaginin that it is possible permanently

to cure psychoneuroses in a few minutes by suggestion, persuasion, &c. It is possible, and easy, it is also wise, to remove certain troublesome symptoms in this way; but it is not possible thus to replace suddenly the lost "ergogen" in the brain cells or to prevent relapse. All hysterical patients become also neurasthenic in time, unless their improvement by psychotherapy is confirmed into cure by country work and convalescence. At one period I could have sent away at a time 500 to 600 sufferers from war neuroses separately (and this is important) to light work in the gardens of England, Scotland, and Ireland; but the Government departments concerned were hoodwinked by the wonder-workers, the ten-minute curers, who misled themselves by not following up their cases, and dazzled the mental vision of the authorities by the evanescent brilliance of their immediate results.

Now that the Country Host Scheme has been taken over by the Red Cross and that private enthusiasm has diminished, I fear there is much difficulty in finding hosts, but I am still seeing very many neurasthenics who urgently need non-institutional convalescence and who probably will not recover permanently till they get it. Could not our country confrères persuade landed proprietors and others in their district to act as "hosts" to single neurasthenics, who would live with the gardeners for two or three months and work with the latter, not for pay but by way of treatment?

Any "host" willing to receive such a patient should communicate with the County Director, Red Cross (Country Host Scheme), 27, Grosvenor-place, London, S.W. 1.

I am, Sir, yours faithfully,

THOMAS LUMSDEN.

South Eaton-place, S.W., July 9th, 1920.

THE TEACHING OF OBSTETRICS.

To the Editor of THE LANCET.

SIR,—In a leading article in THE LANCET for July 3rd it is stated that—

"We believe it is only the Universities of Oxford and Cambridge which require that the student shall actually receive practical instruction in lying-in wards before presenting himself for his examination in midwifery."

In the Calendar of the University of Leeds, 1919-20, p. 409 et seq., the regulations for candidates read thus:—

Hospital work—In Obstetrics (a) of having attended during not less than one month the indoor practice of a Lying-in Hospital or the Lying-in Wards of a general hospital approved by the University, and (b) having personally conducted not less than twenty cases of labour, &c.

For many years this rule has been complied with. Each student attends for one month and receives practical instruction at the Leeds Maternity Hospital (70 beds) before being allowed to attend cases in the district. I may add that arrangements are now being made to carry out the suggestions of the General Medical Council in a more complete manner than formerly possible. It may not be without interest to state that candidates for the final examination are required to undergo a clinical examination in gynaecology, and I think that this university was the first to carry this idea out some 12 or 15 years ago.

I am, Sir, yours faithfully,

E. OCTAVIUS CROFT,

University of Leeds, July 8th, 1920. Professor of Obstetrics.

THE BIOCHEMISTRY OF MICRO-ORGANISMS.

To the Editor of THE LANCET.

SIR,—The short report, appearing in THE LANCET of June 26th, of a paper on detoxicated vaccines which I read at the Brussels Congress (Royal Institute of Public Health) in May was misleading, and I should like to give a short résumé of my work, during the past two years, on the detoxication of vaccines, which has largely developed into a study on the biochemistry of micro-organisms. Whilst researching on the biochemical composition of germs I have carried out at the same time a parallel series of investigations on various tissues of animals and certain plants.

All bacteria are closely related in their biochemical composition to animal tissues, and consist largely of

protein substances. On the other hand, they differ materially from plant tissues in that they apparently contain no cellulose. My researches have shown that bacteria and animal tissues can be split up in the same manner into three main groups of substances—viz., alkali soluble material, acid soluble material, and alcohol soluble material. The relative proportions of the alkali, acid, and alcohol soluble fractions of different germs and animal tissues vary very greatly; for example, the gonococcus consists of 90 per cent. alkali soluble, 9 per cent. acid soluble, and 1 per cent. alcohol soluble substance, whereas the tubercle bacillus contains 40 per cent. alkali soluble, 30 per cent. acid soluble, and 30 per cent. alcohol and chloroform soluble material. No two germs give the same quantitative proportions and thus it is possible to diagnose a given germ by biochemical analysis alone without resorting to the microscope. The same is true of tissues. Brain tissue is remarkable in containing an enormous proportion of alcohol and chloroform soluble lipid material (about 50 per cent.), whereas the alkali and acid soluble fractions are correspondingly low. Muscle tissue, on the other hand, is rich in alkali and acid soluble material and comparatively poor in alcohol soluble substance.

The quantitative biochemical analysis can be carried, however, much further, since it is possible to split up the alkali and acid-soluble fractions into subgroups. Thus, the alkali-soluble material may be subdivided further into (a) metaprotein, which is thrown out of alkaline solution on neutralisation with acid; (b) primary proteose, which is thrown out of the neutral solution by half saturation with ammonium sulphate; (c) secondary proteose, which is precipitated by full saturation with ammonium sulphate; (d) a brown material not precipitated either by full saturation with ammonium sulphate or absolute alcohol. This subdivision of the main groups makes it possible to separate the toxic fractions from each. When the metaprotein and proteoses are thrown out of solution by neutralisation, ammonium sulphate or alcohol, the toxic substance remains in the supernatant fluid. It can also be removed from the precipitates by simply washing the latter with alcohol or water or both.

In the case of the secondary proteose precipitates, which are largely soluble in water, the toxin must be removed by washing with absolute alcohol. The toxic material is light straw in colour when dilute and dark reddish brown, like port wine, when concentrated. It appears to be identical with the substances excreted in urine. It is well known that urine is toxic. In other words, it would appear that by this process of detoxication there is removed from the germs or tissues the same harmful and useless substances that are excreted by living animals in the urine. The brown toxic material, so far as I can ascertain, is not antigenic (produces no immunity). The other non-toxic fractions of the germs, on the other hand, are definitely antigenic (immunising), as estimated by the complement-fixation test and by inoculation experiments. The first detoxicated vaccines, which I described in THE LANCET of June 28th, 1919, were composed only of the alkali-soluble metaprotein part of the germs. Now I include in addition all the other antigenic fractions—viz., the proteoses, the acid-soluble and the alcohol-soluble lipid portion, each of which is detoxicated separately. In other words, every part of the germ is now included except the actual endotoxins.

Another point of great interest is the fact that the proteoses have a provocative action. For example, the proteose fraction of the gonococcus when injected subcutaneously provokes a focal reaction at the site of the disease. In a disease like gonorrhoea this provocation does no harm and I include the proteoses in this vaccine because they are antigenic. In systemic diseases, however, like tuberculosis or pneumonia, it is doubtful if the proteoses of the tubercle bacillus and the pneumococcus should be included in the vaccines, since a provocative focal reaction in the chest in such conditions might be undesirable. At the present time I am endeavouring to ascertain whether detoxicated tubercle bacillus vaccine is better with or without the proteoses. With the vast majority of germs, detoxicated vaccines are

some ten to one hundred times less toxic than ordinary vaccines. In the case, however, of the typhoid and coliform group of germs, the detoxication is not so marked. I am inclined to attribute this to the fact that the bacteria of this group have a very much higher percentage of proteoses in their composition than those of any other group so far examined.

I am, Sir, yours faithfully,

DAVID THOMSON,

New Cavendish-street, W., July 8th, 1920. Lecturer and Research Pathologist to the London Lock Hospital.

THE ILLNESS OF MR. CLIFFORD ALLEN.

To the Editor of THE LANCET.

SIR,—I enclose a statement by Mr. Bertrand Russell and myself on the illness of Mr. Clifford Allen while with the British Labour Delegation in Russia, to which I was attached as physician and secretary. Mr. Russell and I are anxious to have our own signed statement circulated because a matter of principle of first-class importance both to individuals and doctors emerges from it. Mr. Allen is getting better and is now on his way to England.

I am Sir, yours faithfully,

Tite-street, S.W., July 12th, 1920.

L. HADEN GUEST.

ENCLOSURE.

British Labour Delegation to Russia and the Illness of Mr. Clifford Allen.

On May 30th, while the British Labour Delegation was on the Volga, Mr. Clifford Allen became suddenly ill with acute pleurisy and pneumonia originating from the latent phthisis from which he had suffered. Before the delegation left England for Russia, Mr. Allen was medically examined and was found in good health and free from any active disease, and had so remained free for one year. Mr. Allen was, therefore, considered fit to travel. During the four days after the beginning of the illness, during which the boat proceeded down the river to Saratoff, Mr. Allen became very gravely ill indeed, and Dr. Haden Guest warned the members of the delegation that his life was in great danger. It had been arranged that the delegation should return to Moscow by train from Saratoff. On arrival at Saratoff Allen had a hæmorrhage which made it dangerous to move him.

Three courses were possible with regard to Mr. Allen: (1) to leave him in a sanatorium in Saratoff; (2) to take him by train with the rest of the delegation to Moscow; (3) to let him remain on the boat and proceed with it to Astrakhan. To both of the first two courses there was the insuperable objection that he could not be moved on that day without danger to life, and as accommodation on the boat was comfortable, and there was a Russian doctor and a good Russian nurse attached to the boat, and food, especially milk, was more easily obtainable on the boat than in any town in Russia, as it was obtained directly from the villages en route, it was decided to keep Mr. Allen on the boat. The Russian doctor on board, Dr. Dmitrieff, agreed entirely with the decision which was arrived at—namely, that Mr. Allen should remain on the boat. We proceeded to Astrakhan and from there returned to Saratoff.

Mrs. Philip Snowden and Mr. Bertrand Russell remained with Dr. Haden Guest to help in the nursing. At Astrakhan Dr. Haden Guest called in a consultant, who took an even graver view of the case and regarded it as hopeless. Nevertheless, by the time the boat arrived at Saratoff Allen was sufficiently recovered to be moved and fit to travel as a lying down case. By the kindness of B. M. Sverdloff, Acting Minister of Ways and Communications, who had been on the boat throughout Mr. Allen's illness, a special saloon coach was provided and arrangements were made to enable Mr. Allen to remain in this coach until his arrival at Revel in Esthonia, as well as for accelerating his journey. Partly on account of the impossibility of communicating with his friends in Western Europe and partly for other reasons Mr. Allen so urgently desired to get to Revel, as to make it almost impossible for him to sleep or rest while in Russia. This gravely aggravated his condition and made his departure imperative on medical grounds.

On arriving at Moscow and presenting ourselves at the Foreign Office for visas, we learnt that the Government had decided to keep Mr. Allen in a sanatorium in Moscow pending a medical examination by doctors chosen by themselves. At first Titcherine was unwilling to allow this examination to take place immediately in the train, in spite of our both stating to him that we considered Mr. Allen's speedy departure of the utmost importance for saving his life. It was only after we had both made strong and formal protests against the Government decision, which we regarded as gravely increasing his danger, that Titcherine decided to

send the doctors to the train at once. Much as we regret having been forced into any unpleasantness, we think it necessary to state that we only adopted this method after we found that all milder methods were unavailing. Four doctors were sent to take part in the examination of Mr. Allen, of whom two, Professor Popoff and another, actually performed the physical examination.

Dr. Dmitrieff and Dr. Haden Guest were also present. After examination the professors entirely agreed with Dr. Haden Guest that Mr. Allen was fit to travel and visas of passports were issued during the night, the train leaving Moscow on the following day. At Revel arrangements were made by Dr. Haden Guest to have Mr. Allen removed to the Diakonisse Nursing Home, the American Red Cross lending their ambulance and the British Mission rendering every possible assistance.

The doctor at the nursing home at first took a very grave view of the case, but at the end of two days pronounced Allen out of immediate danger. During the first week of his stay at Revel Mr. Allen made rapid progress and is looked after by an English-speaking nurse, who will accompany him to England if he so desires.

(Signed) BERTRAND RUSSELL.
L. HADEN GUEST.

July 2nd, 1920.

"PITUITRIN."

To the Editor of THE LANCET.

SIR,—Will you allow me to state that in the case of rupture of the uterus recently reported in THE LANCET from a paper I read before the Obstetrical Section of the Royal Society of Medicine I wrongly used the word "pituitrin" to designate the extract of pituitary gland which was employed. It has been pointed out to me that "pituitrin" is the name exclusively used for the product prepared by Parke, Davis, and Co., and in this particular case it was not the preparation of this firm which was administered.

I am, Sir, yours faithfully,

Harley-street, W., July 12th, 1920. ALECK W. BOURNE.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, JULY 7TH.

Small-pox in Glasgow.

Mr. WATERSON asked the Minister of Health if he would state how many cases of small-pox had occurred in the city of Glasgow this year.—Mr. C. D. MURRAY (Solicitor-General for Scotland) replied: The number of cases of small-pox in Glasgow up to July 2nd was 306.

Exhumation of American Soldiers.

Lieutenant-Colonel BUCKLEY asked the Minister of Health if bodies of American soldiers interred in the Liverpool district were being exhumed for transfer to America, and if so, would he state where these bodies were being reconfined and what arrangements were being made to avoid risk of infection.—Mr. SHORT (Home Secretary) replied: The reply to the first part of the question is in the affirmative. These removals are being carried out by the United States military authorities with the aid of an expert staff, and with the most careful precautions against the possibility of any risk to the public health. The remains are thoroughly disinfected immediately on the coffin being opened, and are at once replaced in a metal case which is hermetically sealed. This takes place in the cemetery, and is completed in a very short time after the exhumation. I am satisfied that no danger to the public health need be entertained.

Chairman of General Nursing Council.

Mr. ALFRED DAVIES asked the Minister of Health whether he appointed the present chairman of the General Nursing Council set up under the Nurses Registration Act without consultation with the members of the Council, and if so, would he state his authority for this action.—Mr. ROBERT RICHARDSON asked the Minister of Health whether he was aware that the chairman of the General Nursing Council had neither experience nor knowledge of medical or nursing matters sufficient to enable him to understand and to guide the General Nursing Council in its deliberation on professional subjects.—Dr. ADDISON replied: The General Nursing Council has to prepare statutory rules to perform judicial functions in relation to the removal of unfit persons from the register, and in view of the amount of quasi-legal work devolving on them I thought it desirable to appoint a chairman with legal experience, and I was fortunate in being able to persuade Mr. Priestley, K.C., to accept this post. I

was not under any obligation to consult the members of the Council, and I accept full responsibility for the appointment.

Refuse Dumps at Greenford.

Mr. MOSLEY asked the Minister of Health whether he would make immediate inquiries into the dumping of refuse from Marylebone by canal into the district of Greenford, Middlesex, in view of the fact that a swarm of rats and flies, attracted by this refuse, constituted a grave danger to the health of the inhabitants of Greenford.—Dr. ADDISON replied: I have already arranged to have these refuse dumps inspected at an early date.

The Finance Bill: Income-tax Relief to Foreign Invalids.

The House went into Committee on the Finance Bill, Mr. Whitley in the chair.

On Clause 23, which provides that no relief in respect of income-tax shall be granted to an individual resident outside the United Kingdom unless they can satisfy the Commissioners of Inland Revenue that they are (a) a British subject, (b) that they are or have been in the service of the Crown, or employed in the service of any missionary society or in the service of any native State under the protection of His Majesty, (c) they are resident in the Isle of Man or the Channel Islands, (d) have previously resided within the United Kingdom and are resident abroad for the sake of their health, or (e) that the claimant is a widow whose late husband was in the service of the Crown.—Mr. G. LOCKER-LAMPSON wanted to confine the operation of Paragraph (d) to persons of British birth. The Chancellor, he said, was apparently going to allow a person who was not of British birth, and who left the United Kingdom to go abroad for the sake of his health, to obtain relief. He did not see why relief should be given to a foreigner, who very likely went back to his own country.—Mr. BALDWIN (Financial Secretary to the Treasury) said he hoped that the amendment would not be pressed. He could quite understand his honourable friend's feelings, because many of them still felt that they did not want any of the advantages which were given to English people to be given to Germans, but this was not confined to Germans. There were genuine cases of people who had lived in this country for the best part or all their lives, who belonged to friendly and allied nations, and he did not think that they should take away from these people by Statute a privilege that was enjoyed by all others who were resident in this country, if and when the circumstances arose.—The amendment was negatived.

Eaton Hall Hospital, Chester.

Mr. ROBERT YOUNG asked the Secretary for War whether Eaton Hall, Chester, was now closed as a hospital; and whether he could state the number of officer patients in residence at the end of April and later monthly periods, along with the number of staff employed there at the end of each month since Dec. 31st last.—Mr. CHURCHILL replied: Yes, Sir. Eaton Hall is now closed as a hospital. The number of officer patients in residence on the dates mentioned was as follows: April 30th, 1920, 62; May 28th, 8; June 4th, nil. The staff employed was as follows: Jan. 4th, 1920, 108; Jan. 25th, 107; Feb. 29th, 110; March 28th, 88; April 25th, 83; May 30th, 41.

Women's Hospital, Clare Market.

Mr. ALFRED T. DAVIES asked the Minister of Health whether he was now in a position to announce the result of his representations to the authorities of the Sheffield-street Hospital for Women at Clare Market, W.C.2, with reference to the appointment of two men doctors to the posts of medical officers and assistant medical officers, respectively, and to the desirability, admitted by the Ministry of Health, of appointing women to posts of this kind.—Dr. ADDISON replied: I have now been informed by the authorities of the hospital that the desirability of selecting women for posts of this character will receive special consideration in connexion with any future appointments.

Invalids' Flour.

Mr. WADDINGTON asked the Food Controller what was the method adopted in appointing grocers in Lancashire towns for the sale of white flour for invalids, and whether the number of these appointments had any regard to the population in the district; was he aware that in some towns of large population only one grocer was appointed, and this caused great inconvenience to those requiring the white flour; and would he make further appointments where reasonably required.—Sir W. MITCHELL-THOMSON (Parliamentary Secretary to the Ministry of Food) replied: The number of retailers specially authorised to supply imported flour under the Invalids' Flour Scheme has been determined with due regard to the population in each district, but the Minister of Food is prepared to make further appointments where representations justifying this course are made to him.

Tetanus in the Great War.

Mr. WATERSON asked the Secretary of State for War whether he could state the incidence of tetanus in the

recent war as regards wounded men brought to England, wounded men nursed in France or other parts of the continent, wounded men in Mesopotamia, and wounded men in Gallipoli and Egypt and other theatres of war, giving the attack-rate and the death-rate per thousand wounded in each case.—Mr. CHURCHILL replied: I regret that complete statistics are not yet available. For the period from August, 1914, to December, 1918, the number of cases of, and deaths from, tetanus reported in France, Belgium, and the United Kingdom among the troops wounded in France and Belgium gives approximately an attack-rate of 1.22 per 1000 and a death-rate of 0.49 per 1000. I have no figures at present regarding the incidence of tetanus in the other theatres of war mentioned, but I am informed that very few cases occurred in any of them.

MONDAY, JULY 12TH.

Indian Medical Service.

Sir W. JOYNSON-HICKS asked the Secretary for India whether he had arrived at any decision as to the future of the Indian Medical Service.—Mr. MONTAGU replied: I shall be in a position to decide on this question and to make an announcement when I receive the Government of India's recommendations on the Reports of the Army in India Committee (in so far as it deals with military medical organisation in India) and of Sir Verney Lovett's Committee on Medical Services in India. The two reports have to be considered together. Copies of the Lovett Committee's Report for publication are on their way to England, and I hope to publish the two Reports simultaneously very shortly. Meanwhile copies of the Report of Lord Esher's Committee have been sent to the Government of India, who will forward as soon as possible their views on both Reports. The following press communiqué was issued from the India Office on July 5th containing the revised rates of pay for the Indian Medical Service; also a copy of a letter which was sent to the British Medical Association on June 22nd dealing with the questions of pay allowances, pensions, passages, and leave reserve of the service, and the official status of the Director-General and Surgeons-General.—The Secretary of State for India, after consultation with the Government of India, announces the following increased rates of pay for regular officers of the Indian Medical Service, which take effect from Jan. 1st, 1920. The combined rates of basic pay and overseas allowance apply to all officers who were in the permanent service on Dec. 1st, 1918, and to all British officers who have joined or may join the service after that date. Indian officers who have joined or may join the service after Dec. 1st, 1918, will draw, as from Jan. 1st, 1920, pay in accordance with the basic scale set forth below, unless they are already drawing pay at a higher rate, in which case they will continue to enjoy the benefit of that rate for so long as they would otherwise have done; but they will not receive any further increment until it is due to them under the basic scale. The arrangements affecting Indians who join the service after Dec. 1st, 1918, are provisional. Exchange compensation allowance will not be admissible.

Rank.	Year of service.	Basic pay.	Overseas allowance.	Total basic pay and overseas allowance.	Rank.	Year of service.	Basic pay.	Overseas allowance.	Total basic pay and overseas allowance.
Lieut.	1	Rs. 500	Rs. 150	Rs. 650	Major ...	13	Rs. 950	Rs. 250	Rs. 1200
	2	500	150	650		14	950	250	1200
	3	500	150	650		15	950	250	1200
Capt. ...	4	650	150	800	Lieut.-Col. ...	16	1100	250	1350
	5	650	150	800		17	1100	250	1350
	6	650	150	800		18	1100	250	1350

						Over 25 on S.L.	1700	250	1950
							1850	250	2100

S.L. = Selected List.

Charge allowances and second-in-command allowances for station hospitals will be admissible in addition to the above rates of pay at the following rates:—

(a) Charge Allowance.	(b) Second-in-Command Allowance.
Rs. per mensem.	Rs. per mensem.
1st class hospitals ... 240	1st class hospitals ... 120
2nd class hospitals ... 180	2nd class hospitals ... 90
3rd class hospitals ... 120	
4th and 5th class hospitals nil.	

Dated 5th July, 1920.

The following is the letter referred to:—

India Office, Whitehall, S.W.1., June 22nd, 1920.

SIR,—In continuation of this Department's letter of the 5th instant, No. M.4784, I am directed to address you on certain questions affecting the Indian Medical Service. The Secretary of State understands that in the course of interviews which have taken place between the Medical Adviser at the India Office, on the one hand, and the Chairman of the Naval and Military Committee of the Association and the Editor of the *British Medical Journal* on the other, the following proposals were put forward on behalf of the service:—

1. *Pay.*—The pay of officers to be calculated on the pre-war scale for charge of a regiment, but to be approximately 50 per cent. in excess of that.

2. *Allowances.*—(a) Allowances to be granted for the charge of Indian station hospitals. (b) Allowances not to be reckoned as part of the 50 per cent. increase, but as additional to it. (c) All existing general allowances paid to holders of professorial and bacteriological appointments and certain other special classes of appointments on the civil side to be maintained.

3. *Pensions.*—The same relative consideration to be given to officers of the Indian Medical Service as to combatant officers of the Indian Army. (The maximum for the Director-General, Indian Medical Services, being £150 a year.)

4. *Passages.*—Officers of the Indian Medical Service in military employ to receive the same concessions in the matter of passages as combatant officers of the Indian Army. Officers of the Indian Medical Service in civil employ to receive the same treatment as officers of other Civil Services in India.

5. *Status of the Director-General and Surgeons-General.*—These officers to have the same rights as the Secretary to the Government in the matter of (a) direct access to the Viceroy or Governor, as the case may be; (b) access to documents, and opportunity of forwarding their views to the Viceroy or the Governor, as the case may be.

6. *Leave Reserve.*—The cadre of the Indian Medical Service to have a reserve of 25 per cent. for furlough, and 2½ per cent. for study leave, whenever this may be practicable.

Points 1 to 3 above have already been disposed of in this Department's letter of June 5th cited above, and the Secretary of State is about to make a public announcement, communicating the reorganisation of the pay of the Service.

As regards pensions, I am to refer you to the memorandum dated 3rd instant, issued by this Office, communicating the revised rates of pension for officers of the Indian Army and of the Indian Medical Service.

As regards passages, there has as yet been no decision on the question of passages for combatant officers, but the Secretary of State is willing to undertake that officers of the Indian Medical Service in military employ will receive the same advantage as those officers, and that those in civil employ will receive such concessions, if any, as may be granted to other offices in civil employ.

The Government of India reported in a despatch dated Feb. 26th that they had already agreed to the principle that the Director-General and Surgeons-General with provincial Governments should have the right to place their views direct before the Viceroy or Governor when necessary, and that they were then considering the best means of giving effect to that decision. In the meantime, the Secretary of State accepts point 5.

The Secretary of State undertakes to carry into effect the proposals for a 25 per cent. leave for furlough, and 2½ per cent. reserve for study leave, as soon as the strength of the Service permits.

I am, &c.,

(Sd.) S. F. STEWART, Deputy Secretary, Military Department.
The Medical Secretary, British Medical Association,
429, Strand, W.C.2.

Cost of National Health Insurance.

Mr. ROBERT YOUNG asked the Minister of Health whether National Health Insurance had cost since its inception £190,000,000, while benefits disbursed had only amounted to £24,000,000; and, if so, would he explain the reason for the cost of administration, and also say what was the amount of money remaining to the credit of the National Health Insurance Fund at the end of June or latest ascertainable period.—Dr. ADDISON replied: The total cost of National Health Insurance from its inception to Dec. 31st, 1919, was in round figures £190,000,000, the amounts paid in benefit and administration were £99,000,000 and £25,000,000 respectively, leaving a balance in reserve at that date of £66,000,000. The honourable Member in his figures has omitted the main cash benefits of the Act—namely, the sickness and disablement benefits.

Superannuation of Employees of Local Authorities.

Major HENDERSON asked the Minister of Health whether it was proposed to introduce a Bill this session dealing with the superannuation of employees of local authorities.—Dr. ADDISON replied: The matter to which my honourable friend refers is receiving consideration and proposals are being framed, but I cannot at present give a definite undertaking to introduce a Bill on the subject this session.

Fares of Hospital Out-Patients.

Mr. WATERSON asked the Minister of Transport if he could see his way to grant special reduced fares to people who were compelled to travel regularly to hospitals for treatment, and who now found the increased rate a terrible burden upon them.—Sir E. GEDDES replied: I regret that it is not practicable to grant reduced fares in such cases.—Mr. W. R. SMITH: Is the right honourable gentleman aware that in some of these cases it means three visits a week to a county hospital; that the very poorest people are involved; and that these high fares may be the means of depriving them of the medical treatment required to restore them to health?

Sir E. GEDDES: I have the greatest sympathy with them, but in the present financial condition of the railways I cannot think that it would be right to subsidise any particular kind of journey at the expense of the taxpayer.—Mr. WATERSO: Would the right honourable gentleman consider individual cases brought to his notice?—Sir E. GEDDES: I shall be prepared to consider any case brought to my notice, but it is extremely difficult to say where you are going to make an exception.—Mr. WATERSO: Would not a doctor's certificate justify you?—No answer was given.

TUESDAY, JULY 13TH.

Conditions of Officers in R.A.V.C.

Colonel Sir ARTHUR HOLBROOK asked the Secretary for War if any decision had yet been arrived at with regard to the conditions of half pay for officers in the Royal Army Veterinary Corps; what steps were being taken to reduce the surplus strength of major-generals in the Royal Army Veterinary Corps; and whether he was aware that there were two such officers surplus to establishment whose retention was retarding the promotion of junior officers; if the two major-generals surplus to the Royal Army Veterinary Corps establishment were paid as and reckoned on the list of colonels on the establishment of that corps; and, if so, why did they not receive similar treatment as regards the conditions of half pay as other colonels on the establishment.—Sir A. WILLIAMSON replied: The two major-generals referred to by the honourable and gallant Member were promoted substantive major-generals for distinguished service. They are not surplus to the establishment of the Royal Army Veterinary Corps, but are holding appointments as colonels, which they would have filled if they had not been promoted. Their retention is not, therefore, retarding the promotion of junior officers. I do not understand what conditions of staff pay for officers of the Royal Army Veterinary Corps the honourable and gallant Member refers to, but if he will let me have fuller details I shall be happy to look into the matter further.

Inebriate Reformatories in Scotland.

Major MACKENZIE WOOD asked the Secretary for the Home Department whether any, and what, provision had been made to enable the powers conferred by Section 24 of the Inebriates Act, 1898, to be carried out; whether a habitual drunkard might be detained in a certified inebriate reformatory for a certain time; and what certified inebriate reformatories for male patients existed in the United Kingdom.—Mr. MUNRO (Secretary for Scotland) replied: There is at present in Scotland, to which the Section cited refers, one certified inebriate reformatory to which female patients may be committed under that Section. A habitual drunkard may, on conviction under the Section, be detained in a certified inebriate reformatory for a term not exceeding three years. In Scotland no certified inebriate reformatories for male patients at present exist.

Employment of Disability Pensioners.

Major COPE asked the Minister of Labour whether he was aware that there was a large number of men being discharged from hospital with a 30 to 40 per cent. disability pension and certified as fit for light work, who were unable to find employment; and, if so, would he state what steps, if any, were being taken, or were proposed to be taken, in such cases.—Dr. MACNAMARA replied: I am aware that in a number of cases the physical disabilities of disabled men make it extremely difficult to place them in suitable employment. The National Scheme, however, depends on employers being prepared to make sacrifices in the interests of disabled men by employing men whom they might not under ordinary circumstances think physically suitable, and I hope that with the extension of the King's Roll, many of these disabled men may be absorbed into industry. I would remind my honourable and gallant friend of our schemes for training disabled men under which, up to the present, we have trained 23,640; we have in training 24,048; and on our waiting list 22,445. I would add that in the training of these men we always keep in view their prospects of employment when training is completed.

DEATH OF DR. E. W. KERR, OF DORCHESTER.—Elias William Kerr, M.D., M.Ch. Dub., M.R.C.P. Irel., has died at his residence in Dorchester, in his seventy-first year. He was the eldest son of the late Rev. W. P. Kerr, D.D., rector of Hillfield. Dr. Kerr had practised for many years in Dorchester, where he had an extensive practice, and was highly esteemed in the town and district. In 1898 he was elected a member of the Dorchester Town Council, and was later made an alderman. In 1903 he became mayor of the town. He was also chairman of the sanitary committee. During the late war, Dr. Kerr assisted the medical officer at Colliton V.A.D. Hospital, and he also rendered medical assistance at the Prisoners Camp, Poundbury.

Medical News.

UNIVERSITY OF BRISTOL.—At examinations held recently the following candidates were successful:—

FINAL EXAMINATION FOR DEGREES OF M.B., CH.B. Part II. (completing examination).—Thomas Henry Algernon Pinniger.

Part I. only.—William Harris Royal.

FINAL EXAMINATION FOR DIPLOMA IN DENTAL SURGERY. Edward James Tucker.

EXAMINATION FOR DIPLOMA IN PUBLIC HEALTH. Charles Herbert Hart, Stuart Hardy Kingston, and Arthur Denis Symons.

Part I. only.—Frederick Vaudrey Cant and Allan Dumbreck Fraser.

UNIVERSITY OF SHEFFIELD.—At examinations held recently the following candidates were successful:—

DEGREE OF M.D.

Lydia M. Henry and Lazarus Samuels.

DEGREES OF M.B., CH.B.

Final Examination.—Constance M. Chappell.

The degree of Ch.M. (ex-officio) has been conferred on the following: Percival Ellison Barber, Professor of Midwifery in the University of Sheffield; and Arthur Mayers Connell, Professor of Surgery in the University of Sheffield.

UNIVERSITY OF EDINBURGH.—At the graduation ceremonial, held in the M'Ewan Hall, Edinburgh, on July 8th, the following degrees were awarded:—

DOCTOR OF MEDICINE.

George Joseph Adams (in absentia), Peter Allan, *David Cuthbert Barron, Lawrence Dougal Callander, †Sydney Taylor Champagnon, Duncan Cook, †Thomas Frederick Corkill, *James William Edington, Harry Evans, †George William Marshall Findlay, Andrew Walker Forrest, Henry James Craig Gibson, James Gossip, Thomas Pearson Herriot, William Nicol Watson Kennedy, James Lawson, William Ashley Lethem, †David Murray Lyon, William Farquhar M'Lean, *Francis George Macnaughton, Duncan James M'Rae (in absentia), James Robertson Menzies, George Nicholson, †Edwin Douglas Pullon (in absentia), Atholl Robertson (in absentia), James Alexander Richard Thompson, Claude Bartley Tudehope (in absentia), and *William Gifford Wyllie.

* Commended for thesis. † Highly commended for thesis.

‡ Awarded Gold Medal for thesis.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

Harry Alexander, Reginald Lund Baikie, Philip Barlow, George Shuttleworth Barnett, Richard Erstine Batson, Christiana Frederik Beyers, Sam Borochowitz, Frederick George Harman Brown, Kenneth Stocks Brown, Henry Wallace Burne, Ronald M'Donald Cairns, Grace Sherwood Calver, Aidan Campbell, Helen Campbell (second-class honours), Harry Cohen, Dorothy Court, John Robert Crolius (in absentia), Montague Danziger, James Davidson, James Hamilton Dick, Margaret Laing Dobbie, Herbert John Cecil Durward (in absentia), Basil Algernon Gordon Archibald Edleston, Joseph Hayes Fairweather (second-class honours), Owen Fitzpatrick, Elizabeth Strathdee Forbes, Dora Williams Gerrard, Geoffrey M'Kay Gibson, Mary Lindsay Gilchrist, James Allan Gillison, Michael Samson Goldberg, Jessie Gordon, Janet Grant (first-class honours), Arthur William Preston Haine, John Edgar Haine (second-class honours), Arthur James Cochrane Hamilton (second-class honours), Shankar Waman Hardikar, Christina Margaret Hawick, John Paton Hope, Jacobus Petrus Immelman, William Isbister, William Kantor, Eleanor Heald Kelly, Douglas James Ackworth Kerr, Ba Kin, Sydney Levey, James Alexander Law London, Douglas Ian Otto Macanlay, James Fleming M'Conchie, Margaret Martin M'Dowall, Alexander Gordon MacGillivray, Agnes Mildred Macgown (second-class honours), Agnes Rose Macgregor (second-class honours), Henry MacKay, Florence Emily M'Kenzie, Jean Robertson Maclean, John McLeman, Jane MacLennan, Annie Sheila MacLeod (second-class honours), Jean Small Blair M'Neil, Philippus Bernardus Malherbe, Victor George Massie (in absentia), Robert M'Kie van der Merwe, Christian Balfour Fotheringham Millar (second-class honours), Christine Gardner Mitcheson, Donald John Morrison, Emily Marguerite Mure, Andrew Rowand Murray, David James Tosh Oswald, Anand Shridhar Paranjipé, William Patterson Petrie, Kenneth MacLennan Purves (first-class honours), Johannes Christian Rabie, Charles Barclay Reekie, Ruth Jean Deans Ritchie, Hera Ross, Annie May Roxburgh, Charles Wellwood Rubidge, Louie Antoinette Rubidge, Helen May Russell, Henry John Edward Schultz, Thomas Scott, Charles Shapiro, George Alexander Sinclair, William Arnold Sinclair, Philip Bradley Smale, Alice Barbara Stewart Smith, Dorothy Mary Smith, Thomas Sprunt (second-class honours), Ian Maclaren Thompson, Henry Thomson, Mabel Thomson, *Marjorie Thomson (in absentia), David Livingstone M'Rae Tod, John Calvin Truter, Thomas Cleave Wakefield, Grace Walker, Edith Grace Wilkes, Apolina Anderson Wilson, and James MacLaren Young (second-class honours).

BACHELOR OF SCIENCE.

Department of Public Health.

Thomas Campion Lauder (in absentia).

DIPLOMA IN PUBLIC HEALTH.

George Arthur Borthwick, George Campbell (in absentia), John Dick, George Francis Palmer Heathcote, Wilhelmina Weir Hendry, Mary Pringle Hislop, Alexander John Pollock, Francis Benjamin Sutherland, and James Munro Tyrrell.

The following awards were also made:—

Faculty of Medicine.—Thesis Gold Medallists: George William Marshall Findlay, David Murray Lyon, and Edwin Douglas Pullon. Cameron Prize in Practical Therapeutics: Sir Robert Jones, K.B.E., C.B. Ellis Prize in Physiology: Robert John Stewart M'Dowall. Gunning Victoria Jubilee Prize in Materia Medica: Francis George Macnaughton. Ettles Scholarship and Leslie Gold Medal: Andrew Weir Davison. Allan Fellowship in Clinical Medicine and Clinical Surgery: Agnes Rose Macgregor. Freeland Barbour Fellowship: Helen Campbell, M.B., Ch.B. M'Cosh Graduate's and Medical Bursaries: David Livingstone M'Rae Tod. Beane Prize in Anatomy and Surgery: Arthur James Cochrane Hamilton. Mouat Scholarship in the Practice of Physic: Henry Wallace Burne. Conan Doyle Prize: Sydney Levey. Annandale Gold Medal in Clinical Surgery: Arthur James Cochrane Hamilton. Buchanan Scholarship in Gynecology: Janet Grant. James Scott Scholarship in Midwifery: Douglas Alexander Miller. Scottish Association for Medical Education of Women Prize: Janet Grant. Dorothy Gilliland Memorial Prize: Janet Grant. Wellcome Medals in the History of Medicine: *Gold Medal*, Adam Cairns White; *Silver Medal*, Hilda Marion Davis. Pattison Prize in Clinical Surgery: John Murray Black. Wightman Prize in Clinical Medicine: Thomas Ferguson. Cunningham Memorial Medal and Prize in Anatomy: John Gray. Whiteside Bruce Bursary: Rennie Cooksey Burton and Margaret Christine Tod (equal).

UNIVERSITY OF ABERDEEN.—The summer graduation ceremony was held on July 8th, when the following degrees were conferred:—

DOCTOR OF MEDICINE.

Ernest William Henderson Cruickshank (honours for thesis), Hugh Ross Souper (honours), James George Copland, and John Lewis Menzies.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY.

*Annie Anderson, Emily Mary Badenoch, Isobel Campbell Brown, Enid Calder, Margaret Winifred Calder, Gertrude Elizabeth Cormack, Alan Alexander Duffus, John Bright Duguid, John Grant Elmslie, Vivian Leslie Ferguson George Matthew Fyfe, George Milne Gray, *James Christian Hall, Alexander Hastings, Robina Inkster, Helen Margaret Jardine, *Gertrude Helen Lendrum (second-class honours), Horatio David Low, †John Douglas McLaggan, *Annie Elizabeth Melvin, Matilda Fisher Menzies, *Marjory Mary Milne, *John Henry Mulligan (second-class honours), Frederic Dudley Ross-Key, Alisdair McIntyre Smith, Daniel Ironside Walker, Hiap Tock Wee, and Hilda Sutherland Young.

* Passed Final Professional Examination with distinction.
† Passed Final Professional Examination with much distinction.
The John Murray medal and scholarship were awarded to Dr. Young Garden Murray.

DIPLOMA IN PUBLIC HEALTH.

Alfred William Harper Cheyne, Edward James Clark, George William Elder, Thomas William Edward Elliott, Alexander Fowle Fraser, George Alexander Connell Gordon, Alexander Johnstone, Sydney Walker Lund, Maggie Florence Jane Moir, John Skinner, James Lind Smith, John Herbert Stephen, John William Stephen, William Taylor, James Williamson Tocher, Burton Yule, and Vincent Thomas Borthwick Yule.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE, SCHOOL OF PHYSIC.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I., *Materia Medica and Therapeutics; Jurisprudence and Hygiene; Pathology and Bacteriology.*—Isak George Sacks (high marks), Charles Theodore de Mornet Villet (high marks), Theunis de Bruijn, Olive Victoria Fair and Jacob Hofman (equal), Robert Evatt Faussett, Max Elion, Isaac Cornick, Alice Elizabeth Lawlor, May Evelyn Powell, Abraham Agranat, Ruth Florence Flavell, Gilbert Kirker, and Alida Charlotte Burt.

Pathology only (Completing Examination).—Patrick Joseph Healy and Alfred Henry Norman Todd and Thomas Gerald Warham (equal), and John Douglas Thompson.

Part II., *Medicine.*—Eric Henry Cooke Allen (high marks), Maurice Nurrock (high marks), William James Alexander Russell, Janie Millar Cummins, Olive Baile, Frederick Ziervogel van der Merwe, Eileen Hilda Dowse, Doris Louisa Graham, Essie Stuart Smyth, William Burton Fox, Edward Haslett Frazer, Johannes Cornelius Coetzee, Frederik Wynand Pienaar, William Richard Burns, and Frederick William Shegog.

Surgery.—Eric Henry Cooke Allen and William Theodore Micks (equal, high marks), Herbert Victor Exner and Francis Victor Small (equal, high marks), Adrian Johannes Louw Snyman and Frederick Ziervogel van der Merwe (equal, high marks), John Henry Brewell Crosbie, William James Alexander Russell, Philip Jabkovitz, Johannes Cornelius Coetzee, Edward Haslett Frazer, Johannes Philippus de Villiers, Moira Mary Brown, William Bernard Joseph Pemberton, Joseph Ballantyne Maguire, Bernard Moshal, Mervyn Edmund McBrien, and Frederik Wynand Pienaar.

Midwifery.—Elinor Dorothy Stopford, Thomas Falkland Litton Cary, William Bruce Briggs and Frederick William Shegog (equal), Charles William Parr, Francis Young Pratt, Edmund Cecil Smith, James Daly Leahy, Percival Israel Levitt, Frederick Wynand Pienaar and Richard Wood Power (equal), Donald Victor Latham, Mervyn Edmund McBrien and Constance McIlraith (equal), Nora Griffith, Patrick Joseph Healy, David John Browne, and James Alexander Smith.

MASTER IN SURGERY.

Isaac Whitla Corkey.

DIPLOMA IN PUBLIC HEALTH.

Part I., *Bacteriology, Chemistry, Physics, and Meteorology.*—Anna Mary Kathleen O'Halloran, Rupert Montgomery Gordon, Edward Lipman, Joseph Patrick Quinn, Eileen Gertrude Gwynn, James Wilfred McKinney, and Jessie Gilbert and Richard Edward Tottenham (equal).

Part II., *Sanitary Engineering, Sanitary Inspection, and Report; Hygiene, Epidemiology; Vital Statistics; Public Health Law.*—Charles Henry Comerford, Patrick Rock, Matthew Joseph Graham, Alfred Henry Price, John Francis Gaha, Rupert Montgomery Gordon and James Wilfred McKinney (equal), Richard Edward Tottenham, Charles Edward Pengelly, and Carlile Kelly.

QUEEN'S UNIVERSITY OF BELFAST.—Of the 66 candidates—the largest number on record—who presented themselves last week for the Final M.B. of the Queen's University of Belfast, 52 passed. Mr. James S. Lee was first in medicine, Mr. F. M. B. Allen was first in surgery (Mr. James P. Martin was also awarded a special prize), and Mr. C. L. Broomhead was first in midwifery. Each of these first prizes in the main groups of medicine, surgery, and midwifery, is of the value of £30. Mr. Broomhead and Mr. Allen divided a prize of £20, being equal as first in all the subjects combined.

UNIVERSITY OF LIVERPOOL.—At recent examinations for the Diploma in Public Health the following candidates were successful:—F. A. Belam, J. Cullen, Constance M. Edwards, A. V. Glendenning, H. Middleton, S. R. Richardson, R. Rimmer, A. A. Turner, and J. Walker.

UNIVERSITY OF BIRMINGHAM.—The Degree Congregation was this year held in the Great Hall of the University on July 10th for the first time since 1914. In the intervening years the University formed the 1st Southern General Hospital with 1600 beds, and the Great Hall itself became the largest ward in England. The degrees were conferred by Sir Gilbert Barling, the Vice-Chancellor; 16 men and women were presented for the degrees of M.B., Ch.B., one man received the M.S., and one woman the M.D.

An elaborate scheme for post-graduate lectures to occupy a fortnight, beginning July 5th, had been arranged, but unfortunately the response was unsatisfactory, and for several of the sections the number of applications was too small to justify the holding of the lectures. Few practitioners were found able to give up the time necessary and the season was probably also unsuitable. The applications for the Sections of Medicine, Diseases of Children, Physiology, Radiology and Electrical Treatment, however, enabled these to be proceeded with. In the Section of Medicine Dr. O. J. Kauffmann gave lectures and demonstrations on the Diagnosis of Nervous Diseases, Dr. W. H. Wynn on the Diagnosis and Treatment of Pulmonary Tuberculosis, Drs. J. G. Emanuel and K. D. Wilkinson on Modern Methods in Heart Disease. The Section of Diseases of Children was conducted by Dr. Douglas Stanley, Dr. L. G. Parsons, and Mr. Bertram Lloyd. Professor E. W. Carlier discussed certain problems of Internal Secretion in the Section of Physiology, and Dr. H. Black gave a series of demonstrations on Radiology.

THE Royal Statistical Society has opened a register of the names of persons eligible for statistical posts. The society has often been asked to recommend qualified statisticians and has taken this means of bringing those who have appointments to offer into touch with suitable applicants. A list of names and qualifications will be furnished on application to the Secretary, at 9, Adelphi-terrace, London, W.C.2.

MINISTRY OF PENSIONS: HONORARY CONSULTANTS.—The following physicians and surgeons, in addition to those whose names have already been announced, have consented to act as honorary consultants to the Ministry of Pensions:—

Honorary Consultants in Cardio-vascular Cases.

J. E. McIlwaine, M.D., R.U.I., D.P.H., Ulster Region.
H. J. Starling, M.D. Lond., D.P.H., Eastern Region.
Carey Franklin Coombs, M.D. Lond., F.R.C.P., S. Western Region.
T. Wardrop Griffith, M.D. Aberd., F.R.C.P., Yorkshire Region.
Wm. Errington Hume, M.D. Camb., F.R.C.P., Northern Region.
John Hay, M.D. Vict., F.R.C.P., North-Western Region.
Dr. Thos. Mather Thomson, L.R.C.P. & S.I., Ireland South Region.
William Thos. Ritchie, M.D. Edin., F.R.C.P., Eastern Portion of Scotland Region.
John M. Cowan, M.D. Camb., D.Sc. Glasg., Western Portion of Scotland Region.

Honorary Consultants.

Sir James Dundas Grant, F.R.C.S. Eng., Honorary Consultant in Aural Diseases to the Ministry.
Hugh Maclean, M.D. Aberd., D.Sc. Lond., Honorary Consulting Physician to the Ministry.
Sir Robert W. Philip, M.D., F.R.C.P. Edin., Honorary Consulting Physician in Tuberculosis to the Ministry.
Chas. J. Bond, F.R.C.S. Eng., Honorary Consulting Surgeon in East Midland Region.
Astley Vavasour Clarke, M.D. Camb., Honorary Consulting Physician in East Midland Region.
Sir Arthur Chance, F.R.C.S.I., Honorary Consulting Surgeon, Ireland, South Region.
William Richard Dawson, M.D. Dub., F.R.C.P.I., Honorary Consultant on Functional Nervous and Mental Cases for Ireland.
Francis Carmichael Purser, M.D. Dub., F.R.C.P.I., Honorary Consultant on Organic Neurological Cases for Ireland.

THE Sir Alfred Jones Laboratories, Pembroke-place, Liverpool, under the direction of the Liverpool School of Tropical Medicine, will be officially opened by Lord Leverhulme on Saturday, July 24th, at 2.30 P.M.

Mansfield House University Settlement, Barking-road, Canning Town, London, E.16, is again open to receive as residents men who are prepared to devote time to social studies and activities.

THE fifty-seventh annual general meeting of the British Pharmaceutical Conference will be held at Liverpool from Monday next, July 19th, until the following Friday. Mr. C. A. Hill, B.Sc., Managing Director of the British Drug Houses, will preside, and will deliver an address on Progress in Science and Pharmacy, while an interesting list of scientific communications is announced.

Surgeon-Major J. K. Goodwin, A.M.D. (retired), died at his residence, Newton Abbot, Devon, on June 14th, in his 90th year. The deceased officer, who qualified in 1855, served through the China campaign (1860) and the New Zealand campaign (1862). He retired from the Service in 1876.

DONATIONS AND BEQUESTS.—By will the late Sir John Thomas, of Brook House, Woburn, Bucks, left, among other bequests, £1000 each to the London Temperance Hospital, the High Wycombe and Earl Beaconsfield Memorial Hospital, and the Marlow Cottage Hospital.

Dr. Noel Dean Bardswell has been awarded the Bronze Médaille de la Reconnaissance Française by the French Red Cross for his services in advising the French Government in regard to the treatment of tuberculosis in the French soldier, and more particularly in connexion with the establishment of the Sanatorium Training Colony at Sillery, in the South of Paris.

REGISTRAR OF NURSES.—The Minister of Health has sanctioned the appointment by the General Nursing Council (established under the Nurses Registration Act, 1919, to form and keep a Register of Nurses for the Sick) of Miss Marian Scott Riddell, R.R.C., to be the Registrar of the Council. Miss Riddell, who was trained at St. Bartholomew's Hospital, was before the war matron of the Chelsea Hospital for Women. During the war she served as matron of the 2nd London General Hospital, and subsequently of the 53rd General Hospital in France, until she was appointed principal matron and afterwards Acting Matron-in-Chief of the Territorial Force Nursing Service.

BIRMINGHAM GENERAL HOSPITAL.—The financial position is causing much anxiety. In order to pay off a large overdraft at the bank the board of management, after much consideration, have recommended to the governors that securities be sold to realise a sum of £50,000. In addition they have decided to recommend that a maintenance charge be required from patients after Jan. 1st, 1921. The charge for in-patients over 12 years of age would be one guinea per week, and under 12 half-a-guinea a week. A reduction may be allowed in cases of patients staying for a less period than a week, and part or all of the charge may be remitted in case of necessitous patients.

VENEREAL DISEASES AMONG SEAMEN.—The International Labour Conference at Genoa has given attention to some aspects of the health of seamen, and notably the question of the prevention and treatment of venereal diseases. The delegates (who represent the Governments, shipowners, and seamen of a score of countries) were invited by Mrs. A. C. Gotto and Dr. Otto May, representatives of the National Council for Combating Venereal Disease, to attend a meeting on the question of combating venereal diseases in the Mercantile Marine. At this meeting the hope was expressed that the Conference would not disperse without taking some definite action to help on the work of fighting these diseases, and the following resolution was framed and submitted to the Conference:—

"The International Seamen's Conference, recognising the importance of taking active international measures for the prevention and treatment of venereal diseases in the Mercantile Marine, desires to urge upon the Health Section of the League of Nations the need for immediate attention to this subject. They would recommend for special consideration: (1) The provision of adequate facilities for the prevention and treatment of venereal diseases at all the principal ports; (2) the inclusion of venereal diseases among the conditions for which free drugs and treatment are provided for members of the Mercantile Marine; (3) the dissemination of appropriate information on the subject to seafarers, especially to those at training establishments; and (4) the provision of adequate facilities for recreation at all large ports under the administration of joint organisations representative of owners and seafarers. They desire in addition to call special attention of the international labour organisations to the importance of No. 4 about facilities for recreation."

According to an unofficial report this resolution was adopted by the Conference.

VENEREAL DISEASE IN ABERDEENSHIRE.—At a meeting of the Sanatorium Benefit and Venereal Disease Committee of the Aberdeen County Council held on July 8th the medical officer of health reported that the cases of venereal disease treated had been greatly increasing. The out-patients in the first year of the scheme, 1917-18, for the city and the county, had been 197. The next year the total was 383, and last year 738. The in-patients were the same, the accommodation being in full use. Regarding the suggested provision of out-patient venereal treatment at Peterhead and Fraserburgh the medical practitioners were of opinion that treatment centres there would not be used. The patients would prefer to go to the Aberdeen centre, where they were not known.

AMALGAMATION OF DENTAL SERVICE AT BRIGHTON.—It has been decided that there should be an amalgamation of the Brighton, Hove, and Preston Dental Hospital and the Brighton and District Dental Service; this amalgamation was carried out on July 1st. The Dental Hospital was established in 1886 and the Public Dental Service in 1907. The amalgamation was arranged with the object of extending the privileges on a much larger scale both to the necessitous poor and to those who are able to pay a small fee. A great saving of administrative expenditure as well as of time will, it is claimed, be effected by the amalgamation, and also a great deal of the time of those who give their services gratuitously, and those who carry out the full range of dental surgery at a very small fee. It is interesting to note that X ray photography and the pathological side of dental surgery are to be encouraged. The progress of dental work under this new scheme will be watched with great interest.

POST-GRADUATE WORK IN LONDON.—A considerable amount of post-graduate work has been arranged in London during the summer months, and within the next few weeks additional announcements are likely to come to hand. At the National Hospital for Diseases of the Heart a course covering two weeks will be held from Monday, July 19th, to Saturday, July 31st. Work will commence each morning at 10 o'clock, the first session being devoted to practical instruction in graphic methods (including the polygraph and electrocardiograph); at 11.15 laboratory and clinical demonstrations will be given illustrating the physiology, pathology, and therapeutics of the heart and circulation; clinical work in the wards and out-patient department will occupy the afternoon, and a daily lecture will be delivered at 5 o'clock. The number of entries for this course is limited, and the roll is now almost complete. Immediate application for the remaining tickets should be made to the Secretary of the Fellowship of Medicine, who will give all information as to the fees for the course.

The North-East London Post-Graduate College (Prince of Wales's Hospital, Tottenham) has arranged, in conjunction with the Fellowship of Medicine, an intensive course during the same period, which covers the various departments of medicine and surgery. Demonstrations will be given each day at 10.30 A.M., 11.45 A.M., 2 P.M., and 3 P.M., whilst a lecture will be delivered at 4.30 P.M. Luncheon will be obtainable in the neighbourhood of the hospital, and tea will be provided at 4 P.M. Graduates who desire to attend this course are asked to send in their names without delay to the Secretary of the Fellowship of Medicine, who will forward the necessary information as to the fees for the course, together with a complete syllabus of the demonstrations and lectures. The afternoon lectures are open to all qualified practitioners without fee.

Courses of lectures are now being given at the London Hospital and the Cancer Hospital. In the clinical theatre of the London Hospital Medical College Dr. Theodore Thompson and Dr. George Riddoch are giving a course of Neurology on the Tuesdays and Wednesdays in July and August at 2 P.M., the final lecture being given on August 18th. At the Cancer Hospital a course of clinical lectures on the Diagnosis and Treatment of Cancer is being given on the Tuesdays and Fridays in July and August at 4.30 P.M. In gynaecology Mr. Victor Bonney has resumed his "Talks on Gynaecology" at Middlesex Hospital each Saturday morning at 10.30 during July and August. The Wednesday afternoon lectures at Queen Charlotte's Hospital come to an end on July 28th.

For September a course of Proctology is being arranged at St. Mark's Hospital, City-road, and the postponed course on Spa Treatment will take place at Bath in the third week of September. Early application should be made to the secretary for tickets. The *Bulletin* of the Fellowship of Medicine contains the detailed syllabus of these courses, together with an extensive list of daily hospital appointments open to members of the Fellowship of Medicine. Graduates who intend to devote any portion of their time to study in London are invited to communicate with the Secretary of the Fellowship of Medicine, 1, Wimpole-street, W.1, stating the class of work in which they are most interested.

PRESENTATIONS TO MEDICAL MEN.—**Dr. H. Pattison** Armstrong, police doctor at Kingston-on-Thames, has been presented with a gold stop-watch by the directors of the Anglo-American Oil Company for an attempt to save the life of Francis Walker, one of their employees. Walker was employed at the Kingston dépôt and became overpowered by petrol fumes when working in a large storage tank. The foreman of the works had already made an unsuccessful effort to rescue Walker when Dr. Armstrong entered the tank and succeeded in placing a rope round him. He was hauled to the top alive but died shortly afterwards. —At a public meeting recently held at Frome, Somerset, Dr. J. M. Rattray was presented with a cheque for 100 guineas, raised by public subscription, as a mark of respect, on the occasion of his leaving the town after 38 years' residence.

ROWETT RESEARCH INSTITUTE AT CRAIBSTON.—Mr. John Quiller Rowett, who has given the munificent donation of £10,000 to the Institute for Research on Animal Nutrition at Aberdeen, was entertained at lunch on July 9th by the joint committee representing Aberdeen University and the North of Scotland College of Agriculture, which is in charge of the institute. In the absence of the principal, Sir George Adam Smith, Professor J. A. MacWilliam presided, and, in proposing the health of Mr. Rowett, remarked that they were witnessing the beginning of a scheme of the utmost promise. While the work of the institute related primarily to the nutrition of animals, the whole physical growth and well-being of man was intimately connected with the question of nutrition. It was in experimental work and in throwing light on the intricate problems of the proper feeding of human beings, especially of children, that the institute was destined to play such a great and fruitful part. Mr. Rowett, in reply, congratulated the University on having secured the services of two such brilliant investigators as Dr. J. B. Orr and Dr. Plimmer as director and chief biochemist respectively.

Appointments.

ALDERSON, G. G., F.R.C.S., has been appointed an Honorary Surgeon of the Warneford General Hospital, Leamington, Spa. **BRYAN, C. W. G., M.C., F.R.C.S.**, Surgeon in charge of out-patients (additional), and in charge of the Orthopaedic Department, St. Mary's Hospital. **DAVIDSON, MAURICE, M.D. Oxon., M.R.C.P. Lond.**, Honorary Physician to the Miller General Hospital for South-East London. **ROTH, P. B., F.R.C.S. Eng.**, Orthopaedic Surgeon, Miller General Hospital, Greenwich. The Hospital for Sick Children, Great Ormond-street: **PATERSON, DONALD H., B.A., M.B., Ch.B.**, Medical Registrar and Pathologist; **BOND, CHARLES E., M.B., M.R.C.S., L.R.C.P.**, Casualty Medical Officer.

Vacancies.

Births, Marriages, and Deaths.

BIRTHS.

CHANDLER.—On July 12th, the wife of F. G. Chandler, M.A., M.D. Cantab., M.R.C.P., of Harley-street, W., of a daughter. **CLARK-KENNEDY**.—On July 5th, the wife of A. E. Clark-Kennedy, M.R.C.S., of Corpus Christi College and Bateman-street, Cambridge, of a daughter. **SCOTT**.—On July 11th, at 5, Marion-crescent, Selkirk, the wife of Major T. H. Scott, D.S.O., M.C., R.A.M.C., of a son.

MARRIAGES.

BARLOW-MACDOUGALL.—On July 8th, at St. Mary-in-the-Castle, Hastings, Henry Percy Barlow, M.B., Parkstone, Dorset, to Adelaide Isabella, daughter of the late A. MacDougall, Edinburgh. **HUTCHINSON-KER**.—On July 8th, at St. Stephen's, Ealing, Lieut. Charles A. Hutchinson, R.A.M.C., to Elsie Norah, third daughter of Mr. and Mrs. R. L. Ker, Amherst-avenue, Ealing. **LIVINGSTON-LEGASSICKE-CRESPIN**.—On July 8th, at St. Mary Abbot's, Kensington, Flight-Lieut. Philip Clermont Livingston, R.A.F., M.S., B.A. Cantab., M.R.C.S., D.P.H., to Lorna Muriel, only daughter of Mr. and Mrs. Legassicke-Crespin, late of West Cromwell-road, Kensington, and Modbury, Devon. **MURPHY FETHERSTONHAUGH-FRAMPTON**.—On July 8th, Major Leo Murphy, D.S.O., R.A.M.C., to Millicent, daughter of Mr. and Mrs. Fetherstonhaugh-Frampton, of Moreton, Dorset.

DEATHS.

BERNARD.—On July 10th, at Sydenham-road, Bristol, David Edward Bernard, M.R.C.S., L.R.C.P., aged 78. **DICK**.—On July 12th, at Bembridge, Isle of Wight, Inspector-General of Hospitals and Fleets Sir James Nicholas Dick, K.C.B., R.N., Honorary Surgeon to the King, aged 89. **REINHARD-RTLAND**.—On July 8th, at Weymouth-street, Charles Emmanuel Reinhard-Rutland, M.D. **N.B.**—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

A Course of Twelve Lectures on Neurology, open to Students and Graduates of the London Hospital and other Schools—

TUESDAY, July 20th.—2 P.M., Lecture III.—Mr. Riddoch: Disorders of Function from Lesions of the Cerebellum and its Connexions.

WEDNESDAY.—2 P.M., Lecture IV.—Dr. Thompson: Varieties of Cerebellar Disease.

SURGICAL UNIT, in the Units' Lecture Theatre, London Hospital, E.

Special Course of Lectures open to both Students and Post-Graduates.

Two Lectures on Coli Infection of the Kidney—

WEDNESDAY, July 21st.—4 P.M., Lecture II.—Mr. F. Kidd.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 19th.—2 P.M., Mr. D. Armour: Operations. 2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

TUESDAY.—10 A.M., Dr. Robinson: Gynaecological Operations. 2.30 P.M., Mr. T. Gray: Operations.

WEDNESDAY.—2 P.M., Mr. D. Armour: Visit to Surgical Wards. 2.30 P.M., Mr. Addison: Operations.

THURSDAY.—2 P.M., Mr. D. Armour: Operations. 2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

FRIDAY.—10 A.M., Dr. Robinson: Gynaecological Operations. 2.30 P.M., Mr. T. Gray: Operations.

Daily.—10 A.M., Ward Visits. 2 P.M., In-patient Clinics and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 19th.—10.30 A.M., Mr. J. H. Evans: Cystoscopy. 11.45 A.M., Dr. Whiting: Graphic Method of Studying Heart Disease. 2 P.M., Dr. Sundell: Diseases of Ductless Glands.

3 P.M., General Hospital Work. 4.30 P.M., Lecture.—Dr. R. Hutchison: Abdominal Pain and its Diagnostic Significance.

TUESDAY.—10.30 A.M., Mr. Benians: Blood Changes in Disease. 11.45 A.M., Mr. N. Fleming: Injuries of the Eye. 2 P.M., Dr. R. M. Leslie: Cases of Lung Disease. 3 P.M., General Hospital Work. 4.30 P.M., Lecture.—Dr. R. M. Leslie: The Role of Endocrine Glands in Health and Disease.

WEDNESDAY.—10.30 A.M., Dr. Alexander: Investigation of Dyspeptic Conditions. 11.45 A.M., Mr. Carson: After-Treatment of Abdominal Operations (uncomplicated). 2 P.M., Mr. J. H. Evans: Diseases of the Breast. 3 P.M., General Hospital Work. 4.30 P.M., Lecture.—Dr. A. F. Hurst: Nature and Treatment of Hysteria.

THURSDAY.—10.30 A.M., Mr. Hayton: Laryngoscopy and Rhinoscopy. 11.45 A.M., Mr. N. Fleming: Refraction of the Eye. 2 P.M., Dr. Metcalfe: Treatment of Lupus by X Rays. 4.30 P.M., Clinical Consultations (Obscure Medical Cases).

FRIDAY.—10.30 A.M., Mr. Benians: Cellular Exudate in Gonorrhoea. 11.45 A.M., Dr. Whiting: Graphic Method of Studying Heart Disease. 2.30 P.M., Dr. Leslie: Auscultation of the Lungs, Common Fallacies. 3 P.M., General Hospital Work. 4.30 P.M., Lecture.—Mr. H. D. Gillies: Plastic Surgery of the Face and its Application to Civil Conditions.

SATURDAY.—11 A.M., Dr. Macarthur (at the L.C.C. Mental Hospital, New Southgate): Cases of General Paralysis

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, July 19th, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhoea by Electrolysis.

CANCER HOSPITAL, Fulham-road, S.W.

Clinical Lectures on the Diagnosis and Treatment of Cancer.

TUESDAY, July 20th.—4.30 P.M., Mr. W. E. Miles: Cancer of the Rectum.

FRIDAY.—4.30 P.M., Dr. R. Knox: X Rays in Cancer of the Alimentary Tract.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street (behind Whitworth Park).

THURSDAY, July 22nd.—4.30 P.M., Dr. A. C. Magian: Chronic Uterine Complaints.

Notes, Short Comments, and Answers to Correspondents.

A SURGEON AND AN EX-EMPEROR.

THE letters of William Warden, surgeon on Board H.M.S. *Northumberland*, the ship which conveyed Napoleon to St. Helena, were published in 1816 and went through more than one edition. Many medical men may be familiar with them, but they are generally cited as a contemporary record of certain phases in the earlier period of Napoleon's captivity, rather than for the glimpses which they give of British medical practice 100 years ago, as seen by a surgeon in the Royal Navy, and an "intelligent foreigner." The questions which Napoleon, as a strategist, a military organiser, and a politician, showered upon those officers with whom he was brought in contact during the *Northumberland's* voyage, were no doubt, as Mr. Warden affirms, directed to those who could best give the information asked for, and in the best manner for extracting it. Those which he asked of a medical man to whom he evidently had taken a fancy show him as rising indeed above the level of a Count Smolitorck, but hardly as a man of acute intelligence mastering rapidly the essentials of the subject of his inquiry. In fact, he laid down the law and cross-questioned Warden about as comprehensively and with no greater acumen than the average exalted personage or layman successful in his own walk of life, whom chance brings into contact with a medical man unable to escape from him. "In the course of your practice and on your conscience, how many patients have you killed?" and, in discussing the merits of a drug which he had denounced as a "bad medicine," "Did Hippocrates use it?" are hardly the questions of a master mind, although the first was put "with a half-comic, half-serious countenance," and the latter was not difficult to answer. In reply, Mr. Warden was able to say politely, if platonically, that his conscience did not accuse him of having caused the death of anyone, and with regard to Hippocrates, that although he was, as Napoleon put it, among the first physicians, he "might have derived great advantages from modern discoveries"—courteous replies to an exalted personage. Napoleon, however, did not always ask absurd questions, and as he no doubt had often tried to pick the brains of eminent French doctors as pertinaciously as he did in the case of the ordinary Englishman with whom fate had brought him into contact, he presumably had learnt to voice their opinions. In the conversation into which he introduced Hippocrates he was questioning Warden's desire to treat General Gourgon's dysentery with mercury, and he put the case for non-intervention not unreasonably. "Does not nature endeavour to expel morbid matter, and may not the present painful struggle be an effort of nature to rid herself of what is obnoxious?" Warden was also not unreasonable in his reply: "I have been taught to assist nature."

Blood-letting: A British Panacea.

The ex-Emperor was constantly twitting Warden on the subject of the British fondness for blood-letting, although he stated on one occasion that when his Empress was confined he had himself suggested bleeding her, as "she was in a very full habit." Dr. Corvesart, who was attending her, and in whom he had evidently great confidence, had refused, and no doubt expressed views held by other Frenchmen as to the British panacea. Warden staunchly, and perhaps patriotically, upheld the efficacy of bleeding, citing as conclusive a case from his own experience, which might almost be described as awe-inspiring. At any rate, he does not record any retort from his hearer, and concludes by saying that it was "enough to make anyone a convert to the lancet." He had, he said, on one occasion in three days reduced the pulse of a seaman sick with "an inflammation of the stomach" from 150 beats in the minute to 87, taking from him in the time mentioned 15 lb. of blood. The story, at any rate, must have impressed on his hearers the stalwart physique of the victors of the Nile and Trafalgar.

Comparisons between French and English Surgeons.

If Warden's replies when dealing with the causes and treatment of disease serve to illustrate the progress of a century in science, some of those upon more general topics connected with medicine might have been given *mutatis mutandis* to-day to any "intelligent foreigner." By this it is not intended to suggest that the distinctions drawn by Warden between British and French surgery would be couched in the same terms as in 1816, but merely that the principles of comparison would be the same. At any rate, the honourable aims and standards of British medicine have remained the same for 100 years, and Warden showed himself a sensible, level-headed man, properly jealous of the honour of his profession.

"Which do you think are the best surgeons, the French or the English?" Napoleon inquired. "The English, undoubtedly."

"But wherefore?"—"Because our schools are better. There is more system in our education, and the examination is such as to establish the fitness of any candidate for the profession before he is regularly admitted into it."

"But in point of practice will you not allow that the French surgeons have the advantage of you?"—"In practice, General, the French are empirics. Though they do not vend nostrums like our quacks in England. They are, in fact, more guided by experience than theory. But you, Sir, have enabled my brethren in the English army to be tolerable proficient in field practice."

Napoleon smiled, and changed the subject, still intent upon comparisons.

"Who is your first physician in London?"—"That is an inquiry which I did not expect and cannot take upon myself to answer; there are so many physicians of eminence there that it would be hazardous to mention a favourite name."

"But have you no particular person in the profession who takes the lead?"—"No, indeed; there are, it is true, fashionable physicians who have their run for a season or two, or even three, but I could not give the preference to one without doing injustice to fifty. I could, I think, more particularly distinguish eminent surgeons."

"What is the general fee?"—"That frequently depends upon the rank and fortune of the patient."

"What is the highest you have ever known?"

Warden was cautious in his answers as to medical fees and medical fortunes, and the ex-Emperor seems to have asked the question in order to introduce the statement that Corvesart had received 3000 napoleons for attending the Empress Maria Louisa in her confinement.

Warden's Remuneration.

The subject then was changed abruptly to Warden's own practice and position. Was he employed on shore, as well as at sea? And did he receive good fees when he visited the patient of a friend? As to this last he answered, "I have never yet accepted of a fee. While I serve I am satisfied with my pay." He was a worthy man indeed, with a contented soul, for his pay at that time, as he told his questioner, was but £220 per annum after 20 years' service in the navy. Moreover, at St. Helena living was not cheap. "A stranger cannot board under 30s. a day." So he made both ends meet by accepting the hospitality of his friends and having some of his meals on board the *Northumberland*. He admitted that his navy pay was small, but declared that he had no right to complain, as he knew the conditions of service before he engaged, and in England there was no compulsion to serve. So he went on placidly to explain where he was educated, citing to Napoleon the names of Black, Munro, and Gregory as eminent names in medical education at Edinburgh, with the reservation that he could name equally eminent teachers in England. Napoleon had strong views of his own, needless to say, on the comparative merit of his own medical advisers. "I never knew," he said, "but one physician who was infallible in his diagnostics. He was certain in his discovery of the nature and seat of a disease; his name was Dubos; but strange to say, he could not prescribe; and consequently would never undertake the treatment or cure of a complaint whose character his acumen could so accurately penetrate." It was soon after this interview that Warden left St. Helena, with a prospect of some day retiring on a pension of 6s. a day, to be increased only if he should then have served for 30 years.

SPECIAL PENSIONS GRANTS.

THE regulations of the Special Grants Committee of the Ministry of Pensions have been extended and revised, and the Committee is now in a position to consider applications from—

1. Officers disabled in the war (a) in respect of their wives, up to a maximum of £50 a year; (b) in respect of their children up to a maximum of £36 per annum for each child.
2. The widows and dependents of deceased officers.
3. Nurses belonging to the Imperial Military or other nursing services, who served in the war.

These regulations will shortly be on sale at H.M. Stationery Office, price 1d. Claims should be addressed to the Secretary, Special Grants Committee (Officers Section), Millbank House, London, S.W. 1.

ROYAL UNITED HOSPITAL, BATH.

A REPRESENTATIVE meeting was recently convened by the Mayor of Bath to consider the serious financial position of the Royal United Hospital. After some discussion it was eventually decided to build an institution at Combe Park, on the site of the present Pensions Hospital. It is proposed first to establish wards for persons of limited means, who will pay moderate fees, and ultimately it is hoped to remove the whole hospital from its present position in the centre of the city to Combe Park. The entire scheme will involve an expenditure of about £148,000. Mr. F. Mallett has promised to purchase the site, which will cost £5000. Promises of amounts totalling £20,000 have already been received towards the scheme.

SANITARY ADMINISTRATION IN THE PUNJAB, 1918.

THE population of the Punjab at the 1911 census was 19,337,146, and for the year 1918 was estimated at 20,205,141. Calculated on this total, the birth-rate was 37.9, and the death-rate 77.5 per 1000; if estimated on the census figures these ratios would be 39.6 and 81 per 1000 respectively. The birth-rate (39.6) was considerably below that for the preceding quinquennium (45.2), but higher than that in the neighbouring North-West Frontier Province (30.58), and in Madras (28.89), as well as in many other provinces, during 1918. There was very great variation in the ratios for different districts. Thus in Karnal there were 51.3, and in Rohtak 49.2 births per 1000, while in Simla the ratio was only 21.2, and in Dera Ghazi Khan 19.3. The death-rate was for the whole province 81 per 1000, the total number of deaths being 1,565,560. This mortality ratio is the highest recorded in the Punjab since 1867, the excess being due entirely to influenza, recorded under the head of fevers. Lieutenant-Colonel W. H. C. Forster, I.M.S., Sanitary Commissioner for the province, who presents this report, gives a detailed and graphic account of the visitation, which, he states, was the worst epidemic that the Punjab has ever experienced, and—

“one which, with almost diabolical malignancy, selected young adults for its victims. A peculiarly fatal type of pneumonia appeared as a concomitant of the disease, and from Oct. 15th to Nov. 8th the state of the province was such as to render adequate description impossible. The hospitals were choked so that it was impossible to remove the dead quickly enough to make room for the dying; the streets and lanes of the cities were littered with dead and dying people; the postal and telegraph services were completely disorganised; the train service continued, but at all the principal stations dead and dying people were being removed from the trains; the burning ghāts and burial grounds were literally swamped with corpses, while an even greater number awaited removal; the depleted medical service, itself sorely stricken by the epidemic, was incapable of dealing with more than a minute fraction of the sickness requiring attention; nearly every household was lamenting a death, and terror and confusion reigned everywhere. . . . The great malaria epidemic of 1908 and the worst years of plague fade into insignificance beside this epidemic, which in three months, October–December, killed 962,937 people.”

This mortality is equivalent to 49.8 per 1000 of the population according to the 1911 Census, or 45.8 per 1000 on the population as estimated for the year 1918. The European population escaped lightly. Among commissioned officers and their families, and for Europeans generally, the mortality was trifling, well under 5 per cent. of the cases; at the military asylums of Sanawar and Ghora Galli there were 398 cases and no deaths. For the Indian population of the better class, and among those provided with medical aid, it is estimated at about 6 per cent.; among the poorer classes “anything from 50 per cent. upwards.” Among the jail population in the province there were 4475 cases and 520 deaths from influenza, giving a case-mortality of 11.6 per cent. Rural areas suffered more than the towns, this being due, in Colonel Forster's opinion, to the two circumstances that “for practical purposes the rural areas, even in normal times, are without qualified medical aid,” and “the rural population is unable to benefit from communal effort—itself energised by competent directing authority—to anything like the same extent as the urban population.” The preventive measures considered to be most important are: improvement of housing conditions, as soon as this becomes practicable; the provision of medical aid, at the rate of one qualified practitioner per 100 square miles on an average; antiseptic treatment of the naso-pharynx; attention to personal hygiene; and avoidance of all crowded places. Preventive inoculation is not recommended.

Cholera caused 257 deaths, only 0.01 per 1000 of the population, less than in any year since 1902. Under “fevers,” from which 1,287,027 deaths were registered, giving a death-rate of 66.56 per 1000 (as compared with the quinquennial mean of 19.12), the large increase was due to influenza. At Simla there were 22 cases of enteric fever, 15 being among Europeans in various parts of the station, and apparently unconnected with each other. There were 3032 deaths from small-pox, compared with 1417 in the previous year (0.16 and 0.07 per 1000 respectively). Vaccination was interfered with by the influenza epidemic. Colonel Forster has made a good start in the education of the general public in matters of elementary hygiene. He has had diagrams and lantern slides prepared from photographs taken by himself, and intends developing this work, which is likely to have excellent results.

REFRACTOMETERS.

APPLICATIONS of the refractometer to physiological and clinical analysis have received of late years a great deal of attention in Germany and America. Since refractometers are now among the none too numerous scientific instruments which in this country are made better than in any other it is to be hoped that their applications to such problems will be encouraged. The Abbe and Dipping refractometers are well known to organic chemists, and are generally regarded as indispensable instruments

in chemical research or control laboratories. Numerous papers have been written on the refractometer in physiological and clinical analyses. Robertson's method of estimating the proteins in 0.5 c.cm. of blood serum may be specially mentioned. Abderhalden gives a bibliography of the use of this instrument in the examination of blood, urine, cerebro-spinal fluid, &c., and for the control of the action of ferments and bacteria. Full particulars and reference to many such applications can be obtained from Messrs. Adam Hilger, Ltd., of 75A, Camden-road, London, N.W.1, who are makers of these instruments.

THE SPELMAN APPEAL.

IN our issue of May 15th last we published a moving appeal by Dr. P. J. Delaney in behalf of the widow and children of the late Dr. A. P. Spelman, of Dunmore, co. Galway, who was killed in a motor-car accident at the age of 26, leaving his family unprovided for. The list of subscribers to the Fund up to date is as follows:—

£10 10s.—Dr. McArdle, Merriem-square, Dublin; Dr. Burgess, Victoria Park, Manchester; Dr. Meade, Fitzwilliam-place, Dublin.

£5 5s.—Dr. Meenan; Stephen's Green, Dublin; Sir Wm. de Courcy Wheeler, Fitzwilliam-square, Dublin; Dr. Vincent Tighe, Upper Leeson-street, Dublin; Dr. E. B. Kinsey, Trinity Terrace, Derby; Dr. McLaverty, Merriem-square, Dublin; Dr. Mooney, Fitzwilliam-place, Dublin; Dr. P. J. Delaney, Claremorris, co. Mayo; Dr. T. A. Heneghan, Ballindine, co. Mayo.

£5.—Dr. McMichael, Tullamore, King's County; Dr. Kane, Rossington Lower, Doncaster; Dr. Melville, Church-square, Basingstoke; Dr. Phelan, Callan, co. Kilkenny; Capt. Richardson, R.A.M.C., 29th King's Liverpool Regiment, Calais; Dr. Cassidy, Lisnaskea, co. Fermanagh; Dr. Law, Coleraine, Derry.

£3 3s.—Dr. Mahon, Nile Lodge, Galway; Dr. McGuinness, Harcourt-street, Dublin; Dr. Morris, Devon-place, Galway; Dr. Flannery, Hollymount, co. Mayo; Dr. Rendall, Forest-grove, Nottingham; Dr. P. J. Kenelly, Tralee.

£2.—Dr. T. MacDonagh, Galway; Dr. Kennedy, Merriem-square, Dublin.

£2 10s.—Dr. McKinney, Lower Fitzwilliam-street, Dublin.

£2 2s.—Dr. O'Hea, Leeson-street, Dublin; Dr. Walsh, Westport, co. Mayo; Dr. O'Carroll, Merriem-square, Dublin; Dr. Gray, Kiltormer, Ballinasloe; Dr. Ronayne, Trafford Park, Manchester; Dr. Mangan, Carna, co. Galway; Dr. Dargin, Stephen's Green, Dublin; Dr. McNulty, Killala, co. Mayo; Dr. Martin, Clifton Vale, Clifton, Bristol; Dr. Elliott, Hookstown, co. Tyrone; Dr. Peck, Laton-road, Hastings; Dr. Solomons, Fitzwilliam-square, Dublin; Dr. MacLeod, Port-street, Evesham; Dr. Purcell, Blessington, Dublin; Dr. Brennan, Idione Terrace, Blackrock, Dublin; Dr. Lagan, Omagh, co. Tyrone; Dr. Redmond Keating, Tralee, co. Kerry; Dr. Keogh, Lower Fitzwilliam-street, Dublin; Dr. Kelly, Roscommon; Dr. Gilmour, Stephen's Green, Dublin; Dr. Ryan, M.P., Wexford; Right Hon. M. F. Cox, Merriem-square, Dublin; Dr. Doolin, Fitzwilliam-square, Dublin; Dr. Lockhart Stephens, Emsworth, Hants; Dr. Fitzgerald, Hollymount, co. Mayo; Dr. McDonnell, Vicker's Croft, Galway; Dr. Flannery, Tubbercurry, co. Sligo; Dr. Doyle, Gurteen, Sligo; Dr. Ryan, Clondalkin, Dublin; Dr. Florence Stoney, Poole-road, Bournemouth.

£2.—Dr. Clarke, Loughlin, co. Roscommon; Dr. McNery, Ballymacaburry, Waterford; Dr. G. McGuire, Claremorris, co. Mayo; Dr. Pollard, Cumberland-road, Bristol; Captain C. S. Hamilton, R.A.M.C., Exeter; Dr. Forde, Castlereagh, co. Roscommon; Dr. Wilson, Ashton Lodge, Tunbridge Wells; Dr. Bride Martyn, Holgate Hosp., Lintorp, Middlesbrough; Dr. Cooney, Lusk, co. Dublin; Dr. Macnamara, Corofin, co. Clare; Colonel Macnamara, Corofin, co. Clare.

£1 1s.—Dr. Knott, Castlebar, co. Mayo; Dr. Stokes, Fethard, co. Tipperary; Dr. Wilson, Mercer's Hosp., Dublin; Dr. M. Ryan, Drury-lane, London; Dr. Barnaville, Lower Fitzwilliam-street, Dublin; Dr. Keane, Ennistymon, co. Clare; Dr. Broderick, Cabinteely, Dublin; Dr. Hawshaw, Ballinrobe, co. Mayo; Dr. Cox, Med. Sec., B.M.A., Strand, London; Dr. Pope, The Garth, Hereford; Dr. E. Minceliens, Brook Hosp., Shooter's Hill, London; Dr. Burke, Princes-square, London; Dr. Hawkins, Constantine House, Avonmouth; Dr. Whiteside, Fazeley, Tamworth; Dr. McNeill, Pitlochry, England; Dr. Beirne, Charlestown, co. Mayo; Dr. Corboy, Fort Prospect, Limerick; Dr. Thompson, Tuam, co. Galway; Dr. Barry, Philipstown, King's County; Dr. Staunton, Swinford, co. Mayo; Dr. Mills, Ballinasloe, co. Galway; Dr. Casey, Clifden, co. Galway; Dr. Sandays, Gort, co. Galway; Dr. Brown, St. Catherine's-place, Edinburgh; Dr. Ffennell, Southbourne, Bournemouth; Dr. Ryan, Glenlara, co. Tipperary; Dr. Campbell, County Hosp., Galway; Dr. Murphy, St. Patrick's Hill, Cork; Dr. Ryan, Pembroke Villas, London; Dr. Shepherd, Tulse Hill, London; Dr. O'Gorman, Gowran, co. Kilkenny; Dr. Duncan Scott, Simington, Cambridge; Dr. Dudley, High-street, Stourbridge, Worcester; Dr. Johnstone, Royal Asylum, Morningside, Edinburgh; Dr. Berry, Burnham, Somerset; Dr. Blight, Newport-road, Cardiff; Dr. McMillan, Roseberry-terrace, Glasgow; Dr. King, Dalkey, co. Dublin; Mr. Frank Healy, National Bank, Claremorris; Mr. Edward Fitzgerald, Ballinrobe; Dr. Charlotte Warner, Newcastle, co. Down; Dr. Branford Morgan, Tombland, Norwich; Dr. Rossiter, Ballinasloe, co. Galway; Dr. Waters, Carbury, co. Kildare; Dr. O'Brien, Merriem-square, Dublin.

£1.—Dr. Evelyn Fisher, Glyncorrwg, Port Talbot; Dr. M. McDonagh, Galway; Dr. Orton, Coventry, England; Dr. MacHenry, The Crescent, Galway; Anon.; Dr. Crean, Ballyhaunis, co. Mayo; Dr. McBride, Castlebar, co. Mayo; Dr. Madden, Kiltimagh, co. Mayo; Dr. Scanlon, Chelsea, London; Dr. Dickson, Loughgelly, Fife; Dr. M. Lee, Newport, co. Mayo; Dr. Crowley, Loughrea, co. Galway; A Friend (per P. J. Kenealy, Tralee); Dr. O. Sullivan, Crookstown, co. Cork; Dr. Mark Love, Lansdown, Stroud, England.

10s.—Dr. Hollis, Hove, Brighton; Dr. O'Malley, Gort, co. Galway; Sir James Verrall, Entry Hill, Bath.

7s. 6d.—Anon.

The list is signed by Dr. P. J. Delaney, Claremorris, and Dr. T. A. Heneghan, Ballindine, both in co. Mayo, to whom further subscriptions may be sent.

The Croonian Lectures

ON THE

PSYCHOLOGY OF THE SPECIAL SENSES AND THEIR FUNCTIONAL DISORDERS.

Delivered before the Royal College of Physicians of London, June, 1920,

By ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

LECTURE I.—CUTANEOUS SENSIBILITY AND CUTANEOUS ANÆSTHESIA.

MR. PRESIDENT AND GENTLEMEN,—When I received the honour of being invited to deliver the Croonian lectures it seemed to me right that I should attempt to apply some of the lessons I had learnt during the war to the problems of civil life. I was fortunate in having almost unique opportunities for investigating the neuroses, which occurred so frequently under the exceptionally trying conditions the British Army had to face on every front. In the course of my investigations on their origin and nature I made a number of observations which throw, I believe, some light on the psychology of the special senses and the physiology of the reflexes associated with them. As the most common neurosis affecting the special senses was hysteria, and as my views on the nature of hysteria differ from those held by the majority of neurologists, it will be necessary to explain what I mean by hysteria before I approach the main subject of these lectures.

NATURE AND DEFINITION OF HYSTERIA.

The word hysteria was first used by the Greek physicians to describe what is now known as an hysterical attack, under the impression that it was due to an actual displacement of the uterus into various parts of the body. In course of time numerous other conditions were recognised as being of a similar nature, and the word hysterical was used to describe them all. The etymology of the word coloured all the theories of the nature of hysteria up to the time of Charcot, almost every writer believing that it was associated with pelvic disorders and that it occurred only in women. Charcot, however, showed that it was not uncommon in men, and the earlier idea of its relation in women to pelvic disorders has been gradually discarded. The conception of the disease which I shall use in these lectures has nothing in common with the original one, and it might therefore be considered wise to use some other term than hysteria to describe it; but since this word has been accepted for so long a period by physicians in every country, it would be impossible to introduce any new term which would obtain universal approval. The word hysteria is indeed no more unsuitable than such words as rheumatism and chorea, which have also lost their original significance.

One common factor in all the symptoms, which are by universal consent regarded as hysterical, is their origin as a result of suggestion. When the history of each case is carefully investigated it is almost invariably possible to discover that some event or condition suggested its onset and led to the exact form of the symptoms present. If the view be accepted that hysterical symptoms are caused by suggestion, they must be capable of removal by psychotherapy without assistance from any more material method of treatment. We can thus state that an hysterical symptom is one which has been produced by suggestion and is curable by psychotherapy.

Physical Stigmata.

Gendrin, in an address to the Académie de Médecine in 1846, stated his belief that "hysteria is not only characterised by spasmodic attacks occurring at intervals, but it is a continuous disease, which in the intervals always presents characteristic symptoms," the most important of which "is a state of general or partial insensibility." Gendrin's views were to a great extent forgotten until they were revived by Charcot in 1871. Charcot taught that hysteria manifests itself in two ways—by persistent symptoms or stigmata, of which the patient is unaware, and

temporary symptoms, which are obvious to the patient and lead him to seek medical advice. The former were supposed to be present before the latter appeared and to persist after they had disappeared. Amongst these stigmata the most constant, according to Charcot, were retraction of the field of vision, certain forms of cutaneous anæsthesia, and pharyngeal anæsthesia. His teaching soon became universally adopted, and few books on neurology or general medicine published in the last 50 years fail to mention these stigmata.

One of Charcot's most distinguished assistants, Babinski, was the first to throw doubt upon the importance of the stigmata he described. Babinski believes that they are not permanent symptoms at all, but, like the more obvious and temporary symptoms, are produced by suggestion. Instead of being produced by suggestion on the patient's part, they are the result of suggestion on the part of the physician. The evidence brought forward by Babinski in connexion with anæsthesia and retraction of the field of vision appears to me to be conclusive, and receives further confirmation from the investigations which I shall presently describe. We have obtained similar evidence with regard to pharyngeal anæsthesia, so that the question of physical stigmata may be regarded as settled.

It is so common to regard certain mental qualities as hysterical and to apply the term hysterical to a certain type of individual that it requires considerable courage to reject altogether the doctrine of a specific psychical disorder to which the name hysteria can be given. But on examining the literature it is at once apparent that no sort of unanimity exists as to what are the specific mental attributes of hysteria. For several years I accepted the definition of hysteria as an abnormal mental condition in which the individual is unduly prone to develop symptoms as a result of suggestion. But the experience of the war has taught us that, given a sufficiently powerful suggestion, there are probably no individuals who would not develop hysterical symptoms.

Abnormal suggestibility, like other mental attributes commonly regarded as characteristic of hysteria, is undoubtedly a most important predisposing cause of hysterical symptoms, but it is not an essential factor, and cannot therefore be regarded as an essential part of hysteria. As it may exist in an individual who never shows any hysterical symptoms owing to the absence of adequate exciting causes, abnormal suggestibility cannot be regarded as a disease, such as hysteria would designate, any more than irritability or any other mental attribute is a disease. Unless everybody can be regarded as a victim of hysteria, as everybody is liable under sufficient provocation to develop hysterical symptoms, suggestibility is not the mental basis of hysteria. Whether a given person will develop hysterical symptoms under given conditions depends on the degree of his suggestibility and the strength of the suggestion. It is clear therefore that abnormal suggestibility is simply a predisposing factor, and is no more a part of hysteria than a tuberculous family history is a part of tuberculosis. Many cases of gross hysterical symptoms occurred in soldiers who had no family or personal history of neuroses, and who were perfectly fit until the moment that one of the exceptionally powerful exciting causes, such as occur comparatively rarely apart from the war, suggested some hysterical symptom. After its disappearance as a result of psychotherapy the man was once more perfectly fit, and his subsequent history showed that he remained no more liable than any of his companions to develop new symptoms.

As soon as it is recognised that the mental stigmata which predispose to the development of hysteria are not themselves a part of hysteria, it becomes obvious that many cases of hysteria will be missed if it is only looked for in so-called hysterical persons. When, on the other hand, it is remembered that there is nobody who may not develop hysteria if the provocation is sufficiently great, it must follow that hysteria is infinitely more widespread than has generally been supposed.

We thus arrive at the conclusion that, apart from actual hysterical symptoms, there are no underlying physical or mental symptoms or group of symptoms, which precede and accompany them and persist after their disappearance, to which the term hysteria can be applied. It is clear therefore that while it is easy to define hysterical paralysis and hysterical anæsthesia, as they have certain attributes which distinguish them from all other forms of paralysis and anæsthesia, "hysteria" cannot exist in their absence. The only possible definition of hysteria is "the condition in which hysterical symptoms are present," hysterical symptoms being in turn defined as "symptoms which result from suggestion, and are curable by psychotherapy"; hysteria is thus a condition in which symptoms are present which have resulted from suggestion and are curable by psychotherapy.

D

I.—CUTANEOUS SENSIBILITY AND CUTANEOUS ANÆSTHESIA.

(1) *Hysterical Anæsthesia Following Hetero-Suggestion.*

I have already described how Charcot believed that cutaneous anæsthesia was a stigma of hysteria, which was present before any more obvious hysterical symptoms developed and persisted after their disappearance. It had three characteristic features: Firstly, it was rarely, if ever, recognised spontaneously by the patient, and was only discovered in the course of the physician's examination. "Hemi-anæsthesia," wrote Charcot, "is a symptom which requires to be sought for. There are many patients who are quite surprised when its existence is revealed to them." Secondly, it never caused any inconvenience to the patient, who was able to perform movements with normal accuracy so long as no paralysis was associated with it, and it never led to accidental burns or other injuries. Lastly, it always occurred in certain characteristic areas, such as one-half of the body, the whole of a limb, or the area covered by a glove or stocking. (Figs. 1, 2, and 3.)

Doubt was first thrown on the truth of Charcot's view by Herbert Page, who in his book on "Railway Injuries," published in 1891, asked the question, "May not sometimes the very examination of a hemi-anæsthetic patient largely determine the hemi-anæsthesia?" And he then observed that "the examination of a patient may sometimes produce the suggestion whereby anæsthesia results."

Nine years later Babinski failed to find any disturbance in tactile, painful, thermal, muscular, and stereognosis sense in any of a hundred consecutive cases of hysterical disorders, in which he was careful to avoid the possibility of suggestion. He concluded that the anæsthesia Charcot had described as so characteristic of hysteria was not recognised spontaneously by the patient and did not cause him any inconvenience, simply because it was not present until it had been unconsciously suggested by the observer in the course of his examination.

Babinski went so far as to state that there is no such thing as hysterical anæsthesia apart from that produced by the suggestion of the observer. In a paper on the subject published in 1908, I accepted Babinski's teaching without reservation, but from time to time since then I have seen cases in which hysterical anæsthesia appeared to have developed without any possibility of hetero-suggestion by a second person. These isolated cases remained unexplained until recently, when I gradually came to recognise that certain entirely different classes of hysterical anæsthesia exist, which differ from the only form described by Charcot and the authors of most text-books of medicine and neurology by showing none of the three characteristic features mentioned above. The patient is well aware of the existence of anæsthesia before he is examined; it causes more or less inconvenience and may lead to accidental burns and other injuries, and the areas of anæsthesia differ materially from those hitherto regarded as the only ones occurring in hysteria. The hysterical nature of these varieties of anæsthesia, which I shall presently describe in greater detail, may be extremely difficult to recognise, as the anæsthesia is always a sequel of the anæsthesia caused by some organic condition, and resembles the latter in all its details.

In 1917 I carried out some investigations with Mr. R. Gainsborough on the classical forms of hysterical anæsthesia described by Charcot. Twenty-nine healthy and intelligent individuals, of whom 25 were medical students, who had, however, not yet worked in the wards or read any clinical medicine, were asked to pretend that they had been in a railway accident, and that they were attempting to swindle the company by claiming compensation because of paralysis of the right arm and leg, which they alleged had resulted. They were to act as well as they could the part of men trying to persuade the medical examiner that they were really suffering from paralysis.

We first asked them whether there was anything else of which they complained besides paralysis of the arm and leg. The large majority said they were quite sure there was nothing else, even after being pressed for details. These results correspond with what occurs in patients suffering from hysterical paralysis. If they have not previously been examined they hardly ever volunteer that they have any anæsthesia. The following leading question was then asked: "Can you feel as well on your right side as on your left?" Twenty-two out of 27, including 2 who had spontaneously complained of numbness and 1 of coldness, said they felt less on the right side than the left. Another said he felt tingling on the right side. The remaining 4 said they had noticed nothing. This agrees with an observation made by Yealland, which I have since confirmed on numerous occasions. On asking a great number of

non-medical individuals the following question: "Supposing you had loss of power in your wrist, fingers, and thumb, would you, or would you not, lose feeling?" the answer he obtained was always in the affirmative. When asked what would be the limits of the loss of feeling, a line was drawn round the wrist and less frequently round the forearm,

FIG. 2.—Sleeve anæsthesia in hysterical traumatic brachial monoplegia. (After Charcot.)

elbow, or shoulder. The replies to our leading question in the 27 "malingerers" correspond with the first stage in the production of hysterical anæsthesia, the idea of which first enters the patient's head when he is asked questions on the subject.

Cutaneous sensibility was then roughly tested. Six of the "malingerers" had right hemi-anæsthesia (Fig. 4), 5 had complete right hemi-anæsthesia except the face, 12 had anæsthesia of the whole arm and the whole leg (Fig. 5), 1 had hyperæsthesia of the whole arm and

FIG. 3.—Glove anæsthesia in hysterical traumatic paralysis of hand. (After Charcot.)

FIG. 4.—Hemianæsthesia in "malingering" hemiplegia.

whole leg, and 4 had no anæsthesia. Seven were asked what the area of anæsthesia would be if only the hand and foot were paralysed: all replied that they would have anæsthesia of the distal part of the limb only, and

marked out typical glove and stocking areas at various points up the wrist and forearm and ankle and leg respectively (Fig. 6). I asked several other individuals what area, if any, of anaesthesia they would expect to accompany paralysis of the hand, forearm, and whole arm respectively. In most cases the area corresponded with the extent of the paralysis, glove anaesthesia occurring with paralysis of the hand, anaesthesia up to a line drawn round the elbow in paralysis of the forearm, and anaesthesia of the whole arm up to a line drawn through the axilla and over the shoulder with paralysis of the whole arm.

The results of these investigations correspond with the second stage in the production of hysterical anaesthesia. An investigation of cutaneous sensibility in suggestible individuals is very likely to produce anaesthesia, especially if the way has been prepared by questions on the subject, though this is not an essential preliminary. The area of anaesthesia corresponds with the individual's own ideas, just as in these cases of experimental malingering. Figs. 1 to 6 show areas which are generally regarded as typical areas of hysterical anaesthesia; they are really nothing more than the areas which anybody without knowledge of physiology would expect to become anaesthetic when

FIG. 5.—Anaesthesia of whole arm and whole leg in "malingering" hemiplegia.

FIG. 6.—Glove and sock anaesthesia in "malingering" hemiplegia.

the limbs are paralysed, the same individual variations being seen in these cases of "malingering" as in different cases of hysterical paralysis.

(2) Hysterical Anaesthesia Following Stupor.

A condition of stupor was not uncommon in soldiers who were exposed to some exceptional emotional disturbance when their resisting power had already become lowered by prolonged exposure to terrifying experiences, especially if they were suffering from great physical fatigue, the result of strenuous exertion, want of sleep, and perhaps insufficient food. In this condition the patient's mind appears to be so absorbed with his own innermost thoughts that he gives no attention to the external world. He appears to see, hear, and feel nothing. He does not blink when a stick is waved in front of his face, nor jump when a loud noise is made just behind him. He pays no attention to tickling or to painful stimuli applied to his skin. Sooner or later spontaneous recovery occurred in most cases. After a period of confusion the patient became normal in every way, and his vision, hearing, and sensibility to all forms of cutaneous stimuli returned. In most cases the intermediate period of confusion was very short, but it was sometimes prolonged. If during this period the patient happened to be under a medical officer, whose clinical enthusiasm prompted him to make repeated examina-

tions of his motor and sensory functions, the patient's dawning interest in the outside world was focussed on these functions, some deficiencies in which thus became perpetuated as hysterical symptoms. A very striking example of this was a patient who happened to be the subject of intense study by a number of neurologists in the early days of the war, when the true hysterical nature of so-called "shell-shock" was not fully understood. The sensory deficiencies natural to a condition of profound stupor were consequently perpetuated after the stupor disappeared, and resulted in the most complete and widespread hysterical loss of all forms of sensation, except hearing and seeing, which I have ever observed.

Total amnesia with hysterical paralysis, contractures, analgesia, and mutism due to emotional strain; recovery of memory after 22 months and from paralysis after 28 months.—Pte. M., aged 23, with no personal or family history of neurosis, was slightly wounded in the thigh in May, 1915, after serving from the beginning of the war. He returned to the front in October, 1915. He was quite fit until Feb. 19th, 1916, when he had to be forcibly prevented from going over the parapet to attack some German mortars which were firing at his trench. He then became dazed, and on reaching the aid-post he could not answer questions, but he obeyed simple commands, such as to put out his tongue. He believed he was still in the trenches, which were being heavily shelled; his eyes were fixed on imaginary trench mortar shells coming towards him. His knee-jerks were brisk, there was an extreme degree of pseudo-ankle clonus, but the plantar reflexes were flexor. The bowels and bladder remained under control. Two days later the knees and ankles had become stiff; the legs, hands, and face were anaesthetic and analgesic. When he reached England on March 2nd his expression was apprehensive, and he started at every sound, both when awake and asleep. In his dreams he saw the ghosts of Germans he had bayoneted come to take revenge on him, and he heard them fire at him. He was still unable to speak, but he answered questions by nods and signs, and in writing. He was able to walk with assistance. He was treated by hypnotism and the hallucinations disappeared, but his physical and mental condition rapidly deteriorated.

I saw him for the first time in December, 1916, 11 months after the onset. He could not speak, and all four limbs were now completely paralysed, except that he was able, with a great effort, to make slight movements at his left elbow-joint. An extreme degree of contracture was present: the legs were rigidly extended, with the feet plantar flexed; the arms were extended, and the fingers tightly clenched, though the metacarpo-phalangeal joints were extended. It was almost impossible to produce any passive movements, but the contractures were entirely hysterical, as they relaxed completely under an anaesthetic and during sleep. Total anaesthesia and analgesia of the whole body, including the conjunctiva, cornea, and buccal mucous membrane, were present, except that passive movements at the elbow were painful, and he occasionally suffered from toothache. The anaesthesia disappeared, at any rate to some extent, during sleep. Although deep pressure over the abdomen produced no sensation, the sensibility of the bladder and rectum appeared to be present, as he retained perfect control over them. The sense of taste and the sense of smell were obviously much impaired, and the fields of vision seemed to be greatly contracted, but hearing was abnormally sensitive, and the auditory-motor reflexes were extremely brisk. The conjunctival, corneal, and all skin reflexes were absent; when the contractures relaxed under partial anaesthesia the deep reflexes were found to be normal.

On Dec. 15th, 1916, vigorous suggestion with the aid of an intralaryngeal electrode during light etherisation restored the power of whispering. It was then found that the patient had total loss of memory; he had no idea who or what he was, he did not realise that his anaesthetic legs belonged to him, and he had no knowledge of the meaning of words.

During the following months he learnt to talk a kind of pidgin English, but the meaning of every word had to be taught, and he used each word in his limited vocabulary for a variety of meanings. All liquids were "tea," and when petrol was poured into the tank of a motor-car he was in he called out "Table has tea," table being for some obscure reason the name he applied to all vehicles. "Hand" represented a hand and a glove, and "to hand" was to hit. A word taught by other patients in fun would never be given up, so that all forms of meat, chicken, and fish were called "puss." His only numbers were one and six, which represented anything more than one, except a very large number, which was sixty-six, or a still larger number which was six-sixty-six. The sight of his own face in a mirror always terrified him: he did not realise who it was he saw, and turned his head away, saying, "No like you, chick." On seeing in the mirror the face of the sister who was standing by his side, he was greatly amused and said "See six sisters." All attempts to teach ideas of time, space, and colour failed, and he did not recognise any of his relations, even when his father was brought to him in the middle of the night in the hope that he might know him at the moment of waking. He remembered recent events and called people by names which he invented himself; a bald patient was "no-hair chick," and men who limped badly were "no-leg chick" and "six-leg chick"; all officers in uniform were "Major," and civilians "Mister," or, if friends, "Mister Chick."

In spite of treatment no improvement in the condition of his limbs had occurred by October, 1917, though he was able to sit up in a chair and enjoyed being taken out of doors. He delighted in childish toys, and in a general way his mind was that of a year-old child. He was quite happy, but he was becoming very emaciated; it was difficult to persuade him to eat, as he had completely lost the senses of taste and smell, and he apparently never felt hungry.

On Nov. 22nd, 1917, for no obvious reason, he had a headache and became excited in the evening. His memory began to return during the night and he talked incessantly. The next day he

realised the deficiencies in his speech and wished to have them corrected. When told a word he repeated it correctly and remembered it, and he began to form proper sentences. On Nov. 24th I cured a man suffering from hysterical aphonia with a laryngeal sound in his presence. Though this had failed on many occasions since he learnt to whisper nearly a year before, it now cured him instantaneously to his intense delight. He felt something snap in his head, and immediately afterwards he talked quite normally and the memory of his home and his past life flowed back. His father came the next day and he knew him at once. He soon remembered his experiences in France, but his life in hospital for 21 months was a blank, as it seemed to him that he was in France only a few days ago. He had a vague recollection of very recent events and he knew the men in the ward, but did not remember friends who had gone out only a week before. He remembered "feeling funny with a buzzing head," then "something in his head was suddenly relieved," and the buzzing stopped when his memory returned.

Complete anaesthesia and analgesia were still present, and the cutaneous, conjunctival, and corneal reflexes were absent. With his eyes bandaged the only difference he could recognise between hot and cold water, tea and beer was that the tea was "sweet" and the beer was "bitter." Salt was recognised as a powder, but without taste. Jelly was recognised, as it dissolved so quickly in the mouth, but butter was also taken to be jelly. Bread was indistinguishable from fish, and he could not recognise any difference whether it was spread with butter, mustard, or salt. Marmalade appeared sweet, but was not recognised; he guessed that chutney was apple.

His mental condition was now perfectly normal, but for some time very little improvement occurred in the condition of his limbs. With re-education the left arm slowly improved, but it was not until he was transferred to the Seale Hayne Hospital in April, 1918, that any marked change occurred. At the end of a fortnight his right arm, which had hitherto remained rigid and paralysed, had improved so much that he could write long letters, brush his hair, and feed himself, but all movements were stiff, shaky, and slow. The left arm improved at the same time, but there was still no recovery of voluntary power in the legs. On May 1st a renewed attempt was made to overcome the rigidity of his legs. This was so far successful that slight voluntary power returned in the feet. Steady improvement followed until all movements became possible, the adductor spasm of the thighs being the last to relax. By May 31st he could stand with very little assistance and could perform all ordinary movements with his arms, though some rigidity was still present. On June 2nd, his twenty-fifth birthday, he stood without support, and after being helped for a few minutes he walked without assistance round the quadrangle after having been paraplegic for 28 months. His physical condition now steadily improved, and by June 20th he was able to take charge of the basket-making shop. The sensibility of his skin and mucous membrane slowly returned without special treatment, but was still somewhat deficient in August. The superficial reflexes returned *pari passu*. Thus, the abdominal reflexes were absent so long as anaesthesia was complete. When at length a strong faradic stimulation could just be felt on the left side, a weak reflex appeared on this side. The right reflex only returned at a later date when the right side of the abdomen was no longer completely anaesthetic, but it was still weaker than the left, corresponding with the fact that sensibility was more nearly normal on the left than on the right side. In the same way the corneal and conjunctival reflexes returned with the return of the sensibility of the cornea and conjunctiva.

By September, 1918, recovery was complete. The last trace of contracture of the fingers and of unsteadiness in gait had disappeared. The patient had regained his weight and was in every way as fit as when he first joined the army. Since then he has remained perfectly well.

(3) *Hysterical Anaesthesia Following the Anaesthesia Caused by Injury to Peripheral Nerves.*

The paralysis and anaesthesia following an injury to a peripheral nerve, which is caused by the interruption in the nervous impulses passing between the central nervous system and the periphery, may both be perpetuated as hysterical symptoms when the interruption is no longer present.

A gunshot wound in the immediate neighbourhood of a nerve produces minute changes in its structure which quickly disappear, but, evanescent as these concussion changes are, they are none the less organic, and the paralysis and anaesthesia they produce are primarily of organic origin. The patient may at first make repeated attempts to contract the muscles supplied by the nerve, but, as he invariably fails, he finally discontinues and realises that the muscles are paralysed. If the true nature of the condition is recognised and the patient is encouraged to repeat his attempts every day, he will find in a very short time that his power is returning. If, on the other hand, the condition is misunderstood, and the patient is ordered treatment with electricity and massage, and is given to understand that he may have to continue with this treatment for weeks or months before recovery can take place, the original tendency to perpetuate the incapacity by auto-suggestion is greatly strengthened by the hetero-suggestion involved in the treatment, with the result that by the time the nerve has completely recovered the organic incapacity is replaced by an exactly similar hysterical incapacity. In the same way the primary organic anaesthesia is perpetuated as hysterical anaesthesia with all its characteristics unaltered, particularly if the patient's attention has been drawn to its extent and its exact nature by the thorough investigations of a keen

and interested medical officer in the early stages when the condition was still organic. If the nerve is more seriously damaged, especially if it has been divided and subsequently sutured, the primary organic condition lasts for a longer period, and its characteristics are all the more likely to become vividly stamped on the patient's mind and to become perpetuated as hysterical phenomena when recovery from the actual injury at last occurs.

I am convinced that the voluntary power of paralysed muscles returns before the response to faradism when an injured or divided and sutured nerve is regenerating, an opinion which is shared by most observers. When complete paralysis has been present for many weeks it is natural that a man should cease to make an effort to move the affected part, so that it is extremely likely that he will not become aware of his returning power at the first moment that the regenerating nerve is capable of conveying motor impulses. If left to himself he will probably only make the discovery some weeks later, when a considerable degree of power has returned, and the normal electrical reactions are re-established. If he is receiving regular electrical treatment, the discovery of a response to faradism is likely to prompt the operator to tell him to make an effort to move, which will in all probability be successful owing to the suggestive effect of the ocular demonstration of the movement produced by the electricity. Under more favourable conditions the patient is seen frequently by the physician, who encourages him to make daily efforts to contract the paralysed muscles, with the result that the returning power is recognised at an early stage—frequently before there is any response to faradism. I believe that the exceptionally early recovery of function after nerve suture, which is occasionally observed, is due to the patient having discovered that he can contract the paralysed muscles within the first few days after the nerve has regenerated sufficiently for a few feeble impulses to be conveyed along it.

If from the beginning no attention is paid to the anaesthesia, it disappears spontaneously when the motor symptoms are cured. If, however, it has been carefully investigated, and its extent and nature have become thoroughly recognised by the patient, it is likely to persist as hysterical anaesthesia. It can then be cured almost instantaneously by the suggestive effect of the application of a faradic current, the patient being first told that his sensation will at once return when the electricity is applied. He quickly feels the electricity, and directly afterwards it is demonstrated to him that he can now also feel the lightest touch as well as pain, and can distinguish accurately between hot and cold. This immediate recovery with suggestion proves that the condition must be genuinely hysterical.

The exact area involved when the condition is no longer organic depends largely upon the intelligence of the patient and the interest he takes in the examination of his anaesthesia, and partly on the physiological and anatomical knowledge of the observer, who would be likely to influence the patient by his own ideas on the subject, both whilst the condition was organic and after it became hysterical, unless he was unusually expert in avoiding the liability to suggest what he expected to find. The following case is selected from several we observed in which hysterical anaesthesia showed a distribution exactly similar to that produced by an organic injury to a peripheral nerve.

Hysterical anaesthesia of the median nerve following a wound of the forearm.—Pte. B., aged 36, was wounded in the right forearm on Sept. 5th, 1918. His hand became paralysed and there was anaesthesia in the area of skin supplied by the median nerve. After being treated by massage for three months he was admitted to Seale Hayne Hospital under Captain S. H. Wilkinson on Jan. 20th,

FIG. 7.—Hysterical anaesthesia in median nerve area.

1919. Hysterical contracture of his fingers prevented him from flexing them, and he complained of numbness of the thumb and the first two and a half fingers. (Fig. 7.) He was treated by percussion and re-education, and at the end of two days the motor power of his hand was normal. Sensation was then restored in a few minutes by suggestion with the aid of faradism.

Direct treatment of hysterical anaesthesia following a nerve injury is, however, often unnecessary, even if the patient is well aware of its existence, as it is sufficient to point out to him, as in the following case, that as soon as his power of movement returns the loss of sensation will disappear.

Spontaneous disappearance of hysterical anaesthesia of the ulnar nerve on recovery from associated paralysis.—Pte. B. was wounded in the upper arm on August 29th, 1918. He developed a contracture

of the ring and little fingers, and cutaneous anaesthesia of the area of the skin supplied by the ulnar nerve. He was transferred to Seale Hayne Hospital under Major J. F. Venables on Nov. 10th, 1918, with the ring and little fingers firmly flexed into the palm of the hand and with cutaneous anaesthesia in the area supplied by the ulnar nerve. The paralysis and contracture were treated by persuasion and re-education, and it was explained to him that as soon as he could move his fingers normally the numbness would go. In half an hour he was completely cured, the anaesthesia as well as the contracture having disappeared without any direct treatment by faradism or other form of suggestion.

In the following case the anaesthesia, though hysterical, was so profound that the patient injured himself without being aware of it at the time.

Hysterical anaesthesia of the median nerve, resulting in accidental injuries to the anaesthetic area.—Pte. I., aged 19, was wounded on Oct. 11th, 1918, in the left forearm. His arm and hand were put on a splint and he was transferred to England a week later. On Oct. 20th he tried to use a fork for the first time, and discovered that he could not feel it. He told his medical officer, who found that he had anaesthesia in the area supplied by the median nerve. He was transferred to Seale Hayne Hospital under Captain Wilkinson on Feb. 22nd, 1919, suffering from hysterical paralysis and contracture of the fingers, which were fixed in a semi-flexed position. The margin of the outside of the nail of the middle finger was ulcerated over an area the size of a shilling, and on the extensor aspect of the first finger there was another superficial ulcer. He stated that two days previously he had tried to get the feeling back in his fingers and thumb by holding them in front of the fire. He had been unable to do so, and had not been aware that he had burnt himself until the following morning, when he found large blisters had developed on his fingers.

On the morning of admission his hand was treated by persuasion and re-education, and at the end of half an hour he could open and close it quite strongly in a normal manner. The anaesthesia was treated by suggestion with the aid of faradism, and in a few minutes his cutaneous sensibility was completely restored. He had no further trouble with his hand, the ulcers rapidly healing, and a fortnight later he was discharged.

(4) *Hysterical Anaesthesia Following Cerebral and Spinal Lesions.*

The anaesthesia associated with the paralysis caused by disease or injury of the brain and spinal cord may be perpetuated as an hysterical symptom after partial or complete recovery from the organic lesion, in the same way as the anaesthesia associated with the paralysis caused by injury to peripheral nerves.

I have not, however, made many accurate observations on this subject, except in cases of spinal concussion in which total paraplegia followed a blow on the back. In such cases signs of organic paraplegia were often present at first, and anaesthesia was frequently discovered up to the level of the spinal segment which was principally involved in the injury. Both paralysis and anaesthesia sometimes persisted for months or even years after the organic lesion had so far recovered that it could no longer be responsible for any disturbances in the spinal functions. The paraplegia was almost always amenable to the rapid form of psychotherapy, in which explanation, persuasion, and re-education resulted in more or less complete recovery in the course of a single treatment lasting perhaps an hour. If no attention was paid to the accompanying anaesthesia at the time, it would always be found to have disappeared with the paralysis when a careful examination was made on some subsequent occasion. If, however, the sensory functions were investigated during the treatment they would be likely to persist and require further psychotherapy before they finally disappeared. A patient recovering from paralysis, which was the only symptom in which he was really interested, as it was the sole cause of his incapacity, would subconsciously expect any associated, but to him unimportant symptom, such as anaesthesia, to disappear when the paralysis disappeared, but if his attention was directed to his anaesthesia immediately before or during the treatment he might very well expect that a symptom which so greatly interested his physician would require separate treatment, and he would not recover spontaneously.

(5) *Hysterical Anaesthesia Following the Anaesthesia Caused by Peripheral Anaemia.*

Whenever the hands or feet of healthy individuals get abnormally cold, the anaemia resulting from the contraction of the peripheral vessels is accompanied by a feeling of numbness and diminution in the acuteness of cutaneous sensibility.

Individuals with a feeble circulation are particularly apt to get numb extremities in cold weather, and in Raynaud's disease a similar but much more severe anaemia with a greater deficiency of cutaneous sensibility occurs as a result of vaso-motor spasm, even when the weather is not unusually cold. A man with a poor circulation knows by experience that the best means for preventing attacks of peripheral anaemia is exercise, and that when his hands are becoming abnormally cold and numb, active movements may restore the circulation and cause the numbness to disappear.

It is natural that the immobility caused by paralysis or contracture of a limb, whether the latter is organic or hysterical, should result in deficient circulation, accompanied by numbness and anaesthesia. As the deficient circulation is continuous instead of intermittent, as in the physiological conditions already referred to, the anaesthesia becomes more profound, especially in individuals who have a feeble circulation. The anaesthesia may be so severe that the patient may burn himself without being aware of it, as in the case described below. When the circulation is temporarily improved by immersing the limb in hot water normal cutaneous sensibility returns, and in hysterical cases the improved circulation, which results from the recovery of mobility and disappearance of spasm under psychotherapy, is immediately followed by a return of normal cutaneous sensibility, even if the condition has persisted for months or as long as two or three years.

If, however, much attention has been paid to the anaesthesia which results from the poor circulation in hysterical paralysis and contracture, and its exact extent has been carefully mapped out on several occasions, the symptom takes such a prominent place in the patient's mind, instead of being one of which he is hardly aware, that it is very liable to be perpetuated by auto-suggestion when recovery from the paralysis and contracture takes place. The patient does not associate the anaesthesia with the diminished circulation, but regards it as an independent symptom, which will require separate treatment by re-education or suggestion after the paralysis and contracture have been dealt with. That the anaesthesia is purely hysterical when it persists after recovery from the paralysis is proved by its immediate disappearance with psychotherapy, although this has no effect so long as the paralysis is still present, as the anaesthesia is then a direct result of the peripheral anaemia, and is incapable of amelioration so long as the latter persists.

Hysterical anaesthesia following the anaesthesia caused by peripheral anaemia associated with hysterical paralysis of the hand.—Sergt. H., aged 23, underwent an operation on Jan. 18th, 1918, for the removal of a ganglion from the dorsum of his left hand. He was discharged to duty six weeks later, but two days after returning to work the hand became blue and swollen, and he was re-admitted to hospital. The swelling was lanced, a quantity of pus evacuated, and a splint and fomentations were applied. The wound had healed four weeks later, but the splint was kept on another fortnight. The patient then found that he could not move his fingers and that his whole arm was flaccid and useless. He was sent to the electrical department, and a few days later, while smoking a cigarette and holding it carelessly in his right hand, he brought the burning end close to his left hand. A comrade told him to be careful, but not before he had burnt his finger and caused a blister to appear. He felt no pain from the burn nor from the blister, and this was the first time that it had occurred to him that his hand was anaesthetic. He called the doctor's attention to it. The arm was examined and found to be somewhat wasted, but the anaesthesia was not investigated. A month later the patient was transferred to another hospital, and here the anaesthesia was tested for the first time and was found to extend as far upwards as the neck.

On admission to Seale Hayne Hospital under Captain W. R. Reynell on May 19th, 1918, complete flaccid monoplegia of the left arm was present, and the hand was blue, cold, and oedematous. Complete anaesthesia and analgesia were present over an area similar to that shown in Fig. 5. Treatment by explanation followed by vigorous persuasion and re-education was sufficient to restore the power of the muscles of the shoulder and upper arm in about ten minutes, but there still remained a very slight degree of wrist-drop, and the fingers and thumb could not be moved. After a second treatment lasting about half an hour the power of the fingers was so far restored that the grip on the dynamometer registered 110, and the blueness and swelling had completely disappeared. Two days later the grip was 140, and the patient took part in boxing practice. A fortnight after admission the grip was 180, which is above normal for the left hand, the grip with the right hand being 240. The anaesthesia, which had not altered in degree or extent, was now treated by direct suggestion with the aid of faradism: normal sensibility of the whole arm was restored in a few minutes.

It is clear that in this case the primary anaesthesia which led to the accidental burn was not hysterical. It was caused by the peripheral anaemia, with which the disuse resulting from the hysterical paralysis was associated. When the extent of the anaesthesia was investigated the examination resulted in its spread by hetero-suggestion, a large hysterical element being now present, as the peripheral anaemia could only account for anaesthesia of the hand and possibly of the forearm. The restoration of the circulation which followed the cure of the paralysis must have caused the anaesthesia due to the peripheral anaemia to disappear, but as most of the anaesthesia was already hysterical, this part also became perpetuated by auto-suggestion when the original cause was no longer operative. Consequently the whole of the anaesthesia was ultimately hysterical, and, being hysterical, was capable of being cured by psychotherapy.

In the rare cases in which the anaesthesia associated with hysterical paralysis and contracture appears to develop spontaneously in the absence of any medical examination, it is probably in the first instance due, as in the case just described, to the associated peripheral anaemia. It is thus not primarily hysterical, being only hysterical if it persists after recovery from the paralysis and contracture.

Diagnostic Significance OF NERVE SYMPTOMS IN ACUTE INFECTIONS.

Being the Harveian Society's Oration.

BY SIR THOMAS HORDER, M.D. LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS TO ST. BARTHOLOMEW'S
HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—I have chosen a subject for my address this evening which is topical because the first considerable outbreak of cerebro-spinal fever occurring in Great Britain in modern times has been followed more recently still by two large waves of epidemic influenza, overlapping more or less with an epidemic of encephalitis. These events have provided ample material both for investigation and forethought. And now a fair number of sporadic cases of all three of these diseases gives us opportunities for application of the lessons we may have learned and for revision of these lessons in so far as they have been too hasty by vice of the limited time at our disposal during the stressful period of the war. A difficult subject because I am anxious to give you, not merely a digest of other people's opinions, so much as a tentative presentation of my own experiences.

I. INTRODUCTORY.

The problem so frequently facing us, of a patient taken suddenly or acutely ill with a disease whose symptom-complex contains elements of a nervous kind, whether subjective or objective, and demanding careful investigation, is so familiar that I will not stay to dilate upon its importance. This problem forms the practical basis of my remarks this evening. It is not a problem essentially for the bacteriologist, though his help may be, and oftentimes is, invaluable. It is not a problem essentially for the neurologist, though his researches and his teaching are of great assistance in the diagnostic argument which arises from a study of the case. It is essentially a problem for the practitioner. Not only the patient and the patient's friends, but the bacteriologist and the neurologist also, wait upon him in such a case. In spirit and in outlook, and in the first instance, he must be the bacteriologist and the neurologist, though not necessarily in laboratory experience nor in technical knowledge. It is the practitioner who makes the first approach and who has the onus of attempting the first diagnosis. Few cases, if any, try his resources more thoroughly than patients of this class, and yet few cases reward him more for careful and methodical study. I can only hope to indicate this evening the bare lines upon which, as it seems to me, his thoughts may usefully travel when faced with the clinical material of actual practice.

I shall deal with the subject from two points of view: (1) the general or synthetical aspect; and (2) the particular or analytical aspect. Under the first heading I shall consider briefly what are the mechanisms, physiological and histological, by which nerve symptoms in acute infections are produced; under the second heading I shall consider these symptoms themselves and touch upon their diagnostic significance.

II. THE MECHANISM OF PRODUCTION OF NERVE SYMPTOMS IN ACUTE INFECTIONS.

Disease may be defined as the sum of the phenomena resulting from the interaction between the organism and various pathogenetic influences. The "acute infections" are diseases resulting from the interaction between the organism and pathogenetic microbes whose virulence is sufficient to cause rapid disturbance of normal functions in tissues which offer some degree of resistance to the attack. Prominent amongst these disturbed functions in many acute infections are those directly referable to the nervous system. The resultant of these nerve disturbances are what we term nerve symptoms and nerve signs. The mechanism by which disturbance of nerve functions is produced is not the

same in all cases, and in order to get clear conceptions of the pathogenesis of nerve symptoms it is necessary to determine and to distinguish these mechanisms carefully, and to consider which one is present, or whether more than one, in each individual case presented to us.

When a pathogenetic micro-organism assists in causing an acute illness the complete sequence of possible events in respect of its activity includes a focus of invasion, a focus of primary infection, a state of general intoxication, a state of general infection, and a focus of secondary infection. Foci of secondary infection may further intensify the condition of general intoxication and of general infection. In a few diseases all of these processes may occur in fairly orderly and recognisable sequence. They may all of them be seen, for example, in some cases of streptococcus infection. The streptococcus invades the tonsil, a focus of infection arises here (acute tonsillitis), toxæmia results, septicæmia results, a secondary focus of infection takes place in the heart (acute endocarditis) and, finally, the streptococcus reinfects the blood stream from this secondary focus, intensifying the general intoxication. In those acute infections which we term "acute specific diseases" it is common to find a selected series of these possible processes brought into play, and the particular series is apt to be repeated again and again by particular microbes, leading to established disease pictures which are recognisable as such. In other words, diseases caused by certain infecting agents for the most part "breed true," and yield results which justify the use of the term "specific." But not always. There are imperfect instances in disease as there are in any other type of objects. For the most part, again, the "course" of acute specific infections is closely repeated in the majority of instances of the infection, so that the cases compare more or less closely at given stages of the disease process. But, again, not always. There are "immature" and there are "precocious" specimens; there are "gigantism" and "dwarfism"; there is even "progeria" or premature senility. But for simplicity we will confine ourselves to disease-types, and we will omit anomalies.

With these ideas before us, let us glance at a few diseases which exhibit marked nerve symptoms. In *diphtheria* the usual series of events includes a focus of invasion in the fauces, a primary infection at the site of invasion, and a state of general intoxication. In *pneumonia* the series includes an (obscure) invasion focus somewhere in the respiratory tract, a general infection with little or no focal infection, a rapid secondary infection in the lung tissue, and resulting general intoxication. In *cerebro-spinal fever* there is an invasion focus in the naso-pharynx but little or no infection here; invasion of the blood stream but rarely an infection of it; a primary infection in the pia-arachnoid membrane; and a state of general intoxication resulting from this systematised infection. (If it be true, as some authorities consider, that the passage of the microbe usually takes place directly through the lymphatics between the naso-pharynx and the base of the brain rather than through the blood stream, this does but extend the site of invasion; it does not introduce a different conception of the main series of events.) In *poliomyelitis* we postulate an invasion focus in the upper respiratory tract, an invasion of the blood stream, or, again, of the channels between this area and the central nerve-axis, a primary infection of the substance of the brain and cord, and a general intoxication from these tissues.

If these conceptions are justified, as I think they are with our present knowledge, it follows that nerve symptoms arising as part of the interaction already referred to are directly referable to one or more of three different processes by which the nervous system becomes implicated. These three mechanisms by which nerve symptoms are produced are—

1. *By toxæmia*.—Nerve tissues are affected by circulating toxins derived either from a focus of primary or of secondary infection or from a general blood infection. In this mechanism there is no actual involvement of the meninges or of the nerve tissues themselves.

2. *By infection of the meninges.*—As the result of primary or secondary infection inflammatory changes occur in these times and lead to one or more of three morbid pathological processes, either of which may produce nerve symptoms: (a) mere toxæmia resulting from the interaction in the inflamed membrane; (b) irritation and strangling of nerve-roots by the inflammatory products in the pia arachnoid; (c) the accumulation of cerebro-spinal fluid in the cerebral ventricles and in the cisternæ of the spinal cord whereby hydrocephalus and hydromyelia may result.

3. *By infection of the nerve tissues themselves.*—Inflammation takes place in the brain and cord, leading again to three different morbid changes, each capable of contributing its own quota of nerve symptoms: (a) changes occurring directly in the blood-vessels, such as thromboses and hæmorrhages; (b) inflammation and degeneration of the grey matter, and especially of the nuclei, resulting from the infiltrating vascular lesion; (c) secondary changes in the conducting nerve paths.

In the first of these three mechanisms the nerve symptoms manifested by the patient are chiefly "functional" in origin; in the second and in the third of these mechanisms the symptoms are chiefly "organic" in origin. The great significance of these mechanisms lies in this distinction.

Now the virus of each of the acute specific infections tends to set in action all three of these mechanisms, but the degree of this tendency varies with the particular virus. This is a fundamental conception taught by recent research in clinical medicine, in clinical pathology, in bacteriology, and in morbid anatomy. It is only by the combined study of all these methods of observation that we can learn to appreciate the total results of infection. The selective affinities of "specific" micro-organisms are not absolute qualities of these agents, but only relative tendencies. And they must be regarded as such during our deliberations as to what particular interaction is taking place in the patient and as to what particular microbe is giving rise to the disease.

A very pertinent illustration of the truth of the statement that microbic agents tend eventually to set going all three, and not merely one, of the three mechanisms by which nerve symptoms are produced, is afforded by fuller study of the cerebro-spinal fluid in disease, rendered possible by the more frequent performance of lumbar puncture in acute infections. It is found that changes in this fluid are much more common in the course of acute infections than was formerly supposed to be the case. Intermediate between mere toxæmia and actual meningitis we now recognise a state of things to which provisionally we give the term *meningism* or *meningismus*, a condition in which the correlative of intense nerve symptoms is found to be an absolute increase in the amount of the fluid, its existence under increased pressure, a slight increase in its protein content, and a slight increase in its cell content. These symptoms include headache, vomiting, delirium, convulsions, rigidities, and even coma. The condition is not very uncommon in pneumococcus infections in children, in measles, in acute streptococcus infections, and in some others. The symptoms are oftentimes considerably relieved, it may be wholly cured, by the drainage of the fluid incident to the puncture.

Another pertinent illustration of this same truth is yielded by recent experiences of poliomyelitis. Not a few cases of this disease give clinical evidence of involvement of the meninges as well as of the vessels of the underlying nerve substance. Rigidities may occur, and the clinical picture may resemble cerebro-spinal fever very closely indeed. So much so that these cases have been grouped under the term "the meningitic type" of poliomyelitis. In such cases examination of the cerebro-spinal fluid reveals changes that are intermediate between those found in meningism and those found in cerebro-spinal fever. In such cases there is post-mortem evidence for regarding the lesion as a meningo-encephalitis, and not as a mere encephalitis only. In the third place I may bring to your remembrance the old-established observation that the disease we term for convenience "tuberculous meningitis" has

as its pathologico-anatomical basis in most instances considerable inflammation of the brain substance in addition to the characteristic involvement of the meninges, that it is, indeed, a meningo-encephalitis, a fact which explains the depth to which the brain functions suffer throughout the whole course of this fatal disease in the majority of the cases.

Making due allowance, as we certainly must, for this tendency of every microbic virus to set up nerve disturbances by all three of the processes described, we are yet able in a large number of instances of infection, and by a close study of the symptoms themselves, to predict the probable nature of the microbe concerned. And, inversely, given the identification of the microbe concerned, we are often able to predict the probable mechanism by which nerve symptoms will arise.

The mechanism of toxæmia is the one operative in diphtheria and tetanus in the great majority of cases. It is also that by which nerve symptoms arise in most cases of pneumonia, typhoid fever, scarlet fever, and rheumatic fever. Secondary infection of the meninges occurs not infrequently in pneumococcus infection and is relatively more common when the primary infection occurs in the middle ear. In measles the nerve symptoms are usually toxæmic, but the specific virus, though it causes meningism not infrequently, rarely causes a true meningitis. That it occasionally sets up an encephalitis or a myelitis, however, has been long recognised. In mumps an actual inflammation of the central nerve structures sometimes occurs, and recent experimental work suggests strongly that the virus in this disease has group affinities with the causative virus of poliomyelitis (M. H. Gordon). It is possible that the virus of infantile cholera has similar affinities.

Reference has been made already to the tendency in generalised tuberculosis for the mechanism of encephalitic as well as meningitic involvement to be added to that of a toxæmia. In cerebro-spinal fever the meningococcus attacks the pia arachnoid in primary fashion, and this is by far the chief mechanism of production of the long series of symptoms presented in the disease. In some of the more severe and prolonged cases, however, there is inflammation of the underlying nerve tissue, both cerebral and spinal, witness the not uncommon ependymal lesions seen post mortem, and the histological changes demonstrable in the cortex. In poliomyelitis and in encephalitis, be the virus identical or only possessed of group affinity, the primary infection is the central nervous system itself, through intimate vascular infiltration. The mechanism of production of the symptoms in these diseases involving structural changes in the master tissue, it is not surprising that the symptoms are profound and of extremely serious import.

The nerve symptoms present in influenza, though protean in nature, are probably due in the main to a toxæmia, which may be of any degree from mild to intense; meningism is not uncommon; meningitis is rarely present in my experience, since I do not regard those sporadic cases of meningitis in which Pfeiffer's bacillus is isolated from the cerebro-spinal fluid as having any necessary association with influenza; encephalitis undoubtedly occurs in some of the fulminating cases during an influenza epidemic.

III. THE SIGNIFICANCE OF PARTICULAR NERVE SYMPTOMS IN ACUTE INFECTIONS.

Passing now to particular nerve symptoms, I propose to review briefly those commonly met with during the examination of patients suffering from acute infections and to offer certain considerations bearing upon their diagnostic significance.

(i.) *Facies, posture, and temperamental state.*—It is scarcely possible to note these points too carefully or to analyse them too closely. It is here, perhaps, more than anywhere, that the eye of the experienced practitioner is of invaluable service. Too often this series of observations is wholly overlooked, or only considered when some rather glaring feature strikes the doctor's attention, whereas it should be made a matter of routine practice, just as are the pulse, the tongue, and the temperature. In some cases the picture is so

clearly outlined that its significance cannot escape notice. The picture of excruciating pain shown in all its intensity by features which are contorted by the spasm of tetanus reveals quite clearly the nature of this infection. The child curled up beneath the bedclothes, peevishly shaking off the nurse who comes to tend it, or suddenly crying out in the stillness, or picking its lips and teeth with monotonous persistence: the question of tuberculous meningitis comes at once to the mind. The apathetic listless facies of the typhoid patient, lying low in bed, with tremulous hands, muttering, but with no visible signs of distress, is almost as decisive. The young man lying on his side, a bluish flush upon his face, his head thrown slightly back and limbs drawn up, staring for hours before him, resenting interference—such a picture takes us a long way towards a diagnosis of cerebro-spinal fever. And, of late years, the “mask-like immobile facies, with half-open eyes, the patient not so much in real sleep as sleep is indicated to the observer by the expression of the patient,” add possibly a ptosis or a squint, and we are familiar with the picture as highly suggestive of encephalitis.

These are, however, as I have said, easily recognisable clinical pictures, because they are drawn with definiteness and with precision. We must train ourselves to the dimmer outlines, to the impressionist substitution for the completed work of art. But these lesser degrees of facial, postural, and temperamental change baffle description; they must be seen to be identified.

(ii.) *Headache*.—This is the commonest of all the individual nerve symptoms with which we are here concerned; and it is probably the least specific in diagnostic value. So constant a symptom is it in nearly all acute infections that to many it may seem almost valueless for differential purposes. And yet a critical analysis of its features is called for in every case, for it is only by giving the symptom this degree of attention that we obtain a hint of the mode of its production and the nature of the infecting agent. It is necessary to consider the headache in its intensity, its distribution, its persistence, its synchronism with other nerve symptoms, especially with delirium, its course, and the effect upon it of palliative remedies. In the matter of intensity there is little doubt that the headache of meningitis may be the most severe with which we have to deal. Approaching it most nearly is the headache of high grades of toxæmia, especially of typhus, typhoid, and influenza. In encephalitis the headache is rarely so severe as in meningitis. Steady persistence of the headache at the same level of intensity is also suggestive of meningitis; so, too, is the continuance of the headache as the course of the disease progresses. In influenza the headache rarely maintains the level of its early intensity past the third or fourth day; in typhoid it usually disappears completely or moderates very considerably with the onset of the “typhoid state.” In most acute toxæmic states it may be said generally that the intensity of the pain is greater during the onset and early stage of the disease than later. As to distribution, in meningitis there is sometimes a marked concentration of the headache in the occipital region, but when this is so the rest of the head does not usually escape. In influenza the post-orbital and frontal regions are frequently complained of bitterly, other regions often suffering little or not at all. In typhoid the headache is sometimes an intense hemicrania.

Synchronism of headache with delirium has been a valuable diagnostic observation ever since Jenner pointed out the fact that such synchronism almost invariably indicates organic brain disease. Children often show this synchronism by uttering a painful cry, and adults by obvious delirium concerning their headache. In toxæmias, on the other hand—in typhoid and influenza notably—the headache departs with the onset of delirium. It is a common experience to see the typhoid patient racked by headache during the day and muttering quietly and more or less peacefully during the night.

Remedies, whether by local applications or by drugs given internally—unless opiates be administered to the point of physiological doses—usually fail to relieve the headache of meningitis, but they very often ameliorate the pain in toxæmias.

(iii.) *Neuralgias* are more common, in my experience, at the onset and during the first two or three days of some acute infections than is to be inferred from textbook literature. I have been struck by the frequency of their occurrence in encephalitis and poliomyelitis particularly. The nerves affected have most often been one or other branch of the trigeminal or the great occipital. The pain may be exceedingly severe, so as wholly to dominate the clinical picture. These focal pains may precede the headache by some hours. Similar intense neuralgias occur in cerebro-spinal fever also during the early stage. But since influenza and typhoid share this tendency to intense neuralgic pains, though in less degree, care must be exercised not to deduce from them the presence of an organic disease of the nervous system. The point of great practical importance is to remember that their presence may indicate the early stage of a general infection of considerable severity, and therefore help the observer to further examination from this point of view.

(iv.) *Vomiting*, if it occurs at the very commencement of an acute infection, has little or no special significance; it is common to the great majority of fevers—though more common in some than in others—and indicates, with a rigor or a convulsion, with the initial headache and with the malaise, the general invasion of the body by the virus. Vomiting that is repeated after the first day, however, or vomiting which appears after the second day or so, not having occurred at the period of general invasion, has definite differential value, raising the question of organic brain disease, especially meningitis. If the vomiting recurs day after day, the diagnostic value of the symptom is enhanced. There two acute infections in which vomiting of this character has not such special significance. One of these is diphtheria, in which the mechanism of its production has been thought to be a vagus neuritis; the other is severe influenza. In both of these conditions, but especially in the former, the symptom is a bad prognostic.

(v.) *Delirium*.—The features of a delirium should be investigated as critically as those of a headache. Before judging of the significance of delirium in any patient it is well to inquire carefully into the past history and also into the family history. As some persons tend easily to headache, and others are almost immune, so is it with delirium. Delirium may replace headache altogether in patients whose family history includes a psychopathic strain. I have seen such a person become suddenly delirious with the onset of typhoid fever of quite ordinary severity, and entirely miss the least suggestion of headache. Little children, of course, do not suffer from delirium in the true sense of this word, because their minds are not sufficiently developed to make delirium possible. The significance of synchronism and alternation respectively, of delirium and headache, has been referred to already. The period in the disease at which the delirium develops is an important differential point. In typhoid delirium rarely occurs before the tenth day, whereas in meningitis, even in cases of moderate intensity, it may be present from the first. So also in encephalitis. There is an important point of distinction between typhoid and meningitis on the one hand, and pneumonia and influenza on the other; that in the former two diseases there is little necessary relation to be observed between the delirium and the severity of the disease, and in the latter two diseases this relation is usually well marked. As to the character of the delirium, it is generally of a quiet type in typhoid, and not associated with restlessness; in pneumonia and in meningitis, however, this asthenic feature is conspicuously absent. This difference is probably related to the fact that, whereas in typhoid headache and acute discomfort disappear when delirium supervenes, in meningitis the intense headache is still

persisting, and in pneumonia the respiratory distress and the dilating heart are contributing to make the delirium loud and active. A sthenic delirium in typhoid generally means either that the patient is a psychopath, or that he has a secondary meningitis, or, as has been once or twice recorded, he has lost blood profusely by intestinal hæmorrhage, leading to a maniacal state from cerebral ischæmia.

(vi.) *Coma and allied states.*—Coma has always been regarded as a worse prognostic than delirium, and this opinion is borne out by the knowledge that in an acute infection coma is much more suggestive of involvement of the meninges or of the brain tissue than is delirium. Deep coma, from which the patient cannot be roused, is very likely indeed to indicate a meningitis. An appearance of sleep—*lethargy*—from which it is possible to rouse the patient for the purpose of examination and questions, the while he tends to fall back again into a state of apparent somnolence, we have learned to associate with inflammation of the brain substance; it is the feature which has led to the name *encephalitis lethargica* for those cases occurring recently in epidemic form in this country, in America, in France, and elsewhere. Whether these cases have been due to the virus of poliomyelitis or to some closely allied virus is still a matter of investigation. A state of *stupor*, which is neither coma nor lethargy, is very common in severe cases of cerebro-spinal fever and when associated with mental irritability and resistance to examination constitutes a very recognisable picture in this disease. A special kind of stupor is the condition termed *comatovigil*; it is almost confined to cases of severe toxæmia, and especially typhus and typhoid; it indicates a very grave degree of the acute asthenia of infection.

(vii.) *Muscular hypotonus and hypertonus.*—The state of flaccidity or of rigidity which is often so conspicuous a part of the general facies requires special attention. In most toxæmic states the tendency of the musculature is towards diminished tone—typhoid, influenza, pneumonia, pyogenic infections generally. The onset of meningism, however, as a complication in either of these infections abolishes this hypotonus. In encephalitis hypotonus is a very marked feature after the first two or three days, excepting the type of the disease termed the meningitic type. In cerebro-spinal fever the condition is the antithesis of this, hypertonus being present, and leading to those rigidities which have come to be regarded as cardinal points in the diagnosis: stiffness of the neck, with a tendency to retraction, tautness of the hamstrings giving rise to Kernig's sign, and other manifestations of the same general state.

(viii.) *Focal paralyses and pareses.*—These are perhaps the most conclusive of all nerve symptoms pointing to direct involvement of the nervous system in acute infections. When present in the early stage of such a disease they suggest strongly that the infection has already set up changes in the cerebral or spinal centres; in other words, that an encephalitis or a myelitis is present. We therefore make a special examination of the eyes for internal or for external ophthalmoplegia, and for ptosis, partial or complete. A complaint of diplopia, whether made by the patient to the doctor, or recorded by an intelligent relative, is never to be passed over lightly, for even if no strabismus is found on examination the occurrence of transient double vision is highly significant. An entirely fresh examination must be made at each visit to a patient suspected of an encephalitis, because these pareses of the eye muscles come and go, but do not thereby lose in significance. It is estimated that some form of ocular palsy, if we include ptosis in this term, occurs in over 70 per cent. of all cases of encephalitis. No doubt the greater frequency of squint in meningitis when it is due to the tubercle bacillus than when it is due to the meningococcus, is explained by the fact that the mechanism of an actual encephalitis is more often superadded in the former than in the latter infection. Critical examination of the face, and especially of the mid-facial movements, is equally important, taking care to secure absolute symmetry of the patient's head

and equal illumination on both sides during the investigation. The limbs are subjected to similar observation for evidence of weakness, both as a whole and in regard to muscle groups. A doubtful diagnosis of encephalo-myelitis may be definitely established now and again by finding polar effects emerge as the course of the disease proceeds—a weak hamstring or quadriceps group, a foot-drop or paresis of the abductor indicis or muscles of the thenar eminence in one hand.

(ix.) *Changes in the reflexes and tendon-jerks.*—These call for great discrimination, and not a little forbearance, in their interpretation. The reasons for this are two: with the exception of the knee-jerk, and perhaps also of the ankle-jerk, there is no constancy in regard to their presence in health in certain persons; on this account the criteria by which we judge the significance of the absence of the "reflexes" in disease are by no means strict; but, secondly, almost any severe toxic process may cause the reflexes to disappear, and this applies especially to the tendon-jerks. In typhoid fever, for example, and in severe pneumococcus infection, myotatic irritability may be much reduced and the knee-jerk may be unobtainable. A third factor comes into play and adds to the difficulty, and that is our inability at times, when the patient is very acutely ill, to apply the reinforcement method customary in cases of less severe illness when the knee-jerk is not obtained by the ordinary method. Two signs, however, are extremely helpful when they are present, and in both instances they are strongly suggestive of organic disease of the nerve centres or conducting paths of the cord: (1) asymmetry in the reflexes on the two sides, and (2) variations in the reflexes from day to day. I have been struck of late by the variations—vagaries, I might almost say—of the reflexes in some cases of poliomyelitis and poli-encephalitis during the stage of the disease following upon the general febrile disturbance. To-day the knee-jerks may be present, to-morrow absent, the third day exaggerated—perhaps with true ankle-clonus superadded—two days later the clonus may have gone and the knee-jerks may be difficult to obtain. The same remarks apply to the plantar response: on one day it may be flexor, upon another extensor, and then again it may revert to its normal type. And with these vagaries in the quantity and quality of the reflexes lack of symmetry may coexist, showing variations no less marked and no less rapid. I believe that these observations, if present, are highly diagnostic of encephalo-myelitis.

In meningitis, for the most part, a state of hypertonus exists, owing no doubt to the irritation of the nerve roots by the inflamed pia-arachnoid and its extensions forming the sheath of these roots. It is not, therefore, surprising that in the majority of cases of cerebro-spinal fever the knee-jerks persist or become exaggerated. Owing to the fact, already observed, that in most acute toxæmic cases likely to be mistaken for cerebro-spinal fever the knee-jerk is temporarily abolished, I usually consider that their retention, still more their increase, in any doubtful case, favours the diagnosis of cerebro-spinal fever.

(x.) *Intolerance of light and sound.*—I have learned to attach very little importance to these symptoms in acute illnesses for any diagnostic value they possess. I am aware that *photophobia* is regarded as an important indication of possible meningitis by many, but I believe it to be much more an indication of the severity of a headache and of the general nerve disturbance than a feature of any distinctive significance. I was once asked to go to the country urgently to see a woman suffering from high fever, intense headache, and photophobia, and was commissioned to bring the materials for lumbar puncture because the diagnosis of meningitis was almost certain. When I arrived the patient was in a darkened room, an ice-bag had been applied to her head, the nurse was walking noiselessly in the room, and my request that the patient should open her eyes so that I might see them was met by a statement that this was not possible on account of the extreme photophobia. I passed on to an examination of the legs, and I found

the cause of the phrenitis: a very acute streptococcal infection on the dorsum of a foot, with livid red streaks of lymphangitis spreading from it. The woman had been bitten by a gnat at this spot whilst playing tennis two days before. The rapid and satisfactory response to treatment made it certain that no meningeal complication had taken place.

The more severe the headache and the more ill the patient—short, of course, of coma—the more intolerant are the senses of sight and sound. Beyond this I do not think these symptoms take us.

(xi.) *Sphincter troubles* occasionally offer a differential element of no slight import. Retention of urine may be the first symptom of acute poliomyelitis. I remember the case of a young cadet in whom it existed for a whole day and night before he felt ill enough to report himself sick: two days later he was laid up with fever and severe pains in the head, back, and limbs, and on the fourth day he had focal paralyses in both lower extremities. The occurrence of retention of urine as part of the invasion-symptoms of an acute illness should always suggest this disease. It is rare, I think, in cerebro-spinal fever at the onset, unless, of course, the case is a fulminating one and the patient is already comatose when the examination is being made. In the toxæmic states of influenza and typhoid it must be very rare.

(xii.) *Deafness* is a not infrequent symptom quite early in typhoid fever, or developing during the course of the disease. The mechanism of its production is not clearly defined, but it is probably a toxæmic effect upon the auditory centre. In cerebro-spinal fever, deafness, if it appears, is usually late, and is very apt to be a permanent sequel. It is almost certainly due to the strangling of the auditory nerve roots by plastic exudate and thickened meninges. In typhoid fever it nearly always disappears, with defervescence of the fever. In other infections, if deafness be present, it is due to infection of the middle ear, and the course of the symptom depends upon the course taken by the otitis media.

(xiii.) To these focal palsies we may add *aphasia*. Care needs to be exercised in its interpretation when present, which is but seldom, in an acute infective process. It is an old observation that it may occur in typhoid. I know of no other toxæmic state in which it occurs—the aphasia and headache of a severe mægrim occasionally confuse the observer—so that its presence in a doubtful case should raise the question of tuberculous meningitis, for in adults this disease may be ushered in by aphasia. Children, it will be remembered, do not show this symptom.

I think it sufficiently obvious that the limits of clinical observation in this subject, as in others, have not been reached. It is probable that they never will be reached. The careful analysis of the symptom-complex is called for more and more on the part of all of us, and the process carries with it results of great practical value.

THE INTRAVENOUS USE OF ACETYL-AMINOPHENYL SALT OF ANTIMONY (STIBENYL) IN THE TREATMENT OF HUMAN TRYPA- NOSOMIASIS AND KALA-AZAR.

BY PHILIP MANSON-BAHR, D.S.O., M.D., M.R.C.P.,
ASSISTANT PHYSICIAN, TROPICAL DISEASES HOSPITAL, ENDSLEIGH-
GARDENS, AND ALBERT DOCK HOSPITAL, E.; LECTURER,
LONDON SCHOOL OF TROPICAL MEDICINE.

In this paper I propose to recount recent experiences with the injection of an organic compound of antimony which may in the future have an influence upon the treatment of these two protozoal diseases.

History of the Therapeutic Use of Antimony Salts.

Antimony salts were first proposed for use in trypanosomiasis by Nicolle and Mesnil¹ in 1906; the following year Plimmer and Thomson² noted the sterilising effect of injection of potassium and sodium antimonyl tartrates in rats experimentally infected with trypanosomes.

The intravenous injection of tartar emetic in trypanosomiasis was first successfully undertaken by Broden and Rodhain³ on the Congo from 1906 to 1908.

In 1910 Kerandel,⁴ having himself unfortunately contracted the disease, after trying atoxyl in vain, reported the successful treatment of his own case by intravenous antimony tartrate. Since that date cases at the London School of Tropical Medicine have been treated with a considerable degree of success by a combination of atoxyl given by the intramuscular and tartar emetic by the intravenous route.

The treatment of leishmaniasis by antimony salts was first attempted by Vianna and Machado⁵ in 1913 in two cases of dermal leishmaniasis in Brazil. In 1914 and 1915 we find antimony tartrate being used in the visceral form of leishmaniasis, or kala-azar by di Cristina and Caronia⁶ in Italy.

More recently tartar emetic has been used with success in India by Rogers,⁷ Mackie,⁸ Muir,⁹ and by Low¹⁰ in this country. Rogers¹¹ has noted that the maximum dose of this drug should be reached very gradually and should be approximately 2 gr. for an adult in a 1 per cent. solution given every third day over some two or three months.

Latterly Rogers¹² has given up using tartar emetic in favour of sodium antimonyl tartrate, finding that the latter salt can be better tolerated and given at more frequent intervals. The solutions must be made up freshly before each injection, as if kept in stock they are apt to decompose and elaborate toxic products. A considerable stimulus to the use of intravenous antimony was given by the work of Christopherson¹³ upon the cure of bilharziasis by tartar emetic, both with regard to the impunity with which the drug may be pushed in that disease and the large amounts which may be given in a comparatively short period (25 to 30 gr.) within three weeks.

Objections which have Arisen in the Use of Tartar Emetic in these Protozoal Diseases.

In the treatment of kala-azar and trypanosomiasis certain objections have been founded on the intolerance which some persons exhibit towards this drug, as well as the alarming reactions which have sometimes been found to follow the use of antimony tartrate in these protozoal diseases. Rogers has recorded three deaths following its use and Low¹⁴ has noted the large amounts—64½ gr. over a period of four months—necessary to cause destruction of the Leishman-Donovan bodies. Daniels and Newham¹⁵ record the successful treatment of Rhodesian trypanosomiasis, in which very large doses of tartar emetic—over 500 gr.—were injected over a period of two years, showing that the extermination of these trypanosomes by antimony in this form is a slow process, affording the parasites in the meantime ample opportunity to cause permanent damage to the brain tissues.

The symptoms attributable to the direct toxic effect of antimony tartrate upon the human body may be classified as follows:—

- (a) *Gastro-intestinal*.—(1) Coughing and retching at time of injection, accompanied by choking sensation in pharynx. (2) Nausea and vomiting immediately after injection. (3) Delayed vomiting, commencing four to five hours after injection. (4) Acute diarrhoea lasting 24 hours.
- (b) *Cardiac* (in trypanosomiasis). (1) Cyanosis. (2) Rapid and irregular pulse.
- (c) *Cerebral* (especially in trypanosomiasis). (1) Loss of consciousness. (2) Incontinence of urine and faeces.
- (d) *Arthritic* (in bilharziasis). (1) Pain in one or both shoulders commencing one to two hours after injection. (2) Acute arthritic pain prohibiting movement in all the large joints of the body accompanied by intense lumbar pain, commencing six hours after injection and lasting for the subsequent 48 hours, noted in a recent case.

The maximum individual dose of antimony tartrate I have given is one of 2½ gr. (0.16 g.).

It is evident, then, that the discovery of an organic antimony compound, bearing the same relationship as salvarsan to arsenic, less toxic to human beings, but more specific for these protozoal parasites, should be aimed at.

Favourable Results from the Acetyl Salt of Antimony.

In 1916 Caronia¹⁶ published an account of the successful treatment of leishmaniasis in young children with a new organic compound of antimony termed acetyl-p-aminophenyl-stibiato of sodium, prepared by the chemical firm of Heyden in Dresden. The salt contained 38.5 per cent. of antimony, and was soluble (1.20) in distilled water. The maximum dosage for children under two years by the intramuscular route was 0.1 g., and in children over that age 0.15 g. The

injections were made on alternate days into each buttock—a total of 3·6 g. being given in a period of three months. In one case intramuscular abscesses following the injection were noted.

My attention was drawn to this drug by a note by Dickinson¹⁷ in THE LANCET for Sept. 6th, 1919, and since February, 1920, a supply has been procured through the good offices of Messrs. Allen and Hanburys. Considerable improvements have now been effected in its composition, with the result that a product termed "Stibenyl" has been evolved. This latter salt contains 34·3 per cent. of antimony, is soluble in ten parts of water, contains no trace of inorganic antimony, as in the first samples procured; it is non-toxic to mice in the dose of 0·2 mgm. per kilo weight, and, as far as has been ascertained at present, is easily tolerated by man in individual doses of 0·6 g. Possibly further experience will show that still larger doses may be given to man with impunity.

Treatment of an Intractable Case of Trypanosomiasis (T. gambiense) by Stibenyl.

The history of this case, which presents many features of interest, may be summarised as follows:—

E. W. S., 35, became infected with trypanosomiasis in the Belgian Congo towards the end of 1915. His illness commenced acutely on Jan. 26th, 1916, when he became unconscious, with a temperature of 103° F. Although the patient presented all the clinical symptoms of acute trypanosomiasis, yet these parasites have been very scanty in the blood during the last four years; the last occasion on which they were found in the blood-stream was in June, 1919. The cerebro-spinal fluid has been examined and found to be negative throughout. The excellent notes by Dr. W. E. Masters which accompanied the case record a general painful cervical and axillary adenitis, deep muscular hyperesthesia (Kerandel's sign), and a fugitive circinate rash, together with pyrexia, slight anaemia, and constant headaches. An intolerance to tartar emetic even in minimal doses was noted at an early date. Admitted to the Albert Dock Hospital on April 4th, 1917, he has been under observation there up to the present moment. For brief periods he has been treated as an out-patient and injected with atoxyl, but from June, 1918, to July, 1919, he was an in-patient and systematically treated with intravenous injections of tartar emetic. He was permitted to return to his home for two months, but had to be readmitted on account of recurrence of symptoms in September, 1919.

Chart of kala-azar case described in text. * Spleen puncture. Leishman-Donovan bodies found. S.C., Slight collapse. G., Gramme (stibenyl injection). I., Diagnosis made. II., Treatment commenced.

During the long period of observation he has exhibited but few symptoms of actual toxæmia. The clinical picture has been one of progressive mental and cerebral degeneration. From time to time he has exhibited a slight pyrexia of 99°-100°, but sharp bouts with rigors have been noted only after intravenous injections.

He has been extremely sensitive to antimony tartrate, and there has been no possibility of giving it in larger doses than 1 gr. at four-day intervals. The maximum dose ever exhibited was 1·25 gr. Vomiting and collapse often ensued upon the injection of 3/5 gr., and on occasions the reaction was very severe. Thus once (July 4th, 1919) he became comatose and cyanosed, with an imperceptible pulse, a condition from which he only gradually recovered after two days. Subsequently his condition became so alarming that this form of treatment had to be entirely suspended.

Towards the end of 1919 and beginning of 1920 his condition became progressively worse. He was confined entirely to bed. Muscular weakness and incoordination were considerable. His pulse frequently became feeble and irregular, and, most significant of all, he developed incontinence of urine and faeces, soon followed by epileptiform fits accompanied by screaming, enuresis, biting of the tongue, complete unconsciousness and conjugate deviation of the eyes to the right. Three of these fits were recorded—Jan. 12th, March 1st and 2nd, 1920. Each fit lasted 10-20 minutes, after which he had a paresis of arms and legs lasting for three or four days.

Up to the last date he had been treated with a total of the following drugs during four years:—55 gr. of intravenous tartar emetic; 25 gr. of soamin, intramuscularly; 48 gr. of atoxyl, intramuscularly (finally discontinued on account of threatening blindness).

On March 5th, 1920, injections of stibenyl were commenced, at first in a dose of 0·1 g. working up to a maximum of 0·3 g. From that date up to June 1st he has had a total of 4·5 g. No untoward symptoms have been noted and the improvement has been progressive. On April 21st he commenced to get out of bed and since then he has gradually accumulated strength and mental equilibrium.

so that now he has been able to leave hospital and return home for a short period. It cannot be said that his nervous system is now normal, though there is no evidence of any serious lesion. His gait is somewhat uncertain and he walks with his head bowed and the expression of his face is mask-like. All reflexes are increased, otherwise he is in good condition, he eats and sleeps well, and takes an interest in life.

Naturally it is impossible to say at present whether symptoms may not recur at some future date, but the remarkable improvement which has taken place latterly can only be ascribed to the action of this organic compound of antimony. Improvement commenced directly the drug was substituted for tartar emetic, and he was able to tolerate an injection of stibenyl at least four times as great as the maximum dose of tartar emetic ever given him, and within two months he had more antimony when given in this form (69·3 gr.) than in the whole of the previous four years.

It may be argued that the remarkable improvement which has taken place is merely one of those mysterious lucid intervals which have been noted in cerebral trypanosomiasis, but it must be remembered that, when the treatment with stibenyl commenced, a fatal termination appeared imminent; previous experience has shown that a case of trypanosomiasis which develops epileptiform fits proves invariably fatal. It is possible that the trypanosomes remained hidden in the cerebral substance in this case, as suggested by the work of Stevenson,¹⁸ and therefore could not be demonstrated in the peripheral blood.

Successful Treatment of a Case of Kala-azar by Stibenyl.

History of the case.—A Goanese lascar, aged 20, was admitted to the Albert Dock Hospital from a B.I. steamer on April 3rd, 1920, with a history of continuous pyrexia for the previous two months. On admission he was found to be severely ill with a remittent temperature of 102-103° F., and from his physical signs the illness was first thought to be pneumonia, but as the pyrexia continued after disappearance of pulmonary signs the diagnosis was obscure. Subsequently he was transferred to the Tropical Diseases Hospital, Endsleigh Gardens. Soon a swelling appeared in the left hypochondrium and extended three fingers' breadth below the umbilicus in a downward direction; posteriorly it could be mapped out in the region of the scapula; in an upward direction it dis-

placed the apex beat of the heart to the third intercostal space. Soon the tumour, which was extremely tender, could be distinguished as the spleen. The liver was enlarged slightly upwards and downwards, 1 inch below the costal margin. The blood count was at first by no means typical of kala-azar; the red cells numbered 3,500,000; leucocytes 7500, and the large mononuclears totalled but 4 per cent. The hæmoglobin was 50 per cent.

On May 8th, 1920, numerous Leishman-Donovan bodies were found by spleen puncture and were subsequently cultured on N.N.N. medium (Dr. J. Gordon Thomson). At this date the blood changes were much more characteristic of kala-azar, a leucopenia of 3500 with a mononuclear rise of 14 per cent. The pyrexia in the meantime assumed an intermittent type with frequent double rises to 103° and 104° during the 24 hours. The patient had become extremely emaciated and feeble, being hardly strong enough to turn in bed.

On May 19th, treatment with stibenyl commenced, consisting of intravenous injections on alternate days, the first dose being 0·1 g. and working up to a maximum of 0·6 g. With the exception of slight collapse following the second injection, no untoward symptoms have been noted. The improvement of the patient has been remarkable, and, after a total of 2·3 g. (35·4 gr.), his temperature has fallen to normal within 14 days (see Chart). The spleen has receded within the costal margin, and is now scarcely palpable. His general condition has steadily improved. On June 4th his spleen was again punctured, but only two Leishman-Donovan bodies were found in numerous preparations, and one positive culture was obtained. He is now up and about and gaining in vigour every day. He has had no further treatment and up to date (July 17th) has put on over 28 lb. in weight. His blood has improved considerably, the hæmoglobin now being 75 per cent., red cells 4,125,000, whites 6000, and mononuclears 4 per cent.

There are no signs of any relapse at present, but naturally it is intended to keep him under observation for a lengthy period.

Remarks.

The important points in this case are the extremely rapid action of the drug and the almost complete absence of any toxic symptoms after injection of 0.6 g. (9.24 gr.). There is little doubt in my mind that the patient has been cured, and in a remarkably short time.

Acetyl-p-aminophenyl stibiate of soda (stibenyl) is a brownish powder, easily soluble in water. The resulting solution is slightly yellow. Larger amounts, such as 0.6 g., are dissolved in 30 c.cm. of distilled water and injected by the open method. The vein should be flushed by a preliminary injection of saline. No irritating effects of the salt at the site of injection have been noted. The symptoms of a reaction following the second injection of the drug when much larger ones were subsequently tolerated with impunity may possibly be ascribed to the too rapid plasmolysis of the parasites and consequent liberation of their toxins. It is necessary that one should distinguish between a reaction of this sort and symptoms due to the toxic effect of antimony itself.

There has been a complete absence of any toxic phenomena—no vomiting, cough, nausea, or præcordial pain—as often noted after injection of the tartrate.

It is interesting to note that stibenyl is without effect upon benign tertian malaria. Two cases have been tried, and continue to have typical rigors on alternate days after 1.4 g. of the drug. Curiously enough, it appears to have no effect in bilharziasis. One case of urinary bilharziasis continued to pass living ova after 4.5 g. (68.3 gr.), but was subsequently cured with 16 gr. of tartar emetic.

While admitting that my experience has yet been small, owing to the paucity of suitable cases, the favourable results recorded, and the large doses of the drug tolerated, suggest that by combining organic chains with antimony in this manner a preparation has been evolved more specific than any yet employed for leishmaniasis. The experience already gained warrants a more extensive trial in an endemic area of kala-azar.

My thanks are due to Dr. A. L. Gregg, medical superintendent, Tropical Diseases Hospital, and to Dr. G. B. H. Hawes, formerly house surgeon at the Albert Dock Hospital, E., for the care they have taken with these cases. I must express my indebtedness to Dr. C. W. Daniels for permitting me to make use of his notes of E. W. S. Special credit is due to Mr. W. H. McCallum, not only for the enterprise he has exhibited in procuring the acetyl salt in the first instance, but also for his energy in perfecting the preparation.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: TUBERCLE GROUP.—The first annual meeting of the tuberculosis officer group, recently formed within the Society of Medical Officers of Health, was held on July 17th. Dr. F. N. Kay Menzies presided, and the business included the passing of the constitution of the group, the election of officers, and a discussion of the programme for the ensuing year. Dr. Benjamin Moore was elected president, with Dr. F. G. Caley as secretary and Dr. J. Sorley as librarian. A representative council of 25 members drawn from all parts of the country and from all branches of the work was formed. Dr. H. A. Ellis will be the chairman of this council. Meetings will be held monthly throughout the year, the presidential address being given to a meeting of the full society. Other meetings will be held at dates decided by the council to deal with discussions upon any topic of pressing interest and to receive reports from committees on special subjects. The central aim of the group is to draw together a strong body of tuberculosis workers of all kinds whose opinion when expressed may be a guide to the parent society and to the Government in the future development of the tuberculosis campaign.

SUDDEN DEATHS ON ACTIVE SERVICE.¹

BY T. H. G. SHORE, M.D. CANTAB.,
M.R.C.P. LOND.,

CURATOR OF THE MUSEUM, ST. BARTHOLOMEW'S HOSPITAL; ASSISTANT
PHYSICIAN TO THE QUEEN'S HOSPITAL FOR CHILDREN AND
TO THE METROPOLITAN HOSPITAL.

SUDDEN death in one sense is, of course, one of the necessary accompaniments of war. I do not, however, propose to speak of the military side of the subject, though many of the cases of wounds, asphyxiation from gas, and death apparently from shock only, which it became my business to investigate, were of great interest and not a little importance. I intend rather to discuss some of the cases on which I made post-mortem examinations which come within the sphere of civil practice, and I have selected those cases in which, in England, an inquiry by a coroner would have been considered necessary. In many cases a "court of inquiry" was held, though I was by no means always summoned to attend, and in others no such inquiry was deemed necessary.

Nor, again, do I propose to include a number of accidents, some of which were incidental to the war, but most of which were caused by the usual sort of carelessness which causes so many of the accidents of civil practice.

In any campaign of large dimensions it would be strange if no cases of death occurred from other causes than wounds and sickness. The number of troops engaged on the front in France formed a considerable population and a very mixed one. The circumstances were, in many places, such as to cause hardships, heavy strain, at times privation, and almost always a greater or less degree of excitement and anxiety. Even though the men had passed a medical examination on enlistment, many escaped rejection who certainly were not fit to meet these conditions, and some whom any doctor would have judged to be fit did not stand them. Men often found themselves in conditions they would never have dreamt of, and when they were passed into categories lower than "A" it was not intended that they should be in those conditions, but circumstances were constantly arising which left them in the place of "A" men, and though the vast majority were little the worse some did not pull through on account of medical unfitness.

All the cases which I propose to discuss died at a base in France, though most had at some time previously been in the fighting line, and many would doubtless have returned there. Some, however, were "B" men, and were employed on base duties. All of them occurred between January, 1917, and January, 1919.

Sudden Death from Natural Causes.

As in civil practice, the most common accompaniment of sudden death from natural causes was found to be some disease of the cardio-vascular system, and of the heart and its vessels in particular. Out of 15 cases of this character, the cause of death was referable to vascular system in 12, 3 being cases of fatty myocardial degeneration, 6 of fibroid degeneration (more or less degeneration of the coronary arteries being present), 2 ruptured aneurysms, and 1 cerebral hæmorrhage. The remaining three non-vascular causes were: (1) a cerebral tumour; (2) diabetes mellitus; and (3) "gastrostaxis."

The following is an instance of death from coronary atheroma in a young subject.

The man, aged 30, was a gunner in an anti-aircraft section, and was on duty one night when there was a raid. No bombs fell within a considerable distance of him, and his gun was not fired, but he dropped down dead at the beginning of the raid. He had extensive atheroma of his coronary arteries, but none elsewhere, and a hypertrophied heart; nothing else abnormal was found in his body. Presumably the mere excitement of the moment was sufficient to cause death in a man with arteries such as his, given the mental temperament. From an ordinary examination of his heart few during life would have suspected coronary disease; he

¹ A paper read before the Medico-Legal Society on May 28th, 1920.

probably had no murmurs, and his heart would have passed for that of the strong and active man which his age and physique suggested.

The remaining cases of this type presented no features of particular interest. They were chiefly older men, and the common trio of granular kidneys, myocardial disease, and cerebral lesions was found, one or other of the three being the immediate cause of death. There were, however, two cases in which death was due to the rupture of an aneurysm of the aorta. The usual features of syphilitic disease of the aorta were found. Both aneurysms were situated in the descending part of the aorta—that is, where diagnosis is most difficult. One was a purely thoracic aneurysm, and burst into the left pleural cavity; the other involved the abdominal as well as the thoracic aorta, and made its way into the right pleura.

Of the last three cases, in which the cause of death was natural, undiagnosed diabetes accounted for one, and very likely I should have missed it too had my sense of smell for acetone been less acute. The man was hurried down from the front line during a rush after heavy fighting, which must serve as the explanation of the failure to diagnose.

The cerebral tumour case was not without interest, for death resulted in an unusual way. The man had had no previous symptoms whatever, and suddenly fell down dead on parade one morning. He was under no unusual physical strain, but the weather was hot. A tumour, about the size of a walnut, was situated in the position of the pineal body, and had led to great and rapid distension of the lateral ventricles. The tumour had apparently arisen from the choroid plexus, and on section proved to be a psammoma.

Gastrostaxis is not a common form of death, and perhaps the name is not well chosen, but as no other cause was found perhaps it will serve, as it did at the time.

The case was that of a young man who was found dead, having vomited a great deal of blood, and a quantity was found in the stomach and bowel. No source was found of this hæmorrhage after very careful search. The mucous membrane of the stomach was a little "eroded" and discoloured over all but that portion against which the bubble of gas had lain. It was considered on this account that the erosion was a post-mortem phenomenon, and of doubtful significance. Bleeding from the stomach or bowel was not uncommonly found in France as the cause of death in cases severely wounded and very septic. In such cases, however, one or more small ulcers were always found in the stomach, small or large bowel, or even in the œsophagus. No such condition was present in this man.

Cases in which Death was due to Suffocation.

I made post-mortem examinations on eight men who died as the result of suffocation. Of these three were found face down in sand, having inhaled a certain amount of it, two died under an overturned motor-car, and three had inhaled vomited material. Probably the first three were alcoholic, though it was proved in one only. None had bitten his tongue, or showed other sign of having had a fit, and two actually had tooth-plates in position in their upper jaws. In each case sand was found in the upper air-passages, in one down to the second division of the bronchi, showing that respiration had taken place after falling. No reason was found for a fall in an unconscious state, but the general appearance of the men suggested alcohol as the most likely. I do not now remember how many of these occurred on Saturday night, but generally Sunday was the day of greatest liberty. The two under the overturned car showed no external injuries, but the body of the car was lying across their chests in such a way as to prevent them breathing. They showed the usual signs of asphyxia, and one had hæmorrhages in the base of the tongue and in the substance of the tonsils.

Of three who inhaled vomited food, two were undoubtedly alcoholic. Their stomachs were found practically empty, but both the residual food and that inhaled smelt strongly of alcohol. In one of these cases food was found in the smallest recognisable bronchi; in the other larger fragments had prevented such complete inhalation. The third of these cases was a German prisoner of war, in whom alcohol could definitely be

excluded. He was eating at the time of his death, and was believed to have had some kind of fit. All of these three cases showed cedema of the meninges, though whether this was the cause of the vomiting or the effect of suffocation is hard to say.

Deaths from Drowning.

In all, 18 bodies were brought for examination in whom death was due to drowning: 6 washed up after the sinking of torpedoed vessels, 1 fell into the river (recovered three days later), and 11 bathing accidents. All the bathing cases were seen within a few hours, but the others not for some days after death had occurred.

Apart from the immediate cause of death, there were cases—all bathing accidents—in which morbid conditions were found other than those attributable to death from drowning, and these may or may not have been contributing factors in particular instances. The coast was admittedly a dangerous one, but bathing accidents did not, as a rule, result from currents, and, for the most part, took place in comparatively shallow water. Among these secondary morbid conditions was one, which I found in three cases, and which interested me a good deal at the time, though I was unable to establish the theory I had formed with regard to it. Quite apart from the distension of the right chambers of the heart, there was great dilatation of the left side of the heart, and, in addition, pallor and friability of the muscle, without valvular disease. The three cases which showed this condition occurred within a short time of one another (at the end of July, 1918), and I believe they had all had influenza, and that the condition was attributable to that disease. In one of these cases I examined the heart muscle histologically, and found that fatty degeneration was present, though the subject was quite a young man. Of course, there are other diseases which might have produced the same result, but as influenza was prevalent at the time that seemed the most probable.

Other contributing factors in drowning cases were: old disease of the mitral valve, enlargement of the thymus gland, and in one case a small tumour at the side of the pons, a psammoma arising from the dura mater.

In cases of drowning external injuries are of importance. In the bathing cases such injuries were only trivial, occurred on the face, shoulders, and legs, and were the kind of injury that might result from dragging the dead man up the beach. Other wounds were produced prior to death, as, for instance, a severe gash on the lower jaw in a man from a torpedoed vessel. He had been several days in the water, as was evident from the condition of the skin, and the emptiness of the intestines suggested that he had not died for some time after taking to the water, but the wound was beginning to heal, and, in addition, his face was shaved to within half an inch of the wound, which clearly must have been done while still on board ship. Another had a recently healed skin wound of the head; nobody knew how he came to fall into the river, but this recent injury may have had something to do with it. A third, a member of the military police, had an old head injury, which had been trephined years before; he was drowned while trying to rescue another man.

I once had the unpleasant duty of identifying a nursing sister, who had been in the water three months after the sinking of a hospital ship. She was quite unrecognisable, and the body was largely converted to adipocere. She was identified by cutting off small portions of marking tape from various garments and putting them together. The time of her immersion was guessed from the fact that she had on her several £1 currency notes, which were of two different issues; as she was probably engaged in cross channel work she would be likely to get notes of the present issue soon after they were made current. Deductions based on these assumptions proved to be correct, and her identity was established.

As regards the morbid appearances of drowning, the classical froth on the lips, sand or weed in the trachea, and weed grasped in the hands, were met with only twice, in both instances in bathing accidents. Water

was found in the lungs in 14 out of 18 cases, and in the pleural cavities in 9. Subserous hæmorrhages occurred in 6, in the lungs in 3, in the lungs and liver in 1, and under the visceral pericardium in 2. Small hæmorrhages were found in the brain in one case.

A matter which interested me, as a novice in this kind of work, was the occurrence of water in the pleure of half of these cases of drowning. The water was generally equally distributed over the two pleuræ, and about a pint to a pint and a half in amount. It was not contaminated with blood or froth, and seemed in all respects similar to the water from which the body had been removed, but I had no means of making any analyses. The books to which I have had access refer only in a passing manner to this phenomenon, as if it were easy of explanation, or so uncommon as to need none. I searched the surfaces of the lungs carefully but could find no rupture. I distended a lung with water, but found no leak, nor did I expect to find one, for had the solution been so easy, some blood should have been mixed with the water, and further, the equal distribution on the two sides suggested a general rather than a local cause. Water was found in the pleura only in bodies which had been in the water for a considerable time, and was not found in a few who were removed soon after death had occurred. This fact suggests that the phenomenon is a post-mortem one. It occurred to me that it might be explained in this way. At a certain time after death oxidation processes consume most of the air remaining in the lung alveoli; this leads to water being sucked down into depths of the lung which were air-containing previously, and perhaps the negative pressure in the pleura leads to the transudation of this water into the pleural cavity. I do not know if this is the correct explanation, but it seems possible, and especially if the body is lying in the water, face down.

Death from Suicide.

During the two years from January, 1917, to January, 1919, I examined the bodies of 11 cases of suicide, which exemplified three methods of committing the act: 4 by shooting, 2 by hanging, and 5 cut-throats. Of the 11, 1 was an officer and the others men. As far as I could ascertain, the underlying reason in most cases was worry, sometimes about domestic affairs at home, sometimes about loss of relatives at the front, and some undoubtedly were occasioned by an order to proceed to the firing line on the following day. I was not present at the inquiries held on any of these cases, because, I suppose, the cause of death was thought to be sufficiently obvious not to need medical evidence.

A. Suicide by Shooting.

The weapons used were naturally the service rifle and the service revolver, the latter being the officer's choice. The method of using the rifle was to put the muzzle into the mouth and press the trigger with the toe. The amount of damage that can be done in a fraction of a second by this means is perfectly extraordinary, and death can hardly be other than instantaneous, for as the weapon is of necessity directed somewhat backwards the bullet often passes through the pons or medulla. In one case the bullet followed almost the middle line, passing through the pons just to the left of the falx cerebri, wounding the longitudinal sinus, and leaving the skull just to the left of the sagittal suture. Such cases illustrate very well the great "explosive" effect of a rifle bullet discharged at short range, which is much more extensive than that caused by a revolver. Any skull in which the cranial cavity is penetrated by a rifle bullet, at such short range as this, is split like an egg into a large number of separate fragments by extensive fractures which intersect one another in different directions. Two of the three who chose the rifle had their skulls broken in this way. The third aimed badly, the bullet passing through the left ramus of the jaw, the jugular bulb, and out through the mastoid process, and not entering the skull at all. The left ear was completely disorganised, and the base of the skull extensively damaged by a number of radiating fractures.

Another point of interest in cases shot through the mouth is that although the weapon was introduced between the upper and lower jaws, yet the lower jaw is generally fractured as well as the upper. I imagine the mechanism of this phenomenon to be as follows. The explosive effect of the bullet, and the large volume of gas discharged, forces the fragments of the base of the skull apart in all directions, if only momentarily. The temporo-mandibular joint is a strong one and not likely to be dislocated by rupture of its ligaments; consequently the rami of the lower jaw are separated forcibly by the explosive effect. Fracture then takes place at the weakest point, through one or other canine fossa. Frequently, too, the lower lip is split in these cases, but the sudden discharge of gas into the mouth or the recoil of the weapon may be sufficient to account for that.

One officer in this series committed suicide by shooting, but he used his revolver, the entry wound, with typical powder blackening, being in the right temple. The bullet passed through the brain from side to side, destroying the pituitary body and sella turcica on its way. The ventricles of the brain were filled with blood, though I could not show that they were actually injured; I expect they were. The splitting of the skull as a whole was not so great in this case as in those preceding, injury being more restricted to the immediate track of the bullet. (Specimens were shown to illustrate the effects of rifle and revolver discharged at close range.)

B. Suicide by Hanging.

There were two instances of this, both being in men of middle age. In both death was due to asphyxia and not to injury of the spine or spinal cord. In neither case was I present at the court of inquiry, and I heard nothing of the circumstances under which the bodies were found, but if they were completely suspended they had not dropped far. The usual statement is that the mark of the cord is far more often found above the larynx than below it, and the cord is supposed to slip up when it takes the weight of the body. In one of my cases the mark was definitely below the level of the larynx, and in the other it was across the crico-thyroid membrane. It seems to me that at whatever level the cord is applied in the first place it is bound to rise later, and whether the final mark is above or below the larynx depends on whether or not the skin sticks to the cord, as would tend to be the case if the cord were tightly fixed. In any case the skin would return towards its original position if the body were soon cut down. A point which is contradictory to this view is that there was no mark of a knot in either case. One of these men had a considerable hydronephrosis, due to the presence of several stones in one kidney.

C. Cut-throats.

In this small series of suicides there were five cases of cut-throat, which makes this method the most common. In all cases the weapon was the razor. The general character of the wound produced was not abnormal, though the extent of injury was various. All were of greater depth and extent on the left side of the neck, and all but one extended to the right side. In that case there were two cuts, both high up and fusing into one at the lower extremity. One was a small and superficial cut, and divided little more than the skin; the second was deep, laid open the larynx, dividing on its way the left external carotid artery and external jugular vein, and the left sterno-mastoid muscle as well.

One of these cases in particular interested me.

A sergeant inflicted two cuts on the left side of his neck, which joined into one large gash just above his larynx, and extended to the right side. The spine was visible through the wound. He had divided the thyro-hyoid membrane, both internal jugular veins, and both superior thyroid arteries, but had left the carotid arteries intact. The œsophagus, prevertebral muscles, and the disc between the fourth and fifth cervical vertebræ were all injured. After doing this he put away his razor into its case, and that into its usual place in his kit-bag, causing later a certain amount of trouble owing to the disappearance of the weapon.

I will only refer to one more of these cases, that of an officer who cut his throat in hospital.

He had been admitted on account of neurasthenia, and was therefore a likely subject for such an action. Of course, his revolver had been taken from him on admission, as was the rule, which probably accounts for his having chosen this means rather than shooting. He cut himself from ear to ear, dividing both internal and both external carotid arteries, an unusually high and consistently high wound. Both vagus nerves were uninjured. In this man's case the reason for his action appeared to be the fear of losing his recently won promotion if he were sent home to England, as seemed likely in view of his mental state.

The few cases I have narrated, and the larger number to which I have only alluded, make a formidable collection to compress into a short paper, but I think the number is not out of proportion to the population from which they were drawn. At Etaples there was always a large number of men in the base dépôts, as well as a considerable permanent local personnel. Probably at any one moment there were seldom fewer than 80,000 men, and often there must have been more. So far as the base dépôts were concerned, this population was constantly being drawn upon, and as constantly replaced, so that the number of men who had been at Etaples during the two years 1917 and 1918 must have been very great, and it is from such figures that any opinion as to the frequency of the various causes of sudden death must be formed. Nor do I think that my experience differs much from that of other medical officers doing similar work, but I had the good fortune not to be moved about, and this enabled me to keep my records in order.

INTRINSIC CANCER OF THE LARYNX.

IMPAIRED MOBILITY OF THE AFFECTED CORD IN DIAGNOSIS AND PROGNOSIS. OBSERVATIONS BASED ON 44 CASES TREATED BY LARYNGO-FISSURE.¹

BY SIR STCLAIR THOMSON, M.D. LOND.,

PROFESSOR OF LARYNGOLOGY AND PHYSICIAN FOR DISEASES OF THE THROAT, KING'S COLLEGE HOSPITAL.

Historical.

INTERFERENCE with the movement of a vocal cord as a symptom in certain cases affected with cancer appears to have been first noted by Lublinski² and Semon³ at about the same date. It was unfortunate that in one of his early communications Semon suggested that impaired mobility was a usual symptom and occurred at an early period of epithelioma of a vocal cord. In 1886 he wrote:—

"It is, in my experience, one of the most constant and valuable points of differential diagnosis between innocent and malignant tumours of the vocal cords, that the latter usually cause a considerable impairment of the mobility of the affected cord at a very early period—i.e., when only a small projection can be seen on the cord."⁴

Somehow the doctrine became circulated that impaired mobility was a usual symptom, and that if the cord moved freely or if the microscopic examination of a removed fragment (when this was feasible) was negative, a diagnosis of malignancy was not justified, and the case then had either to be treated as an innocent condition or left to develop. It has come my way to see no inconsiderable number of cases where this conception has led to disastrous results by losing the moment for successful operation. I regret to say that this mistaken and misleading opinion is still very widely held, although Semon himself, with more extended experience, saw the need of correcting the misconception. Twenty-one years later he formulated the following rule:—

"If the vocal cord from which a suspected laryngeal growth springs shows at an early period of the disease a defect of mobility other than due to mechanical impaction of the growth in the glottis on phonation, this sign is almost pathognomonic for the malignant character of the tumour. If, however, this sign should yet be absent when the case comes under observation, such negative evidence does by no means exclude possible malignancy."⁵

I quite agree with this rule. I would also recall that Semon only values this impaired mobility as a diagnostic aid in distinguishing between malignant and benign growths of the cords; it is of slight value in helping to differentiate epithelioma from tubercle or syphilis. When present, as Semon says, "it is a sign of great importance," and the observations here submitted will, I hope, help to establish the relative frequency and value of this symptom as an aid in both diagnosis and prognosis.

The present investigation leaves out of consideration cases which were only seen in consultation and cases which were not operated on. I thought that more valuable conclusions might be arrived at by limiting the investigation to cases which I had operated on by laryngo-fissure, in which the diagnosis in every case was confirmed by microscopic examination of the removed growth, and in which the after-history of each case has been followed up to the present date or until death.

Frequency of Impaired Movement.

I have had 44 such cases. In all of them the mobility was carefully examined and recorded on several occasions. Mere mechanical interference with the excursions of the affected cord, due to the projection of the growth, was noted when it was present, but is not recorded as an instance of impaired intrinsic mobility. Leaving such cases out of count, I find that of these 44 cases the affected cord was quite mobile in 27. In the remaining 17 cases its movements were more or less impaired, the degree varying from mere sluggishness to complete fixation. In three of these latter cases the defect in movement developed while the cases were under observation after periods of 10 days, 6 weeks, 6 months, or 9 months. In one case a feebleness in the tension and adduction of one vocal cord was noted two years before the patient returned with a subglottic malignant growth.

It was only possible to remove a satisfactory portion of growth before operation for microscopic examination in 10 out of these 44 cases. But it is noteworthy that in no less than 8 out of these 10 cases the cord moved freely. This shows that impaired mobility, when present, is a valuable diagnostic aid, as it is more apt to occur in cases where we cannot obtain a satisfactory piece of growth for examination. This is as we should expect—viz., that when a growth is embedded in a cord or tends to penetrate it the neoplasm is more likely to produce paresis than when it is projecting, or even (as in some cases) semi-pedunculated, for then a good portion (or even the entire tumour, as shown in one of my cases⁶) can be seized and removed through the mouth.

There was no mistake in diagnosis in any case. In one instance (No. 30) a very small, snow-white, papilloma-looking growth on the anterior third of a vocal cord was viewed with suspicion, as the cord was sluggish in action. The growth was removed absolutely level with the cord by the indirect method, and, after microscopic examination, reported to be a simple papilloma. Ten weeks later, as the anterior half of the cord was still less mobile and the surface of the cord had not healed over with a smooth, clean cicatrix, I proceeded to a laryngo-fissure. The growth in the cord, when exposed, was so small and uncertain in character that it was only after consulting the patient's son and family physician, and after their agreeing to removal of a growth of merely suspicious character, that I completed the excision of the cord. On examining this microscopically Dr. C. Fletcher reported that "the features are suspicious but the evidence insufficient to warrant a definite diagnosis of malignancy." The slides were then sent to Professor Shattock, who reported:—

"At the spot of thickening there is a distinct, somewhat wedge-shaped ingrowth. The superficial cells of the thickening are keratinizing. The epithelial cells of the ingrowth have lost their typical characters, and have, at the margin, wandered into the circumjacent connective tissue. My diagnosis is—a very early stage of carcinoma."

⁶ StClair Thomson: Intrinsic Cancer of the Larynx; Complete Excision Apparently Effected by Endolaryngeal Operation. THE LANCET, May 30th, 1914.

This case is quoted to illustrate the anxieties in the diagnosis of some of these cases, the difficulties of the morbid histologist, and the value of impaired mobility, when present, in helping the diagnosis.

Valuable in Prognosis.

As to its value in prognosis:—Of the 27 cases with a mobile cord 21 are alive and free from local recurrence. Two have had local recurrence, 1 is dead from cancer in another part of the body, and 3 have died from other causes.

But of the 17 cases with impaired movement only 7 are alive and free from recurrence. Five have died of local recurrence: 1 died of recurrence in the glands; 1 from hæmorrhage following operation; and 3 have died from other causes. It is evident that when a case of intrinsic laryngeal cancer presents itself the prognosis is decidedly less satisfactory—so far as regards the ultimate result of a laryngo-fissure—if the cord is paretic or fixed. In such cases it would be well to consider carefully whether the usual laryngo-fissure is adequate, or whether some more extensive removal should not be initiated at once.

Conclusions.

1. Impaired mobility of a cord is not a necessary or frequent symptom of intrinsic cancer of the larynx.

2. It is, in fact, only met with in a minority of cases presenting themselves for diagnosis.

3. It is more apt to be met with in an early case when the growth is embedded in the cord or growing into it than in a distinctly sessile or even pedunculated tumour. It is also more usual with growths situated on the inner surface or the subglottic area, than with those seated on the upper surface of the cord. Otherwise, fixation indicates an advanced case.

4. When present it is a very valuable symptom in distinguishing a malignant from an innocent tumour. It is of little value, and may even be misleading, in diagnosing a malignant growth from a tuberculous or syphilitic deposit.

5. While in some cases it may be necessary to postpone a diagnosis in the absence of this symptom, yet, as it is desirable to avoid any delay, we may have to rely on inspection, the age, sex, history, and progress of the case, and the exclusion of other possibilities. The help of microscopic examination of a removed portion is only available in a small number of cases (10 out of 44).

6. As regards prognosis, it is an unfavourable symptom.⁷

THE PSYCHOLOGICAL ASPECT OF THE EFFORT SYNDROME.

BY MILLAIS CULPIN, M.D. LOND., F.R.C.S. ENG.,
LECTURER ON PSYCHONEUROSES TO THE LONDON HOSPITAL.

On taking a general view of the war psychoneuroses we find that they reproduced all the symptoms ascribed to functional nervous disorders in civil life; very few symptoms were observed that had not been seen before, and conversely, what had been previously described could be illustrated. We find the usual bodily manifestations of hysteria: paralyses, contractures, incoördinate gaits, tremors, aphonia, mutism, blindness, deafness, fits, fugues, and somnambulisms; and on the purely mental side we find depression, irritability, anxiety, loss of volition, and psychasthenic symptoms such as phobias and obsessions.

The apparent absence of any well-known symptom group calls for explanation, and the following extracts from Osler's text-book on "The Principles and Practice of Medicine" (fourth edition, 1901) refer to conditions which are not found, prominently at any rate, in accounts of the war psychoneuroses. On p. 1118 we read, under the heading of hysteria:—

"Rapid action of the heart on the slightest emotion, with or without the subjective sensation of palpitation, is often a source

⁷ Six patients were shown on whom laryngo-fissure had been performed at varying dates up to seven years ago. One case had presented himself with complete fixation of the infiltrated cord, but was free of recurrence three years after laryngo-fissure.

of great distress. A slow pulse is less frequent. Pains about the heart may simulate angina, the so-called hysterical or pseudo-angina, which has already been considered. Flushes in various parts are among the most common symptoms. Sweating occasionally occurs."

On p. 1126 we read, concerning neurasthenia:—

"In other cases the *cardio-vascular* symptoms are the most distressing and may occur with only slight disturbance of the cerebro-spinal functions, though the conditions are nearly always combined. Palpitation of the heart, irregular and very rapid action (neurasthenic tachycardia), and pains and oppressive feelings in the cardiac region are the most common symptoms. The slightest excitement may be followed by increased action of the heart, sometimes associated with sensations of dizziness and anxiety, and the patients frequently have the idea that they suffer from serious disease of the organ. Attacks of pseudo-angina may occur.

Vaso-motor disturbances constitute a special feature of many cases. Flushes of heat, especially in the head, and transient hyperemia of the skin may be very distressing symptoms. Profuse sweating may occur, either local or general and sometimes nocturnal.

Cardiac Patients with Psycho-neuroses.

If we look for symptoms corresponding to these descriptions we find them recorded, not among the psychoneuroses of war, but among those cases known as soldier's heart, the effort syndrome, or disordered action of the heart (D.A.H.).

Some quotations from the Report to the Medical Research Committee¹ on the subject will show this correspondence of symptoms.

P. 5.—"Pain is an inconstant but frequent symptom and one which, when present, varies in degree from precordial discomfort to pain of anginal distribution; it is especially associated with exercise....." "Giddiness is almost constant, and is associated with change of posture and with effort. Attacks of fainting are less common, and their associations are less clearly defined."

"Palpitation..... is very frequent, especially during and after effort." "Coldness of the hands and feet, sweating of the hands and feet, or excessive sweating of the body generally are very common."

P. 6.—"It is the custom to find relatively rapid heart action in all circumstances, but the chief difference between the patients and healthy subjects in this respect is an exaggerated response of the heart-rate to emotion, exercise, and posture."

"Intermittence of the heart, or an irregularity which clearly accompanies respiration when this is deepened by request, is not uncommon."

P. 25.—"In many of the patients flushing is easily provoked by relatively slight causes."

The similarity of the symptoms is insufficient to do more than suggest a resemblance between "nervous" and "D.A.H." cases. Osler obviously regarded the troubles he described as only a part of the more important nervous condition, and if we search the Report we find that nervous symptoms are in no wise lacking, for throughout it are scattered observations on the nervous aspect of the cases which only need a little emphasis to carry the resemblance to the point of identity. Some of these observations are:—

P. 5.—"Exhaustion is an almost constant symptom; it is usually provoked by sustained effort, but in a degree far in excess of that due to fatigue in healthy men. In severe cases it is a continuous symptom, and is not only physical but is equally mental." "Head-ache, which is almost constant, frontal or throbbing in type, often severe, and usually an after-symptom of exercise." "Irritability of temper, sleeplessness, inability to fix attention, shakiness, flushing, are common, especially the last three named." (P. 7.) "Many of the patients acquire the diagnosis of *neurasthenia* from time to time qualified by the phrase 'of the vaso-motor type'; especially is this so when brisk reflexes are associated with mental irritability or exhaustion."

(P. 59).—"Though emotional disturbances are more common than in healthy people, being exhibited in rare cases to a very abnormal degree, and though irritability of temper, lack of concentration, apathy, and depression are frequent symptoms, yet these disturbances are less pronounced than in patients who are commonly classed as neurasthenics."

It may be assumed that these observations were made without any deliberate psychological investigation. Nervous patients have a tendency, unrecognised by themselves, to stress their bodily symptoms and to remain silent about their painful thoughts and emotions; for this reason the deeper troubles associated with the effort syndrome may escape notice; the dyspnoea, faintings, palpitation, and heart pains become essential symptoms, and when accompanied by a rapid pulse form a picture which is regarded as complete. If the patient is asked about nervous symptoms he may, especially if he is of a temperament inclined to hysteria, deny anything except his heart trouble; but as a rule he will relate symptoms ranging from nervousness in traffic, ready starting at noises, depression, irritability, or insomnia, up to those of a deep-rooted psychasthenia, with phobias, obsessions, unreasonable feelings of

¹ Special Report Series, No. 8. H.M. Stationery Office. 1918.

incompetence or uncertainty, or even that sensation of the strangeness of the world which is described as a "loss of the function of the real."

At this stage of investigation it is easy to convince the patient that his symptoms are not due to heart disease but are only part of a nervous condition; the explanation is likely to be rejected if one tries to assure him that his heart is healthy without this preliminary inquiry into his mental state.

Psycho-neurotics with Associated Cardiac Symptoms.

Approaching the subject from the other end of the scale of symptoms, we find that men whose nervous state has been regarded as of primary importance—for instance, those diagnosed "shell shock"—show in a large proportion the rapid pulse of the effort syndrome, and if the disabilities allow of exertion the patients complain of the symptoms associated with that diagnosis; it is very common to obtain a history of previous admissions to hospital for some kind of heart trouble. (This view must be compared with that quoted above from p. 59 of the Report.)

Sensations are described in terms of heart or emotion, according to the way in which the man has been led to regard them. There are medical men who think of phobias as text-book curiosities and fail to recognise the significance of such complaints as faintness and palpitation, generally accompanied by shakiness, when the patient is in a train or a crowd, though if the man is questioned he will often describe a feeling of anxiety or fear, of which the cardiac symptoms are only the manifestations. The fainting attacks of the sufferers from the effort syndrome are really attacks of anxiety and primarily of emotional origin, being identical with the "nervous" attacks of the sufferer from an anxiety condition. There is no line to be drawn between those attacks and others, usually called hysterical, in which emotion finds expression in motor activity.

I cannot agree with the view given on p. 7 of the Report, where we read on the subject of terminology:—

"From the standpoint of military service it is a matter of indifference what term is employed providing that the method of dealing with the patients is not thereby influenced. But the diagnosis of neurasthenia has this defect, and the latter is not counterbalanced by an appreciable insight into the pathology of the condition."

It is essential that the man should recognise his condition; he is suffering from something, and until he realises what it is he will insist upon fixing his attention on the heart symptoms. It follows that I do not regard a diagnosis of D.A.H. as responsible for the symptoms in any large number of cases; if the man's attention had not been directed to his heart he would have found some other point of fixation for his troubles. I would illustrate this by reference to a recent inquest upon an ex-soldier who, discharged for valvular disease of the heart, had worried about his condition, and eventually committed suicide. Post-mortem examination showed a healthy heart, and the coroner, according to a newspaper report, said the poor man had been condemned to death by an ignorant army doctor. This judgment was not well founded; suicides of ex-soldiers suffering from depression are too common, and this man's nervous condition both produced the heart symptoms—probably the effort syndrome—and led to the suicide. A healthy young man does not commit suicide because he is told he has heart disease, and if this man had been diagnosed as suffering from neurasthenia or shell shock the end would probably have been the same, and no one would have been blamed for it.

I have met a few men without anxiety symptoms who had been told they had heart disease, perhaps on account of a functional murmur. Their attitude is usually quite reasonable, and although they logically attach value to the diagnosis it is possible to alter their belief by ordinary argument. In pensioners of a certain temperament, however, there are obvious reasons why a diagnosis of "heart trouble" aids a resistance against any view but that of organic disease, and if a man is tending towards an anxiety state it is plainly unwise to provide him with a diagnosis which will serve as a further source of anxiety.

Treatment must be directed towards the nervous condition and not to the heart symptoms. One method

to this end was used in special heart hospitals when the "heart" condition was attacked by reassurance and persuasion combined with exercise; this method is a very old one as applied to the psychoneuroses.

The Psychological Processes.

A few words about the psychological processes concerned and the way in which they influence symptoms will aid in understanding the question of treatment. In war cases the processes are more easily revealed than in cases arising in civil life, and opinion is now crystallising round the view that the psychoneurotic symptoms depend upon a repression, or loss of memory, of incidents of a strongly emotional content. Though lost to consciousness these memories produce and maintain symptoms; they may produce stammers or tremors, hysterical fits, or paralyses and contractures. These bodily symptoms may also serve to gain an end otherwise unattainable by the patient—such as avoiding military service or some difficulty of adaptation—and the knowledge of this end may be the repression chiefly concerned; this "secondary function" is characteristic of the hysterical type of patient, in whom the emotional content of the repression may be so well fixed by the symptom that he shows no other signs so long as he is allowed to retain his bodily disability. This type passes gradually into that in which no secondary function is conceivable, and the disturbances are supported only by the emotional content of the repression, which shows itself in an anxiety state, accompanied or not by bodily symptoms.

In this latter group are men whose repressions find vent in phobias, anxiety attacks on slight or no provocation, fainting spells, or apparently causeless fear and apprehension. The patients are in a permanent emotional state.

The Connexion Explained.

So far I have presented conclusions supported by a considerable weight of experience and based upon psychological investigations carried out by many workers. Their application to explain the associated cardiac symptoms contains a speculative element. Certain signs, such as fine tremors of the hands and closed eyelids, together with a nystagmoid twitching of the eyes when lateral movements are tested, are associated with that muscular lassitude of which so many complain, and suggest a lack of tone dependent upon interference with the endocrine glands. Terror is accompanied by an increase of the adrenalin content of the blood; a continued state of emotion may, by affecting the ductless glands, produce the muscular signs above described, as well as the symptoms of the effort syndrome which accompany them. Whatever their cause, these symptoms differ from the purely hysterical ones in being unrelated to volitional control.

We can picture disturbance taking place at different levels of the nervous system; interference with the cortical centres gives us motor and sensory changes, generally called hysterical, as well as purely psychical ones. These we may call psychoneuroses, the more suitable word "psychosis" being already appropriated to indicate insanity. When the thalamic centres are involved—whether by over-stimulation or by loss of cortical control—excessive response is shown by ready starting at ordinary noises or by exaggerated reflexes, as when a tap upon the patellar tendon is followed by a general muscular reaction of the whole body. At a lower level the autonomic functions are disturbed; this is shown by increased sweating and other altered skin reactions, and by interferences with digestion. Here we may place the altered endocrine functions that affect muscular tone and maintain some of the symptoms and signs of the effort syndrome. The word "neurosis" may perhaps be properly applied to these changes at the lower levels of the nervous system, though they cannot be separated from the psychoneuroses as regards either cause or treatment.

If the psychoneuroses are accepted as due to repressions, then treatment should be directed to bringing the repressed memories into consciousness. It is beyond my present purpose to discuss how this can be done, but the effect upon the heart of treatment

directed towards the underlying condition is illustrated by a man who suffered from a severe anxiety state and had a pulse-rate of 160 (taken, it is true, during an examination by a pensions board) with the usual symptoms of the effort syndrome. He had a loss of memory for almost every emotional experience during two and a half years of fighting, and as the memories were revived with due emotional expression his pulse became less frequent and after nine interviews reached and remained at the rate of 76 per minute; his other symptoms showed a corresponding improvement.

On p. 23 of the Report is described a severe fainting fit in a young man who presented "the characteristic signs of toxic debility." The fit resembled closely those in a patient of mine whose frequent "heart attacks" were so alarming that he was placed upon the "dangerously ill" list; the attacks ceased after the revival of the one incident which they symbolised and which had been completely forgotten. Syncopal attacks in patients with repressed war experiences (and these patients include most of those who were subjected to the stress of actual warfare) can often be traced to definite repressions, as in the last example, and are benefited by their revival. Long-standing conditions, aggravated or not by army experience, present greater difficulties, and it is not practicable to treat by methods of mental exploration any large number of them. Even in these a recognition and explanation of the real condition is preferable to allowing the patient to go through life with a belief in the organic cause of his symptoms.

The question may be raised whether the symptoms in valvular cases are sometimes due to an anxiety condition; such a hypothesis would satisfy the problem raised in the Report in regard to the onset of symptoms after shell shock in patients with pre-existing valvular lesions. The existence of a symptomless and unsuspected organic lesion would not protect a man from a psychoneurosis, and the cardiac symptoms that arise would be attributed to the lesion, though they may be in no way related to it.

The possibility of other combinations must be considered. There may be a group of cases in which dyspnoea, cardiac pain, and palpitation persist indefinitely and depend upon physical causes, although no signs of heart or lung disease ever become manifest; there are certainly cases in which those symptoms are the first indications of organic disease; an anxiety state may exist in addition, just as it may in combination with other diseases. But the majority of cases found amongst pensioners and diagnosed D.A.H. are entirely of psychogenetic origin. If this fact could be generally recognised it would aid in the restoration to social usefulness of some of the men who now regard themselves as permanent invalids.

SYMBIOTIC GROWTH OF *B. PROTEUS* AND *B. TUBERCULOSIS*.

APPEARANCE OF AN ACNE-LIKE ORGANISM.

By E. T. THOMPSON,

MINISTRY OF PENSIONS HOSPITAL, ORPINGTON.

(With a Note by R. A. O'BRIEN, M.D.)

SOME years ago I commenced a series of experiments bearing on the symbiotic growth of organisms in the mass of bacterial growth in the intestine. A five months' glycerine-veal broth culture of *B. tuberculosis* (bovine) was inoculated with a laboratory strain of *B. proteus vulgaris*. The proteus grew quite luxuriantly and no change in the morphological characters of the organisms could be observed on the seventh day. On the twelfth day a marked yeast-like odour was noticed on opening the incubator, and, on microscopical examination of the mixture, it was found to be crowded with a diphtheroid organism. Nothing further was done with this mixture as I presumed that the presence of this third organism was possibly the result of a contamination.

A repeat experiment was performed, using every precaution against contamination. Four strains of *B. tuberculosis hominis* and one strain of *B. tuberculosis* (bovine) were grown on large tubes of glycerine-brain

agar for one month, after which time sufficient glycerine-veal broth was added to cover the growth, and inoculated with *B. proteus*. In all the mixtures the diphtheroid organism described in the first experiment was observed at the end of ten days. The yeast-like odour is apparently characteristic of this remarkable phenomenon, as it was noticed in all the tubes. Furthermore, the dense turbidity due to the growth of *B. proteus* had disappeared on the formation of this new organism. Subcultures made on surface agar showed no growth at the end of seven days, the proteus having died out. In stab glucose-agar, inoculated from the mixture, a growth was observed at the end of three days, which was strictly anaerobic. The growth was a compact one, starting about half way from the surface of the glucose-agar. On microscopic examination it was found to be the diphtheroid organism observed in the mixtures.

Morphologically and culturally this organism is identical with the acne bacillus.

With subsequent experiment it was found that the evolution of this organism was not constant, and up to the beginning of 1914 97 experiments with tubercle had been performed under varying conditions in order to determine the most suitable conditions under which the phenomenon occurred. 62 per cent. of the experiments were positive and the most favourable conditions seemed to be glycerine-veal brain agar cultures of tubercle to which 5 per cent. glycerine-peptone water to cover growth had been added. Temperature 37° C. The evolution of this organism has occurred in every strain of tubercle which has been subjected to this treatment at different times both in culture and in tissue—i.e., seven strains of human, six strains of bovine, one strain of avian, and one strain of piscine *B. tuberculosis* in culture. Three experiments were performed with tuberculous tissue; two were positive and one suspicious.

Experiments were carried out on organisms more or less allied to *B. tuberculosis* with positive results—i.e., *Streptothrix actinomyces*, *Str. birt* and *leishman*, the bacillus of Johne, and one of three strains of acid-fast bacilli isolated by Tobler.

A few animals (guinea-pigs and mice) were inoculated by Dr. O'Brien with living cultures of the new organism isolated from the tubercle + proteus mixtures, but the results were variable. The animals were killed and a diphtheroid was generally found in some of the organs. Exhaustive controls were carried out on all the organisms under experimentation in order to eliminate, as far as possible, any suspicious members of the group. The cultures were observed under aerobic and anaerobic conditions with and without the addition of glycerine-peptone water.

The work had not proceeded far when the proteus was started from a single organism by the capillary tube method. Many organisms remote from the tubercle group were grown in symbiosis with proteus, but in none of these, or other controls, did the evolution of this diphtheroid occur. The morphological characters of the organism varied from the almost coccoid diphtheroid to the long, club-shaped forms one sees in old broth cultures of *B. diphtheria*; this was especially noticeable with the organism isolated from the actinomyces + proteus mixture.

Repeated Experiments.

At this time several factors over which I had no control, and later the outbreak of war, prevented further work in connexion with the subject until quite recently, when I determined to repeat some of the experiments with the cultures to hand in my own laboratory. All the cultures in this later experiment were from other sources than those used at the Wellcome Physiological Research Laboratories. One strain each of *B. tuberculosis*, human and bovine, actinomyces bovine, a streptothrix isolated from a case at Westminster Hospital, and *B. smegmatis* were grown on glycerine-brain agar, the growth, covered with 5 per cent. glycerine-peptone water, and inoculated with *B. proteus*. In every tube the diphtheroid organism was observed in from 7 to 14 days.

The object of this paper is simply to place on record the work which has been done, together with the

results, without comment, as it would be premature to draw definite conclusions with such meagre data on a matter of such great complexity. However, in view of the last results there is justification in assuming that the appearance of this third organism is not due to a contamination, and that it strengthens the theories, so often hinted at throughout bacteriological literature, that the acid-fast organisms and the streptothrices are closely related, and that at certain phases of their existence no sharp line of demarcation exists.

My thanks are due to Dr. H. J. Südmersen, Dr. O'Brien, and Mr. A. T. Glenney, of the Wellcome Physiological Research Laboratories, and to Professor R. T. Hewlett for their help and practical interest in this work.

NOTE ON MIXED CULTURES.

By R. A. O'BRIEN, M.D.,

WELLCOME PHYSIOLOGICAL RESEARCH LABORATORIES.

Several years before the war Mr. Thompson stated that while working as chief bacteriological assistant in these laboratories, he had inoculated cultures of *B. tuberculosis* with *B. proteus*, and that an acne-like organism had appeared in the tubes after the death of the *B. proteus*.

I was asked to investigate the matter, and made some mixed cultures. The phenomena described by Mr. Thompson occurred in one of the tubes of an early series. Several weeks after the mixed culture was made the *B. proteus* could no longer be recovered by subcultures, and there were present in large quantities strictly anaerobic bacilli which were Gram-positive, not acid-fast, and, morphologically, closely resembled the acne bacillus. I made several hundred experiments with different strains of *B. tuberculosis*, using cultures of *B. proteus* plated many times, and also a culture obtained from what appeared under the microscope to be a single *B. proteus*. In three of these experiments the second anaerobe made its appearance. Every ordinary bacteriological precaution to eliminate the possibility of contamination was used; the anaerobe could not be seen in smears made either from the separate cultures of *B. proteus* or *B. tuberculosis*, or from mixed cultures during the first week of incubation.

This anaerobe is practically unknown as a contamination in the multitude of cultures and sterility tests made in these laboratories in connexion with other work. Pure cultures of the anaerobes were injected into small animals; these remained healthy and were eventually killed. I was not satisfied that any pathological changes were present, though the bacillus was found aggregated in some of the glands and organs. Large doses of the organisms were injected into several guinea-pigs. It was not possible to demonstrate any alteration of resistance to infection by cultures of *B. tuberculosis*, which were subsequently injected.

The anaerobe never appeared in my cultures of *B. proteus* with various Gram-negative organisms, nor in those containing *B. tuberculosis* and Gram-negative organisms other than *B. proteus*.

Neither Mr. Thompson nor I could arrange the conditions of the cultures so as to ensure the appearance of this organism in every experiment. The results were very irregular, some series of many tubes failing entirely to give the results sought for. It was felt that it would be undesirable to publish these results unless one could describe the conditions with sufficient accuracy to enable the experiments to be checked by other workers. With the hope of being able, eventually, to control the conditions, the work was continued as opportunity offered, until the war stopped it. Mr. Thompson has now left these laboratories, and wished to publish the preceding note.

The change from the aerobic acid-fast organism to the anaerobic non-acid-fast Gram-positive one appears to be so opposed to the whole of general experience that one naturally inclines strongly to the assumption that the organism was a contamination. Yet the organism has never been found as a contamination in thousands of sterility and other tests made here in the course of many years, and it made its appearance despite every ordinary bacteriological precaution against contamination.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

LARYNGOLOGICAL CONGRESS.

THE second Summer Congress held by the Section of Laryngology took place on June 24th and 25th under the chairmanship of Mr. MARK HOVELL, and was in every way a success. A valuable aspect of the Congress was the full discussion of subjects intimately associated with the specialty—such as "Cancer of the Throat"—which the ordinary clinical meetings only incidentally raise in connexion with particular patients and specimens. Important addenda were a museum of pathological drawings and specimens (which was kept open for a week) and an exhibition of surgical instruments and drugs. There were a number of American and European visitors at the meetings.

Sir CHARTERS SYMONDS read a paper on Total Laryngectomy, in which he dealt in detail with the indications for operation, the special dangers, and how they could be met. He laid particular emphasis on the after-treatment, designed to ensure the greatest possible comfort to the patient and his participation, as fully as might be, in active pursuits. If the patient could breathe sufficiently well to carry him through the operation the speaker dispensed with preliminary tracheotomy. He showed two patients who were able to make themselves clearly heard years after the operation.

Sir ROBERT WOODS (Dublin) gave his experience in 25 cases, and described the after-treatment. Drainage of the pharynx afterwards he regarded as very important. He preferred total laryngectomy to attempts to get the growth away by median thyrotomy.

Sir WILLIAM MILLIGAN did not do tracheotomy beforehand unless it was urgently needed. He laid special stress on a thorough examination of the region with the œsophagoscope before deciding on the operation, as it was sometimes found in this way that the growth had a much greater extension downwards than had been suspected. The difficult part of the operation was the suturing of the mucous membrane of the pharynx.

Dr. F. LEMAÎTRE (Paris) favoured tracheotomy 14 days before the major operation in these cases. He used local anaesthesia.

Sir JAMES DUNDAS GRANT pointed out the type of cases in which simple thyrotomy sufficed for the removal of the malignant disease, and expressed the hope that this operation would retain its place for suitable cases.

Dr. J. J. KILLEEN (Chicago) said the results in the kind of cases under discussion which he had seen in America, where they were usually dealt with by the general surgeon, were very poor. There was now a growing tendency to refer them to the specialist, especially in New York.

Dr. IRWIN MOORE said that 30 years ago of 163 cases 41 per cent. died from the operation and 28 per cent. more were dead within a year.

Mr. WILFRED TROTTER discussed a measure of pharyngotomy for the exposure of large growths of the epiglaryngeal region; it consisted of a minute examination of the various routes and their suitability in particular cases. The contribution was fully discussed, and Mr. Trotter further elaborated his methods in his reply.

Dr. LOGAN TURNER gave a series of illustrations of carcinoma of the post-cricoid region and upper end of the œsophagus, and submitted tables of sex incidence and age of onset. He also dealt with the symptoms according to the situation of the growth.

Mr. E. D. DAVIS read a paper on the Early Diagnosis of Carcinoma of the Oral and Laryngeal Pharynx, in which he drew attention to the value of a direct examination, either by suspension laryngoscopy or by means of the œsophagoscope.

Sir STCLAIR THOMSON followed with a contribution on the Significance of Impaired Mobility of the Cord in the Diagnosis and Prognosis of Intrinsic Laryngeal Cancer, which appears this week in our original columns.

Dr. A. BROWN KELLY read a paper on Oesophageal Obstruction due to Hypertrophy of the Cardiac Sphincter, with details of a case.

Sir WILLIAM MILLIGAN contributed a paper on the Removal of Foreign Bodies which became Impacted in the Food- and Air-passages, based on a large personal experience. He emphasised the importance of coöperation in these cases between the laryngologist and the radiologist, though a negative statement by the latter should not necessarily be accepted as conclusive.

Dr. P. WATSON-WILLIAMS entered into the question of Latent Sinusitis in Children, the symptoms of which were essentially similar to those of infected tonsils and adenoids, chiefly recurrent nasal catarrh, buccal respiration, catarrhal deafness, aprosexia, mental backwardness, and chronic sepsis. He described the methods of examination in arriving at a diagnosis and gave full details of an illustrative case.

Mr. H. LAWSON WHALE submitted a short thesis on Per-nasal Dacryocystostomy, showing the importance of attacking the sac itself, not the nasal duct. Acute empyema he regarded as a contra-indication of the operation. In his 25 cases, 63 per cent. were cured, and 12 per cent. partially so.

Dr. IRWIN MOORE's paper on Angeliomata of the Larynx consisted of a summary, in easily referable form, of all the recorded cases.

Mr. W. M. MOLLISON's concluding paper dealt with tonsillar infection as a source of various systemic and other diseases, such as endocarditis, myocarditis, rheumatoid arthritis, fibrositis, myositis, and "neuritis," also such skin affections as alopecia areata, lupus erythematosus, and psoriasis. In all the cases examined a streptococcus was found. About 80 per cent. of the cases treated by tonsillectomy were cured, and the remainder were left in statu quo.

On Friday afternoon a series of demonstrations were given, and in the evening the usual clinical meeting took place, when many patients were shown and their conditions discussed.

The authors explain their results on Crile's kinetic theory of shock, attributing all the phenomena to exhaustion following attempts on the part of the organism to escape from noxious influences; they assume an intracellular acidosis, but their theories are often strangely inconsistent. They consider nitrous oxide anaesthesia a partial substitute for sleep, and yet find that, in the worst cases of exophthalmic goitre, it is best to keep it so light that analgesia alone is caused without loss of consciousness. Assuming that nitrous oxide acts by interfering with the use of oxygen by the brain cells, they argue that the formation of acid substances in the brain is thus prevented; it is not clear why the opposite should not be the truer deduction. A crossed circulation experiment is reported in which the only proof of the occurrence of shock in either animal seems to have been the finding of certain histological differences in the nerve cells, these changes being themselves controversial. The result obtained would normally be expected from the experiment, even if these changes had nothing to do with the cause of shock. The photo-micrographs intended to demonstrate the cell-exhausting theory are not very convincing.

According to these authors "shock is a loose and unscientific term. We realise that it might well be dispensed with and the word exhaustion substituted." This is mostly true of shock as described in this book, but is by no means true of all shock. The term exhaustion might well be used for the post-operative reaction, which is largely of this origin, so as clearly to distinguish it from other conditions, such as the surgical shock of immediate onset after a severe injury, so often seen on the battlefield.

So well does Dr. Crile put his theories into practice that to anyone who has seen his wonderfully clean knife-work and bloodless surgery, and Miss Hodgins's excellent anaesthesia, the absence of post-operative reactions in his patients seems only natural. Whatever theory of shock may be held, this joint production is a valuable book, with which all surgeons should make themselves familiar.

DER KROPF DER WEISSEN RATTE.

Beitrag zur vergleichenden Kropf-forschung. Von Prof. Dr. Th. LANGHANS and Prof. Dr. C. WEGELIN. Berne: Paul Haupt. 1919. Pp. 131. Fr. 14.

THIS small volume, published from the Pathological Institute of the University of Berne, and carrying on its title page the name of the late Professor Langhans as part author, is a report of experiments instituted in 1911-13 by the Swiss Goitre Commission. The experiments were designed more particularly to test Bircher's hypothesis that the endemic occurrence of goitre is associated with definite geological formations, and that goitre is due to some toxic substance derived from such geological formations introduced into the body in the drinking water. Bircher claimed that it was possible to produce goitre experimentally in white rats, monkeys, and dogs by supplying them with water from certain districts.

The present report consists chiefly of a detailed histological description of the thyroids of about 120 rats which had been kept in different localities in Switzerland on similar diets but different water. The results show that the drinking-water hypothesis cannot be accepted as an adequate explanation of the aetiology of endemic goitre, and that it is even doubtful whether it has any connexion therewith. In one district (Kazis), where goitre is endemic, the six rats receiving the local water all developed a typical goitre; but unfortunately for the hypothesis 10 of the 11 control rats which had received milk instead of water also developed goitre. Again, a series of rats kept by Kocher in Berne, and supplied with water from a certain district, showed marked goitrous changes in the thyroid; but another series kept in a different institute and receiving the same water showed hardly any changes at all. It is interesting to note that Bircher's hypothesis has also been tested recently in the Argentine, where goitre is endemic in certain regions. A recent volume of the "Revista del Instituto

Reviews and Notices of Books.

SURGICAL SHOCK AND THE SHOCKLESS OPERATION THROUGH ANOCI-ASSOCIATION.

Second edition. By G. W. CRILE, Professor of Surgery, Western Reserve University, &c.; and W. E. LOWER, Associate Professor of Genito-Urinary Surgery, Western Reserve University. London and Philadelphia: W. B. Saunders Company. 1920. Pp. 272. 21s.

THIS book has been entirely revised, rewritten, and brought up to date in the light of war experience. The authors have aimed at presenting concisely the principles and practice of anoci-association methods, which they now designate by the term anociation; they do not discuss the various theories of shock, but merely state dogmatically their own position. The book contains a large amount of excellent advice on surgical technique, including many hints on the conduct of special operations derived from the authors' own abundant experience. The authors may justly speak with authority on the technique of avoiding post-operative shock by reduction of trauma, a method which will always be associated with the name of Crile. They advocate dissection by the knife rather than with blunt instruments, and emphasise the importance of avoiding psychical strain; treatment by blood transfusion is described in detail. Convincing statistics are given to show the superiority of nitrous oxide and oxygen anaesthesia over all others in serious cases, especially when combined with regional infiltration with novocaine.

Bacteriologico''¹ contains a paper by Wernicke, in which he dismisses Bircher's hypothesis as untenable. It would appear, therefore, that the drinking-water hypothesis must be relegated to the limbo of ingenious speculations which have had the misfortune of not fitting in with the facts.

The authors review critically the various hypotheses which have been put forward to explain the condition, and very cautiously—caution like goitre seems to be endemic in hilly countries—they refuse to accept any of them and suggest that more than one factor is concerned in the ætiology of endemic goitre, while commenting on the certainty with which potassium iodide in minimal quantities prevents it. One naturally reads with special interest their reference to McCarrison's work. They criticise his conclusions on the ground that feeding with fæces has in the hands of other workers failed to produce goitre. That criticism is not very convincing, since the bacterial flora in the intestine is a variable factor and is greatly influenced by the diet. They admit that the therapeutic results of intestinal antiseptics are a strong confirmation of McCarrison's views. In an appendix they deal with the contention of Chagas that the endemic goitre of Brazil is due to an infection with *Trypanosoma cruzi*. Rabbits and guinea-pigs infected with these trypanosomes showed no changes in their thyroid glands. The special form of goitre described by Chagas is probably an endemic goitre complicated by a superimposed trypanosome infection.

This careful and painstaking investigation is illustrated by numerous figures and supplied with a full reference to the literature of the experimental production of goitre. It seems a pity that no observations were made on the suprarenal glands of the goitrous animals. The testes, ovaries, pituitary and parathyroid glands are stated to show no abnormalities, but none of these organs are functionally as closely related to the thyroid as is the suprarenal gland.

THE SYSTEMATIC TREATMENT OF GONORRHOEA IN THE MALE.

Second edition. By NORMAN LUMB, O.B.E., M.B., B.S. London: H. K. Lewis and Co., Ltd. 1920. Pp. 123. 5s.

In this second edition of a work published first in 1917 the author has included recent developments and improvements in diagnosis and treatment. The length of the work has not been increased, and its original object—that of providing a small volume for the use of students and practitioners—has not been lost sight of. The book aims especially at being a practical exposition of methods of treatment and diagnosis. It is clearly written, concise, and in many ways a serviceable work.

SYPHILIS DE L'UTÉRUS ET DE SES ANNEXES.

By Dr. E. OZENNE. Paris: Masson et Cie. 1920. Pp. 226. Fr.12.

Dr. Ozenne has undoubtedly furnished his readers with more information concerning syphilis of the female genitalia than has any previous writer on this subject. The book is packed with observations, and the subject is treated with a completeness that will appeal to the syphilologist rather than to the general practitioner of medicine.

The author believes that syphilitic lesions of the cervix, the uterus, and its appendages occur with greater frequency than is generally recognised. For this reason he devotes a great deal of his work to the question of differential diagnosis. Diagnosis is, indeed, the chief difficulty, for the syphilitic nature of these lesions is by no means obvious, and it is only by a very careful consideration of all the facts of the case that a correct conclusion can be reached. Where statistics of the frequency of occurrence of the various manifestations of syphilis are available the author has furnished them. Such statistics, however, do little but emphasise the great discrepancies existing in the observations of different authorities. For instance,

the percentage of cases of primary chancre of the cervix is put by one authority at 0.53 per cent. of all cases of genital chancre, and by another (Newman) at 15 per cent. Moreover, after a careful consideration of the literature of the subject and of his own personal observations, the author has arrived at the opinion that the uterus and its appendages are much more liable to syphilitic infection than is usually supposed. Part I. of the work deals entirely with syphilis of the uterus. Part II. is devoted to syphilis of the tubes, the ovaries, and the mammary glands. The author, whilst admitting the value of the Wassermann reaction, rightly insists on the necessity of regarding this test as an adjunct rather than as the chief step in diagnosis. Great stress is laid on the value of clinical observation. The appearance of the various syphilitic lesions is accurately described and carefully contrasted with that presented by infections of a non-syphilitic nature. The omission of illustrations—doubtless for reasons of economy—is regrettable. A few plates would have been welcome, since long descriptions of pathological lesions are somewhat tedious. However, the work is a monument to the care and thoroughness with which the writer has studied his subject, and is the most complete existing work on this branch of syphilography.

SYPHILIS.

By K. K. CHATTERJI, F.R.C.S. Irel. London and Calcutta: Butterworth and Co. 1920. With numerous illustrations and coloured plates. Pp. 382. Rs.15.

THIS work by Mr. Chatterji, surgeon and dermatologist to the Campbell Hospital, Calcutta, is entirely an Indian production, being illustrated by an Indian artist and published by an Indian firm. The author has collected a large amount of information on the subject of syphilis, and evidently possesses a very extensive knowledge of European literature. The addition of his own observations in India provides a book of especial value as a record of syphilis modified by a tropical climate. The author is the originator of the margosate precipitation tests for syphilis. Sodium margosate is a derivative of margosa oil, prepared from the nim tree, and when added to an emulsion of washed red blood cells causes hæmolysis. The addition of normal serum to the mixture interferes with its hæmolytic action; moreover, the author has found that hæmolysis occurs with a greater dilution of margosate when syphilitic corpuscles are used than when the corpuscles are healthy, and a simple test is thus available. The author has also employed the margosates as therapeutic agents. The products of the nim tree have long been used in India in the treatment of skin diseases, notably syphilis and leprosy. The author has investigated the properties of margosa oil along scientific lines and has evolved a treatment based on a derivative of margosa oil from which he claims to have obtained satisfactory results. This treatment may be used in conjunction with salvarsan and mercury, and has already been discussed by Mr. Chatterji in the *Indian Journal of Medical Research*.

The pathology of syphilis is fully discussed in this volume, and the interpretation of the Wassermann reaction receives special notice. With regard to malaria, Mr. Chatterji concludes that if three weeks or more have elapsed since active manifestation of malarial infection a positive Wassermann may be regarded as evidence in favour of syphilis. Treatment occupies a very large portion of the book, and the author's conclusions are in harmony with those arrived at by the majority of European observers.

Altogether, Mr. Chatterji has produced a clearly written and well-arranged text-book on syphilis that may well become a standard work on the subject at Indian universities.

PSYCHOLOGIES.

By Sir RONALD ROSS. London: John Murray. 1920. Pp. 69. 2s. 6d. THE REVELS OF ORSERA. Same author and publisher. 1920. Pp. 393. 7s.

Sir Ronald Ross has an established reputation among modern poets, and this collection of five short dramatic

¹ Buenos Aires, vol. ii., No. 3, October, 1919.

pieces will further enhance it. In many respects these poems show a distinct advance on his "Philosophies." While there is the same wealth of imagery, a greater restraint in expression increases rather than diminishes their power. The quality of the verse is, as a rule, well maintained, but occasional weak lines occur, often with unfortunate effects.

In "The Revels of Orsera" Sir Ronald Ross shows versatility. This romance of the Middle Ages deals with the supernatural, and is based on ancient records. It contains some fine descriptive passages, and gives evidence of much historical research.

A TEXT-BOOK OF PHYSIOLOGY.

For Students and Practitioners of Medicine. By RUSSELL BURTON-OPITZ, S.M., M.D., Ph.D., Associate Professor of Physiology, Columbia University. London and Philadelphia: W. B. Saunders Company. 1920. Illustrated with 538 figures. Pp. 1185. 32s. 6d.

THIS work invades the fields of comparative physiology, physics, chemistry, and histology no farther than appears to the author absolutely necessary, for Dr. Burton-Opitz considers that the sole hope of modern medicine lies in physiology or, in a larger sense, the experimental sciences. "Since it may, therefore, be contended that 'medicine is physiology,' the student should make a conscientious effort to become thoroughly acquainted with this subject." We may say at once that the author has made a sustained and, on the whole, a successful attempt to enable the conscientious student of medicine to meet the high claim made for physiology. Diagrams and simple sketches form a feature of the book; some are original and others modifications of earlier sketches. A few of them might, we think, be improved, but the great majority of the diagrams are most helpful. It is unfortunate that such a large number of printer's errors should have crept into the spelling of authors' names.

There are one or two curious statements. "It was Cl. Bernard who first called attention to the fact that the occlusion of the duct of Wirsung produces a complete atrophy of the acini of the pancreas, but does not destroy the islets of Langerhans." (The activities of Bernard had ceased long before the discovery of the islets of Langerhans.) "Like saliva, gastric juice is secreted continuously, but only in amounts sufficient to lubricate the mucous surfaces." Amongst omissions—perhaps deliberate—are the subjects of progression in general, walking, running, and allied movements. We only point out a few shortcomings in order that greater control be exercised in the next edition. In one important respect—the introduction of certain historical data—this work is a marked improvement on most of the physiological text-books we have been called on to review recently.

The excellence and comprehensiveness of the text immeasurably outweigh its defects. The balance of the several subjects dealt with is well maintained and an adequate account of function is given in each section of a compendious, well-illustrated, and readable text-book.

ESSENTIALS OF HUMAN PHYSIOLOGY.

Fifth edition, revised and enlarged. By D. NOËL PATON, M.D., LL.D., F.R.S., Professor of Physiology, University of Glasgow. Edinburgh: W. Green and Son, Ltd. 1920. Pp. 679. 25s.

WRITTEN expressly for students of medicine and surgery by an experienced physiologist who has also had experience in teaching and practising these arts, this work has been enlarged, revised, and in part rearranged to secure a more logical sequence and greater prominence for those subjects which bear directly upon medical and surgical practice. This edition is in many respects a great improvement on its predecessors. The author need hardly apologise for allowing the names of investigators to appear frequently in his pages. On the contrary, there are a few classic names we would have gladly welcomed, notably that of Bichat in the section on tissues. The date of

each discovery would have been useful, since Mariotte's experiment, Purkinje's figures, and Dr. Beaumont's fundamental observations on Alexis St. Martin form significant landmarks. Nor need the author be concerned about omitting the terminal *e* from the names of amido-acids and other similar compounds, when on one page appear side by side katalysers and catalysers, katalytic and catalytic actions. Again, while prominence is given on p. 76 to the methods of Marchi and Weigert, we failed to find the classic term "Wallerian degeneration," although it occurs in the index. Fraunhofer (p. 167) is obviously a misprint for Fraunhofer, as is Clark's vesicular column for Clarke's (p. 118). Perhaps in referring to the theories of colour-blindness the names of Young, Helmholtz, and Hering might have been introduced, more especially as Wrightson and Helmholtz are mentioned in connexion with the theories of the action of the cochlea. These, however, are small matters.

In the section on physiology of muscle we read with pleasure the explanation of the true relationship between oxidation and muscular contraction. Contraction is not due to oxidation, but to the throwing out of sarcolactic acid—that is, to an increase of H ions, which produce changes in surface-tension with the development of "tension." Muscle in contracting thus acts not as a heat engine which liberates energy by combustion, but as a compression engine which liberates energy already stored. The subject of food is admirably expounded, especially the arguments in favour of a liberal protein intake (p. 307). On the thorny question of accessory food factors, notably fat-soluble A, Professor Paton refers to the absence of this factor "as causing not only an arrest of growth, but also a peculiar inflammation round the eyes"—presumably xerophthalmia. Of rickets he says, "the cause of the disease is still unknown." The chapters on the circulation have undergone very material improvement. A figure of the heart-lung preparation of Starling is introduced and the great physiological value of this method is expounded. The recent work on the volume, pressure, and transfusion of blood is dealt with in detail, and its bearing on the theory and treatment of shock.

We notice many additions and improvements in the treatment of the subject of respiration, and also of the complex problems that surround the secretion of urine. The information on chemical regulation of growth and function is particularly good, more especially with reference to structures with internal secretions called by the author "endocrinetes." He regards the name of hormones as unsuitable and prefers "thyreoid" to "thyroid," "neurolemma" to "neurilemma."

We feel sure that this lucid survey of the essentials of physiology and their practical application to medicine will prove an attractive and instructive exposition to the thoughtful student of medicine.

DODI VE-NECHDI (UNCLE AND NEPHEW).

By BERACHYA HANAKDAN. Edited from MSS. at Munich and Oxford, with an English translation, introduction, &c., to which is added the first English translation from the Latin of Adelard of Bath's *Quaestiones Naturales*. By HERMANN GOLLANZ, M.A., D.Litt. Oxford: Humphrey Milford. 1920. Pp. 161-160. 21s.

ONE of the characteristics of the Middle Ages was a passion for knowledge as exemplified in the rise of universities, in the wanderings of scholars not only over Europe but to the East, and in the labours of translators, the school of Gondisapor, and the literary output of men such as Michael Scott and Gerard of Cremona. English readers owe a debt of gratitude to Dr. Gollanz for having made accessible to them the two works now before us, the one a treatise by a learned French rabbi, by name Berachya, and the other a work now for the first time translated into English from the Latin, by Adelard of Bath, of which Berachya's treatise is a paraphrase or adaptation. Both are cast in the form of a dialogue between an uncle and a nephew, and are of great interest as showing the views of our mediæval forefathers on various questions in natural philosophy,

although the answers do not always elucidate the questions. For instance, Berachya's nephew asked why he could hear but not see through a wall. He was told "that sound, which is air, passes through pores which are not visible," but "the eye has power to see the wall as the light of the sun shines upon it, but it cannot see through the wall."

One question interpolated between Q. XX. and Q. XXI. of the Munich MS., which corresponds to Q. XVI. of Adelard, throws an interesting light on the process of early dissections. Adelard says: "When philosophers thought it of importance to investigate the systems of sinews and veins they fastened, no doubt, a human corpse in a river, and kept it exposed to the current until all the skin and flesh had fallen off, while the sinews and veins, which are of stouter material, were left behind. Such was the way in which the contecture was made clear to them."

Another problem discussed is, "Why the sea is salt." Berachya and Adelard both give the not very convincing reason that the sea, being much exposed to the sun's rays, becomes salt by reason of the heat. As a proof, those who live near the sea will tell you that salt is found as the residue of the water on rocks which are exposed to the sun. The saltiness of the sea was a great puzzle to our forefathers, and in Felix Fabri's delightful "Evagatorium" a long dissertation on the matter will be found.¹ He gives various opinions, but adds that the ancient philosophers erred. He quotes with approval a passage from the "Speculum Naturale," wherein the author explains that the sea water is salt because the water contracts divers qualities from the earth.

There is an interesting point of physical geography discussed in Q. VII. of the Munich MS., in 33 of the Bodleian and C. LIII. of Adelard—namely, why the inflow of the rivers does not increase the size of the ocean—and in all three places the answer is that the water gets back from the sea to the land by subterranean ways, and gets purged of its salt on the way. Adelard probably took this answer from Seneca, Quaest. Nat., but the same theory is found in Lucretius, V., 261, and VI., 608 et seq. Mr. Warde Fowler has used these passages in his usual charming manner to write a most illuminating note on Aeneid, VII., 31 to 80, concerning Virgil's idea of a great underground water system (see his "Aeneas at the Site of Rome," p. 37).

It appears from Dr. Gollancz's learned introduction to his translation of Berachya's other work, "The Ethical Treatises," that Berachya was a French Rabbi who flourished about A.D. 1160, but scholars are by no means agreed either as to the date of Berachya or as to his identity. Neubauer, for instance, says that "we must accept the existence of two Berachyas, or possibly of three." The questions both in "Uncle and Nephew" and in Adelard's treatise are not generally concerned with medical matters, but there is one question in Berachya² which puts forward the problem, "Why does a healthy man become infected when he lies with a woman with whom a diseased person had been lying, whilst the woman herself with whom this diseased one had been lying is immune from infection?" Adelard in his version limits the infection to leprosy, but it is possible that Berachya's version may refer to venereal disease properly so-called, and so be some evidence for the existence of syphilis in Europe anterior to the generally accepted date.

HANDBOOK OF DISEASES OF THE RECTUM.

Third edition. By LOUIS J. HIRSCHMAN, M.D., F.A.C.S., Professor of Proctology, Detroit College of Medicine. London: Henry Kimpton. 1920. Pp. 378. 30s.

THE author states, in the preface to the first edition, that his aim has been to produce a working handbook for the assistance of the general practitioner in the diagnosis and treatment of ano-rectal diseases. "Only those conditions which are amenable to treatment in office practice have been discussed." The author is an

enthusiast in the field of local anæsthesia, and the operative treatment of hæmorrhoids and fistula without general anæsthesia is fully described. The subject of carcinoma of the rectum does not come within the scope of this work, but the importance of early examination in all cases of hæmorrhage from the rectum is emphasised. In the present edition the text has been revised and more illustrations have been added.

Clear accounts are given of all methods of investigation used in cases of rectal disease, and special emphasis is laid on practical details which may save the patient from discomfort and from the necessity of prolonged confinement to bed. There is a good chapter dealing with the technique of local anæsthesia: the author finds $\frac{1}{2}$ per cent. solution of quinine and urea hydrochloride most generally useful. The chapter on "Constipation and Obstipation" seems rather out of place in a book of this sort and is necessarily incomplete. Most of the illustrations are good, though some seem unnecessary, as, for instance, the figure showing how to apply a lubricant to the finger.

Judged by the standard laid down by the author in his preface the book is a success.

CRISES.

By MAURICE LEVEL. Translated by ALYS EYRE MACKLIN. London: Erskine Macdonald. 1920. Pp. 239. 6s.

THESE tales of mystery and horror are translated from the French of Maurice Level, and in their original form attracted considerable attention in a well-known French newspaper. Those who read them in that form may recall the particular feeling of suspense, of pity, or of nausea which they evoked, but in their English shape it is not very probable that they will have the same appeal. The intent to thrill, soften, or sicken the reader remains obvious, but in our opinion it will generally miscarry. The little stories would have had more chance if they had reached the reader without an introduction and a prefatory note by the translator, in each of which too much is protested. Granted that M. Level employs the methods of O. Henry, this does not substantiate any right to a comparison with Edgar Allan Poe. In the French form the terseness of the work may give it an artistic claim which it lacks in the translation, but in their English garb the stories lack the sense of mystery and horror which the translator's subtitle attributes to them, and it is just that sense which makes Poe absorbing, even when he is most preposterous. Perhaps M. Level's stories "bear a closer relation to life" than Poe's, but that is quite another point; they are certainly not "more concentrated in their horror." They are, as a matter of fact, machine-made stories of the fat-boy order, and suffer, as collections of stories written on the same recipe must always suffer, from the monotonous effect produced. The first story is the best in the book.

DISEASES OF THE CHEST AND THE PRINCIPLES OF PHYSICAL DIAGNOSIS.

Second edition, revised. By GEORGE WILLIAM NORRIS, A.B., M.D., and HENRY R. M. LANDIS, A.B., M.D., Assistant Professors of Medicine in the University of Pennsylvania. With a chapter on the Electrocardiograph in Heart Disease, by EDWARD B. KRUMBHAAR, Ph.D., M.D., Assistant Professor of Research Medicine in the University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. 1920. Pp. 844. 35s.

IT is less than two years since the publication of the first edition of Professor Norris and Professor Landis's book. Certain articles in the present issue have been recast, and there have been added descriptions of several conditions previously omitted. These include such subjects as influenza, streptococcal empyema, spirochaetal bronchitis, calcification of the lungs, chronic inflammatory conditions of the lungs of uncertain aetiology, and pneumopericardium. The book does not concern itself with treatment; its chief aim is to serve as a guide to the physical diagnosis of diseases of the heart and

¹ Vol. i., Ed. Hasler, 1843.

² Munich C.J. xlii., Bodleian MS. 26, Adelard xlii.

lungs. The authors rightly insist that it is only through a comprehension of the laws governing the production and transmission of sound that the results of percussion and auscultation can be intelligently interpreted, and they devote the first 260 pages to the examination of the lungs and circulatory system, the subject of diagnostic acoustics being treated at greater length than is usual in books of this character. In the main this section of the work is in accordance with scientific principles and leaves little to be desired. Another feature calling for comment is the lavish provision of photographs of frozen sections from the cadaver previously hardened in formalin, so that the anatomical relations of the organs are preserved as in life.

In the later portions of the book dealing with morbid conditions of the heart and lungs no less than 15 clinical varieties of pneumonia receive notice, and this is a fair example of the very thorough manner in which the authors have carried out their task. They appear to take the view that influenza is primarily attributable to Pfeiffer's bacillus, but that in a very large number of cases the bacillus opens the door to other organisms, such as streptococci, pneumococci, staphylococci, and Friedländer's bacilli, and that these secondary infections are largely responsible, not merely for various complications which may arise in the course of a case, but even for the protean forms which this particular fever may assume. The book is beautifully and profusely illustrated, and the new edition is certain of a favourable reception.

WAR AGAINST TROPICAL DISEASE.

By ANDREW BALFOUR, C.B., C.M.G., M.D., &c.
London: Baillière, Tindall, and Cox. 1920. Pp. 220.
12s. 6d.

UNDER this title are collected in one volume a number of lectures, or sermons as the author prefers to call them, delivered on various occasions on the common text of the supreme importance of hygiene in waging war against tropical disease, and published under the auspices of the Wellcome Bureau of Scientific Research.

In addressing different audiences Dr. Balfour treats his subject from many points of view, but always with an erudition and felicity of expression which do the fullest justice to the intrinsic interest of his theme. Interwoven with the subject-matter is a wealth of anecdote and apt quotation, and the result is a volume of absorbing interest, which the reader is not likely to lay aside till he has perused it to the last word. In the lecture on preventive inoculation against typhoid and cholera, originally delivered at a meeting of the Research Defence Society, nothing is lost through the presentation of the subject in non-technical language, and the essential facts of immunity are indicated in a manner which is intelligible to those who do not possess a strictly scientific training. Included in the series are the Chadwick lectures for 1919, in which the author deals with the problem of hygiene in Egypt, and comments on the important findings of the Commission, of which he was the chairman, appointed to inquire into the organisation and work of the public health department of Egypt. These lectures were published in full in THE LANCET last September. The only serious defect in a book teeming with information of a practical kind is the absence of an index; this is not compensated for by the very full table of contents.

JOURNALS.

Tubercle. A Monthly Journal Devoted to All Aspects of Tuberculosis. Vol. I., No. 10. July, 1920.—Dr. W. C. Rivers. leads off with a short study of four clinical phenomena of tuberculosis—viz., trauma, muscular signs, vicissitude, and recidivism—treating them with clinical insight though he is mistaken in saying that "until lately practically no consumptive recovered, so that practically none could relapse." There are many historic cases of recovered tubercle; Goethe and Ruskin were doubtless such, and recidivism is perhaps as old as the disease. Dr. Rivers points out the high diagnostic value of trapezius atrophy and shoulder drop in pulmonary tubercle, and concludes by suggesting that the four phenomena above referred to indicate a high degree of natural immunity, and would thus probably be rare in lunatics and in negroes and Polynesians.

New Inventions.

A SIMPLE FORM OF RHYTHMIC INTERRUPTER.

IN treatment of paralysis following poliomyelitis, &c., by means of arm and leg baths it has frequently been shown that a rhythmic interruption of the current produces the best results. This is usually obtained by a motor-driven contrivance, which is bulky and expensive. The apparatus described below can be made for a few pence, and I have found it perfectly automatic and reliable. In construction it is somewhat similar to that described by Dr. Norman Aldridge in THE LANCET of Jan. 8th, 1910. The syphon arrangement of the present form was found to work more evenly.

The apparatus consists of A, a glass tube 6 in. long, $\frac{5}{8}$ in. bore, open at both ends, and connected by means of rubber cork B with glass tube C, which is bent in the shape shown and has $\frac{1}{2}$ in. bore. At the end of C is fitted a rubber tube D, of convenient length to discharge into sink or pail. Two electrodes, EE', are then cut from sheet copper 3 in. long, $\frac{1}{2}$ in.

FIG. 1.

FIG. 2.

FIG. 3.

wide at top, and shaped as shown in Fig. 2. Wires FF' are soldered to these and the electrodes are moulded to fit the tube A, and kept in position by a short length of rubber tubing, C, fixed between them (Fig. 3). The whole apparatus is mounted on a board. The leads FF' are put in the circuit of the current to the baths, whether this be continuous, sinusoidal, or faradic. The apparatus is then suspended from a water tap and the flow of water adjusted. It will be found that the water will rise in the tube A until it reaches the level of the top of tube C, and will then syphon automatically. As it rises more and more current will flow between the electrodes until a maximum is reached and then it will wane to zero again.

A suitable periodicity is about 15 per minute, and this rate is obtained in the apparatus described. The rate depends on the ratio of the bore of tubes A and C, and bearing this in mind a quicker or slower periodicity can easily be obtained. Debatat, experimenting on rabbits, used a periodicity of 30 per minute and showed a 40 per cent. gain in weight with faradic current and an 18 per cent. gain with galvanic current. He stimulated the hamstring muscles of one side four minutes daily for 20 days and obtained these results by comparing with the opposite side.¹ H. Bordier made similar experiments on muscles of a healthy human being and obtained similar results.²

It is important to prevent stretching of the paralysed muscles by the opposing set, and to obviate this light splints can be arranged during the bath treatment.

Sutton, Surrey.

THE APPOINTMENT OF WOMEN MAGISTRATES.—Early in the week a list was issued by the Lord Chancellor containing the names of the women to sit on the judicial bench in England, Wales, and Scotland. The names were submitted to him by the Women's Central Advisory Committee appointed for the purpose. Amongst the names, which are not intended to be complete, appear those of Dr. Ethel Bentham, Dr. Janet Lane-Clayton (dean of the Department of Household and Social Science in King's College for Women), and Dr. Mary Scharlieb.

THE LANCET.

LONDON: SATURDAY, JULY 24, 1920.

The Organisation of Medical Service.

THE Health Services Vote, that is, the vote for the salaries and expenses of the Ministry of Health, including the grants and expenses with regard to Housing, the grants to Local Authorities, and those to meet the demands under the National Insurance Health Acts, was taken in Committee in the House of Commons at the end of last week. In our Parliamentary report there will be found a résumé of the important speech in which Dr. ADDISON told the House and the country something of the size of the problems which his Department in the first year of its existence had had to deal with, and something of the way in which the responsibilities had been met. The things to be done and the ways to do them were alike so multifarious that it would have been as useless as impossible for the Minister of Health to do more than give outlines, but every word that was said by Dr. ADDISON revealed that necessity for the organisation of the health services of this country which was the origin of the Ministry of Health, while his description of the courses taken to meet the various difficulties and the commencements made to deal with them showed insight and foresight. During the first year of its existence the amalgamation of the work of the Health Insurance Department with the Registrar-General's Department and with the work of the Board of Education, both in regard to School Medical Service and the care of prospective mothers, has proceeded steadily; the duties of the Home Office under the Children Act are being brought into line with the activities to which they have a natural affinity; while definite steps are being taken to deal with the position of lunacy, the incipient stages of which have hitherto been neglected by preventive medicine.

Such is Dr. ADDISON'S message to the country, but in the meantime developments have taken place indicating with some particularity the part to be played by the practitioner of medicine in this huge programme. In announcing last week the appointment by the Ministry of Health of a service of outdoor medical officers for whole-time duty we suggested that those officers, who represent a distinct advance in the organisation of panel service, would also play their part in the general organisation of the medical service of the country in its initial stages. How this will come about exactly in any given place depends upon local circumstances to a great extent, and it is previous to dwell upon this side of the matter while many of the detailed activities promised under the appointment of outdoor medical

officers have still to be put in going order. At the present moment the great necessity for medical men is to take an all-round view of what is being done by the Ministry of Health for the national organisation of medical service. How is the general plan of the Ministry evolving is the question now, and the subsequent questions will be—How does any particular action or promise of the Ministry fit in with that plan? A profession like that of medicine is not expected by anyone to follow blindly an arbitrary leadership—the whole spirit of Dr. ADDISON'S administration shows that he expects nothing of the sort; but the task before his department and before the medical profession, upon whose shoulders the future work will mainly lie, is so far reaching, and so intimately bound up with the social life of the people with its multifarious interests, that it cannot be easy for any of us to keep the central ideas prominent. The Interim Report of the Consultative Council of Medical and Allied Services for England—it will be more convenient if for the future this document is alluded to as the Dawson Report—has now been under the consideration of all sections of the medical profession, of the British Medical Association, and of the public for some weeks, while here and there points in it have been the subject of Parliamentary comment. The ideal nature of many of the proposals is confessed, and the expense of the institution of any such scheme in entirety would be colossal, so that no one, least of all the Council itself, expects legislative realisation of the recommendations *en bloc* and at once. But all the public notice which the Report has received confirms one impression. It is this. That it is considered, alike by the medical profession individually and through the British Medical Association, that the erection of Primary Health Centres is not only a pivotal part of the projected scheme, but a necessary development of the modern reading of preventive medicine in the larger sense—not the preventive medicine called hygiene, but that preventive medicine which forms the therapeutics of the future and which aims at arresting disease at its inception. Of the way in which the Primary Health Centre may work, practical illustration has been given both in the Dawson Report and in the recent discussion thereon at Bristol, when Dr. MIDDLETON MARTIN, the medical officer of health of Gloucestershire, described what had been proposed in his own county. We may take it for granted that something analogous to the organisation which he explained, and whose features may have been familiar to some of his audience, is beginning to work in Gloucestershire and will be applied elsewhere, assuming that the necessary expenses can be met. For purposes of clearness the statement must be repeated that Primary Health Centres cannot all be of the same pattern and probably will not be able to discharge the same public and professional duties. But they should all have this in common—whether they be newly constituted centres, or developments of existing cottage hospitals, or intimately allied with secondary or superior health centres as developments of the out-patient departments of voluntary hospitals—they will all be centres at which the professional and scientific activities of the general practitioners of the neighbourhood can be concentrated and from which they can be diffused.

The first stage, then, in the organisation of medical service under the Ministry of Health promises to

be the establishment of Primary Health Centres, with due regard to local circumstances; and we see at once that, as these centres are to be based upon Secondary Health Centres, in other words upon the great voluntary hospitals, the voluntary principle will be supported in the main, however much local circumstances may here also play a part in dictating the measure of State or municipal assistance required. But the general practitioners who will staff and conduct the Primary Health Centres will in a great proportion of cases be associated with panel practice, the practice in which the new outdoor medical officers will play an important part in the future. Thus a medical service coördinated in all its forms should arise, the general practitioners of the country being the foundation upon which the fabric stands. Their energies, private or public, and whether grouped at their centres or diffused in part-time appointments of a public nature, will be brought into touch alike with all that the great voluntary hospital stands for in knowledge, research, and training, and with the official administration of the Ministry of Health.

Plastic Surgery of the Face.

SUCCESSFUL demonstrations at the Cambridge meeting of the British Medical Association no doubt brought home to a wide circle the progress made during the last few years in the plastic surgery of the face. The awful disfigurements produced by war wounds of the face must have seemed to some of the sufferers worse than death itself, and the appeal of their mental sufferings to the surgeons confronted with the task of alleviating their condition was assuredly very great indeed. These demonstrations were given by Mr. P. P. COLE and Mr. H. D. GILLIES, whose names have for some time been associated with the advances that have been made in the plastic surgery of the face, and now the latter has made public in a large and fully illustrated volume¹ the results which he has obtained following on the intensive work at the Queen's Hospital, Sidcup. This hospital was staffed by officers picked with great insight from institutions whose loss became Sidcup's gain. Our columns have included at various times the work of Mr. KELSEY FRY, Mr. J. L. AYMARD, Mr. G. SECCOMBE HETT, Mr. H. P. PICKERILL, Mr. GILBERT CHUBB, and others. Hence, while special departments at other hospitals were earlier in the field, notably that of the Eastern Command at Croydon under Sir FRANK COLYER's direction, Sidcup has naturally obtained the larger measure of public recognition. No doubt all the medical staff at Sidcup felt very strongly the emotional appeal to which we have alluded, and the wards, we know, afforded extraordinary opportunities for observations on the psychology of the wounded man; but it is clear that they have also been stimulated by the pride of the craftsman, and it is, naturally, this side of their work which is described in the volume before us. Mr. GILLIES modestly points out that nearly all the methods employed have been in use for many years, some of them for six centuries or more, but ancient lineage does not detract from modern prowess. It is quite evident that for the develop-

ments of technique initiated at Sidcup inventive courage and an almost superhuman patience were needed, and even these qualities would not have led to success unless coupled with an unusual dexterity and ingenious and creative minds. Many of Mr. GILLIES's operations were so boldly conceived that it might well have been forgiven him had he compromised with the misgivings he must occasionally have felt in carrying them out. But scientific conviction did not fail; rather it found support in hope and imagination, which carried the various operators over periods of failure and depression and allowed them to call upon their patients for trust.

In the final result it is not only those suffering from the immediate effects of the war that have benefited, but also those who have endured the ravages of disfiguring disease or accidents. The work first devised and done at Sidcup has passed into civilian practice, and some strikingly successful cases of plastic operations for conditions such as lupus and epithelioma of the face were shown at the Cambridge meeting. It is now possible to enunciate certain principles which must affect the course of surgery in the future. Never before has "cosmetic" work been done in such bulk or subjected to such searching criticism, but now it can be claimed that the science of plastic surgery is being built up on solid foundations, with much of the evidence fully recorded. The first great principle that is laid down is the paramount importance of restoring function; good cosmetic results will follow if this principle be never forgotten. The fashioning of a new nose failed until function came to be the prime object; the elaborate operation finally devised has in many cases been entirely successful both functionally and cosmetically. The same principle stimulated the elaboration and ultimate success of the process of epithelial inlay, of bone-grafting in the mandible, of cartilage-grafting for various purposes, and of other operations on the orbit, eyelids, and lips, ingenious procedures due to many minds and finding many shapes.

In fact, the rapid development of plastic surgery has been a remarkable vindication of the value of "team work," the team consisting of surgeon, dentist, and artist. Mr. GILLIES was fortunate in having the help of Mr. KELSEY FRY as dental surgeon, and of Professor HENRY TONKS, an anatomist and surgeon who long before the war had deserted medicine for art, but who here found an opportunity for reconciling his double range of great accomplishment. Mr. GILLIES in the preparation of his book has fully recognised the value of graphic record in this branch of surgery. He is throughout sparing of words, but prodigal of pictures and diagrams, so that the work easily achieves lucidity. And this is well, for the general application of the same methods to the conditions met with in civil practice is of immediate importance, although the time may hardly yet be ripe for a department of plastic surgery at a general hospital. The defacements of heredity, disease, and accident are insignificant compared with the results of high explosives. The world of surgery may feel encouraged by the results obtained by plastic surgery in the war, but Mr. GILLIES's book should go beyond the circle of his professional brethren and be distributed as a deterrent to the politicians of every country, for the things thus put before their eyes might well be a potent factor in promoting peace among the nations.

¹ The Plastic Surgery of the Face. Based on selected cases of war injuries of the face, including burns. By H. D. Gillies, C.B.E., F.R.C.S., Major, R.A.M.C. London: Henry Frowde, Hodder and Stoughton. 1920. Pp. 408. 3 guineas.

Drugs and their Active Principles.

WHEN we consider the many drugs in present use that owe their properties to unknown constituents we must admit that an almost eternal task lies ahead. Senna tea has been the standby of a thousand years of grandmothers; squill and hemp were used as medicines 1500 years ago; gentian was commonly employed in the middle ages—and yet to-day we do not know what gives their virtues to any of these drugs. To go back to even more remote times, there is rhubarb, whose qualities were known 5000 years ago, and yet our knowledge of its active principles is very incomplete. Not long ago there was a sanguine school which believed we were on the threshold of an era in which old methods would be discarded, and that instead of using preparations of raw drugs we should isolate and prescribe the principles which give these drugs their properties. We are almost as far away from this as ever. It is true that research workers have discovered most of the secrets of a considerable list of important drugs, including belladonna, cinchona, ipecacuanha, opium, aconite, and a number of others; but although atropine, quinine, emetine, morphine, and aconitine are readily available in a pure state, the tinctures and other preparations of the new drugs from which these active principles have been isolated are still in daily use. And rightly so.

These reflections result from a perusal of the informative and suggestive address on Progress in Science and Pharmacy delivered by Mr. C. A. HILL, the President of the British Pharmaceutical Conference, at the annual meeting of the Conference held at Liverpool this week. That tincture of nux vomica continues to be prescribed instead of strychnine is not merely because of habit and tradition, but because of the difference between the action of the tincture and the pure alkaloid. This difference, says Mr. HILL, is mainly to be attributed to the effect of the extractive matter in retarding the rate of absorption and in retaining the alkaloid in solution even in the presence of alkaline media which would precipitate pure strychnine. Let us take opium and its alkaloids; it is common knowledge that the replacement of the crude drug by morphine and codeine is far from complete; the reason in this instance is that opium contains more than 20 different alkaloids, possessing varied physiological properties, in addition to several organic acids and other matter. The presence of these substances in opium preparations serves to delay and sustain their action, and since sustained action is often what is required in a narcotic drug it is clear why galenical preparations of opium retain their vogue. Obviously, there are cases where the more rapid action of strychnine or morphine render these alkaloids more suitable than preparations of nux vomica and opium, but there is an abundance of evidence in favour of retaining both classes of medicament. Until quite recently there seemed little doubt that preparations of cinchona bark had been almost superseded by quinine, but the work of Major H. W. ACTON, to certain results of which much importance is attached, indicates that while quinine is useful in the treatment of malignant tertian malaria, it is of small value in eradicating benign malaria; on the other hand, the total alkaloid of cinchona is found by Major ACTON to be effective for the latter purpose. These few examples serve to show that when we have

isolated the active principles of drugs our work is not completed. However much we may wrest from her, Nature still holds back some secrets. It may be the presence of other active principles and of apparently inert matter that causes the difference in action, or there may be yet undiscovered and more mysterious causes; for, in Mr. HILL's phrase, as our knowledge of such bodies as vitamins, enzymes, and hormones advances, so our respect for the natural sources of such bodies increases.

All this suggests possibilities of danger in over-refinement. Search how we may, some drugs have constituents, minute in quantity but of the highest degree of importance, which we have not yet been able to discover. We can only go on working with the prospect that when our work is done we shall find that Nature is still the superior artificer. In the course of his argument the President of the Conference used as an analogy, and we think very aptly, the causation of beri-beri; as is now well known, this disease is caused by the refinements of rice-milling, brought about by the introduction of machinery. The absence of something—belonging to a class now widely known as vitamins—in the rice, removed in the process of steam polishing, was the cause of the trouble. Scurvy, which used to be the scourge of the navy, yields readily to a diet of potatoes, cabbages, and most fresh fruits; sailors in the old days died of scurvy because they were deprived of the vitamins contained in this diet. We think it is permissible to apply both these analogies to the case of drugs. Refine by all means, but let us remember that there may be more danger in our process than in no refinement at all. It is not because we are slaves of habit that galenical preparations of whole drugs are still in some cases preferred to the active principles, but rather because clinical experience, now endorsed by the laboratory, has demonstrated that the crude drug may have advantages over the refined one. Herein is clinical wisdom justified of her children.

Annotations.

"Ne quid nimis."

THE REALM OF NEUROLOGY AND PSYCHOPATHOLOGY.

THE two lectures which appear in full at the front of our present issue are an indication of the amount of keen thought that is being devoted to the subject of nerve symptoms, using this term as Sir Thomas Horder uses it in the widest possible sense. Dr. A. F. Hurst, in his first Croonian lecture, limits himself strictly to a consideration of changes in cutaneous sensation, but finds even within this limit material for an almost new conception of functional nervous disorder. Sir Thomas Horder sets out to help the practitioner faced with a patient taken suddenly ill with a symptom-complex containing elements of a nervous kind. Both tread on ground, broken, indeed, by the neurologist, but on which the practitioner must follow. The first number has recently appeared of a new quarterly journal devoted to neurology and psychopathology, published under the direction of an editorial committee of three in each of the two compartments: Dr. S. A. K. Wilson, Dr. T. Graham Brown, and Dr. R. M. Stewart for neurology; Dr. Bernard Hart, Dr. Henry Devine, and Dr. Maurice Nicoll for psychopathology; with Dr. Carey F. Coombs as editorial secretary, the journal being

published¹ in Bristol. Two brief and pointed unsigned articles show what is the editorial mind in embarking on the troubled waters of special journalism. The first pictures the realm of neurology invaded on all sides by the doughty protagonists of endocrinology, ophthalmology, psychotherapy, embryology, biometry, eugenics, and many another. Neurasthenia might, indeed, it is humorously suggested, be rescued as the remaining fragment of the neurologist's kingdom were he not "assured by the endocrinologist that it is a disease of the ductless glands, by the alienist that it is a form of mental disorder, by the cardiologist that it is a functional cardiac disturbance, and by the Freudian that it is a sort of nosological Mrs. Harris." The truth is rather that the neurologist of to-day pursues the study of either psychical or physical side, or both, and has succeeded to an empire built up by the scientific and clinical research of many groups and fellowships of workers. The second editorial article carries this thought further and suggests that the most fruitful line of advance at the present time is that of biological reaction, mental and nervous disorders not being distinguished as disease entities, but rather as different types of reaction to environment shown by a psychophysical organism. With these aims we are in cordial agreement, and we believe that a journal in which they are successfully applied will appeal to a very large number of the growing generation of medical students and graduates who have not been brought up to accept without question the dualistic conception of mind and matter, and who feel more at home in the standpoint of the behaviorist, as lately set forth in Professor John B. Watson's admirable book,² which is persuasive by reason of being easy to understand. The same cannot be said for the new psychopathology. As Dr. Geikie Cobb very fairly complains in a letter in our correspondence columns, the nomenclature now employed by psychopathologists is nothing short of bewildering to the practitioner engaged in general work, as much in regard to the terms describing the disorders as the mechanism producing them. This obscurity inevitably tends to produce a separate cult instead of the much needed vivifying effect on medical practice in general. The new journal is not quite free from complicity in this evil, for it allows neurologist to abstract neurologist, and psychopathologist to abstract psychopathologist, which perpetuates a vicious circle. Better, surely, might be a trial of the physiologist's crossed-heads experiment. Abstruse work on psychopathology, reaching the practitioner through the medium of the trained neurologist, would not elude him as it does at present. The interpretation of neurology in the light of psychopathology is no less desirable. Is it too much to hope that in this way we might get something like a satisfying presentation of clinical psychology.

THE CASE FOR CASEIN.

THE employment of "protein milk" in infant feeding is reported to be attended with such encouraging results as are likely to upset former theories as to the inferiority of cow's milk compared with mother's milk for the purpose. It was generally held that the excess of casein in cow's milk as compared with human milk embarrassed the child's powers of assimilation, coupled with the strong saline content of the serum or whey. In our own experience in laboratory examination, cow's milk has seldom been modified to an extent which brought the casein, to say nothing of the mineral constituents, down to the level of the natural pabulum of the child. The use of protein milk in the treatment of infantile gastro-enteritis was introduced by Finkelstein in 1910. He suggested an interesting modification of cow's milk, replacing a litre of milk by the clot of casein, produced presumably by the use of rennet, and mixing it thoroughly with half a litre of water to which is added half a litre of butter milk. A suitable

addition of carbohydrate is made (3 to 5 per cent.), consisting of a mixture of maltose and dextrin (Soxhlet sugar). It is obvious that by this procedure the proportion of casein remains the same, but the mineral contents of the cow's milk are halved. The notable decrease in the salts of cow's milk, in milk prepared on these lines, diminishes the saline elements conducive to intestinal intoxication. Further, casein so presented, far from causing foetor of stools, is an excellent antifermentative, and proves easily absorbable in the infantile alimentary tract. It increases, it is stated, the alkalinity of the intestinal juice and prevents auto-intoxication. These observations are based on a paper appearing in the July number of the *International Journal of Public Health*, published by the League of Red Cross Societies, Geneva, by Ad. D'Espine, professor of pathology and diseases of children in the university of that city. Whilst admitting that in the treatment of the gastro-enteritis of infants protein milk is inferior to mother's milk and not to be recommended as a diet for a healthy baby, yet the author concludes that it proves a food of the greatest service in the treatment of the dyspepsias of infancy, hastening recovery and cure. Protein milk, however, must clearly be wanting in accessory food factors unless the casein clot carries with it the fat.

SACRO-ILIAC SCIATICA.

IN the *Revue de Médecine* Professor J. A. Barré, of Strasburg, and Major P. L. Duprey have described a form of sciatica which has received little attention, and which they term "sacro-iliac sciatica"—sciatica due to disease of the sacro-iliac joint. The sacro-iliac joint is in contact with the lumbo-sacral trunk and its large branch, the superior gluteal nerve. Hence peri-arthritis may affect these nerves. In sacro-iliac sciatica there are two elements, articular and nervous, of which one generally preponderates. The mode of onset varies. A sprain of the joint may occur as the result of torsion of the body in playing tennis. The patient is seized with pain in the upper and inner part of the buttock, drops his racket, and puts his hand on the spot. He walks with difficulty, but on resting the symptoms pass off. The same may occur in lifting an object when in a bad position. A pain which is more tolerable and more diffuse follows. After a time, it may be some weeks, the symptoms of sciatica appear. Another mode of onset is by a febrile attack with arthralgias which become localised in the back and in one or both lower limbs. On turning the patient on his side the region of the sacro-iliac joint is found to be swollen and very tender, while the spine is almost painless, except in the space between the last lumbar vertebra and the posterior border of the ileum. This is a case of rheumatic sacro-iliac arthritis. The patient carefully avoids movements of the pelvis or hip, and examination does not allow more to be ascertained than that the posterior part of the thigh is painful. But in a few days the pain almost leaves the sacro-iliac joint and descends. It is most manifest in the thigh and may extend to the foot. In another form patients who have never had a febrile attack suffer from pains in the buttock and have difficulty in walking. They are generally considered to be suffering from chronic sciatica, but, as its signs may be absent for a long time, malingering may be suspected. Careful examination reveals a series of signs of which several have been overlooked—sacro-iliac pain, atrophy of the muscles of the buttock, rigidity of the lumbar spine, contracture of the muscles of the joint, limping, and ascension of the iliac crest. Radiography reveals an ill-marked articular line, decalcification of the ends of the bones, and foci of osteitis. It is a case of sacro-iliac arthritis, generally tuberculous. In sacro-iliac disease pain may be produced in the joint by different manoeuvres—by getting the patient to sit down brusquely, to fall, so to speak, on his ischial tuberosities, by pressing the two iliac crests together, or by pressing on the head or shoulders, which tends to press the sacrum like a wedge between the two iliac bones. Often the patient sits only on the buttock of the sound side. Pressure on the whole buttock on the diseased side is painful not merely over the sciatic

² Psychology from the Standpoint of a Behaviorist. J. B. Lippincott, Co. 1919.

nerve, but over the course of the superior gluteal nerve. Neuralgic sciatica is felt specially in the upper part of the thigh and rarely extends below the knee, though in the paroxysms the pain may radiate to the foot. In this sciatic stage the articular pain has diminished or disappeared. There are physical signs in the form of dorso-lumbar scoliosis with the concavity towards the affected side, lowering of the shoulder, and diminution of the costo-iliac space. Owing to hypotonia of the muscles the gluteo-femoral fold is lowered and the furrow between the buttocks is deviated below towards the affected side. In ordinary sciatica the patient suffers more in the calf and foot, and pressure on the course of the nerve produces acute pain; and it is in the leg and foot that atrophy is earliest. In sacro-iliac sciatica atrophy is earliest in the buttock. According to Professor Barré and Major Duprey, sciatica with a painful sacro-iliac point is due to sacro-iliac disease. The treatment consists in using the ordinary anodynes for the pain (aspirin, aconite, gelsemium), hot air, liniments, and massage. In the rheumatic form salicylate is given. The joint is immobilised by applying a binder of inelastic material extending from the iliac crests to the trochanters.

LIMBLESS MONSTERS.

THE case reported last week by Dr. Cawas Homi is an example of a well-known, though uncommon, type of deformity which has always excited interest among medical men and in the laity. As is the case with so many monstrosities, the condition is usually referred by the mother to some strong pre-natal impression. The impossibility of explaining the *modus operandi* of a maternal impression, or of imagining it in action, is not of much logical weight in considering the matter, but it has so happened that the deformity in most cases must have been produced at a stage in normal development antedating by a greater or less time the occurrence of the impression. This, in conjunction with modern views as to the percentage of all conceptions which become monstrous to some degree, is enough to afford an explanation apart from the impression; but we still lack reliable data concerning the percentage of pregnant women who suffer from ante-natal impressions. The frequent occurrence of other common malformations with the ectomelic state does not agree with the influence of maternal impression. Dr. Homi's case is not open to the objection that the suggested maternal impression came too late in the gestation-period to have its influence, but is an ectomelic case differing in no other way from the rest; it is to be regretted that no expert dissection of the limbs was possible.

IMPROVEMENTS IN THE INDIAN MEDICAL SERVICE.

IN our last week's report of proceedings in Parliament¹ we gave in detail the new rates of pay and other improvements in the conditions of the Indian Medical Service, as stated by Mr. Montagu in the House of Commons on July 12th. They may be summarised, as regards the chief points, as follows: Formerly, a medical officer on joining, with the rank of lieutenant, drew Rs.550 per mensem until promoted to captain, when he received Rs.700. According to the new scale he commences with Rs.650, and after three years' service becomes captain with Rs.800. Formerly, while in the rank of captain, he obtained successive increments of pay up to Rs.750, Rs.800, and Rs.900 after 5, 7, and 10 years respectively; now he draws Rs.800 during his first three years as captain, Rs.950 in his next three, and Rs.1050 in his tenth, eleventh, and twelfth years, reaching Rs.1200 on promotion to major after 12 years, instead of Rs.1000 as formerly. After 15 years he draws Rs.1350, and after 18 years Rs.1500, as compared with Rs.1150 formerly from the completion of his fifteenth to completion of twentieth year, or promotion to lieutenant-colonel. After 20 years' service he now draws Rs.1750 (compared with Rs.1550 previously), after 23 years Rs.1850, and after 25 years Rs.1950, and if on the selected list Rs.2100. Charge

allowance, varying from Rs.120 to Rs.240, is also issued to officers in command of all except the smallest hospitals, and in the larger hospitals of the first and second class the second in command also draws an allowance of Rs.120 and Rs.90 respectively. Concessions are to be granted with regard to pensions, passages, and leave; and as regards the status of the Director-General and Surgeons-General, these officers are to have the right of direct access to the Viceroy or Governor, as the case may be, and of access to documents the same as possessed by the Secretary to the Government. The improvements indicated, both pecuniary and in regard to official status, appear to have a substantial value and to evince a genuine desire on the part of the Indian Government to meet the legitimate claims of the officers in the Medical Service.

THE VALE OF SIDDEM.

WITH perfect good faith, doubtless, some of our American friends have commented on the evidences of degradation and immorality which they have found when visiting the cities of Europe, and have congratulated themselves on the superiority in these respects of "God's own country." This complacency will receive a shock if they will devote themselves to the perusal of a book which has just reached us from the United States.¹ Its title seems to foreshadow something of poetry, and its format lends support to the anticipation, for the work is one of those neat and modest little volumes with which diffident minor poets are wont to deprecate their indulgence of the *cacoethes scribendi*. There is, indeed, "poetry" in it, for it starts off with the following rhyme:—

"All the wicked people
In the Vale of Siddem
Thought of things they shouldn't do,
And then they went and did 'em."

Thus are we prepared to face a grim and depressing story. In a valley through which flows one of the tributaries of the Mississippi river, in the State of Minnesota, there dwells a community known locally as "timber rats" and "bark eaters." Its members are the fruit of regular and irregular unions between several families all hopelessly antisocial. Thus we have the Yaks, from one daughter of whose house there were derived 79 persons, of whom 10 were insane, 15 feeble-minded, and 8 epileptic; the first generation including 14 children, of whom 9 were insane and 1 was feeble-minded. Another Yak married into the Bart family. His wife, herself insane, was one of five brothers and sisters, three of whom were insane. These five had among them 14 descendants, 7 of them being either feeble-minded or insane. Delilah of the Cam family was one of 9 children, of whom 7 were feeble-minded. She married into the Glade family, whose record is much the same, and had 11 children, of whom 2 died young, while of the remainder 1 only was of normal mentality. "Muskrat Charlie" married a feeble-minded woman and had 11 children, of whom 3 died shortly after birth and the rest were feeble-minded. So the story goes on. Summed up, of 1619 dwellers in the Vale of Siddem 892 furnished no sufficient information for any report, 114 died in infancy or early life, and of the rest there were only 156 who could be regarded as normal; 199 were feeble-minded, 34 insane, 125 sexually immoral, and 134 alcoholic—i.e., individuals who drank "habitually and to excess." Of the feeble-minded only about 5 per cent. have been reached by the available agencies for care and control. The outlook could hardly be less satisfactory. As the authors themselves put it: "From the standpoint of eugenic consideration the existence of such communities as the Vale of Siddem makes our present attempts to care for the feeble-minded quite idle. The sources of the apparently inexhaustible supply of mental defectives remain unaffected. It is like trying to stamp out malaria or yellow fever in the neighbourhood of a mosquito-breeding swamp."

POST-GRADUATE MEDICAL STUDY IN LONDON.

WE have received from the Deans of the Post-Graduate College, West London Hospital (Dr. Arthur Saunders and Mr. Bishop Harman), the prospectus of the Special Vacation Course arranged for the month of August. There will be daily demonstrations and lectures; the subject of each of these is stated in the time-table, and deals with some aspect of medical practice which must be of interest to every practitioner. The full clinical work of the hospital will be available for medical practitioners in the medical, surgical, and special departments. Arrangements have been entered into between the College and certain special hospitals to give facilities to post-graduates in these hospitals—e.g., Brompton has entered into this alliance, to the evident advantage of practitioners who wish to take out a general course and yet desire to do more work on tuberculosis than a general hospital can provide.

DR. COOLIDGE'S SERVICE TO RADIOLOGY.

Dr. W. D. Coolidge delivered an address before the members of the Röntgen Society on July 15th in the new Chemical Theatre of University College. There was a large and representative audience, including a number of the leading scientists and medical men interested in radiology. Dr. Coolidge in his opening remarks paid a striking tribute to the pioneer work done in Britain on the physics of X rays and allied subjects, referring particularly to the work of the late Sir William Crookes, Rutherford, the Braggs, Wilson, Richardson, and others. The lecturer gave an interesting description of the research laboratories of the General Electric Company at Schenectady. From his detailed description of these laboratories it is clear that the equipment of such centres for the practical application of the discoveries of pure science to commerce leaves very little to be desired. He went on with a most interesting description of the steps in the production of ductile tungsten, illustrating the procedure by a number of lantern slides. He described many interesting technical details necessary for the production of a form of tungsten suitable for, amongst other things, the essential parts of an X ray bulb. The most striking feature of this part of the address was the evidence of the infinite care and attention to detail which are required in the handling of this most difficult of metals. Although the lecturer modestly made no reference to the fact, it is well known that the research work in the elucidation of this problem has been carried out by Dr. Coolidge himself. The production of ductile tungsten paved the way for a great advance in the design and construction of the X ray tube. Up to the advent of tungsten in working quantities platinum was used for the target of the X ray tube. Tungsten possesses several advantages over platinum, and soon it displaced to a large extent the latter metal. The very clear description of the methods by which a tungsten button was fixed upon the copper target of the tube enabled the lecturer's hearers to grasp to some extent the skill requisite for the manufacture of a modern X ray bulb. This part of the lecture dealt with the physical and chemical properties which complicate the making of a gas tube. To the radiologist this was most interesting, and helped to explain many of the vagaries of the X ray tube when in action.

The lecturer next proceeded to deal with the further developments and the experimental work which culminated in the production of the tube which bears his name. Needless to say, the metal tungsten enters largely into its construction, the anode and part of the cathode being made of that substance. The standard tube was next described in detail. A large number of interesting experiments were described and illustrated on the screen. The radiation from the target and stem was beautifully demonstrated by a number of pin-hole photographs. The discovery that X rays are given off from practically the whole of the target and stem was at first a rather disconcerting factor. It became necessary to ascertain the exact effects these rays might have upon the quality of the radiographs. Accordingly,

a number of experiments were carried out to settle this point. A metal hood was placed in relation to the target; in this were two small openings, one in the axis of the cathode stem, the other at right angles to it. It was found that by this method a large percentage of the stray radiations were prevented from reaching the plate. A small metallic screen introduced into the interior of the tube served the same purpose. Dr. Coolidge next proceeded to estimate the effect of these radiations. He found that the percentage of radiation from the back of the tube was roughly one-tenth of that from the front surface. Nevertheless in practical work, so long as the exposures were relatively short, no very obvious effect was observed on the photographic plate. Another most interesting point, from the radiographic point of view, was the influence of the size of the focal spot on the target upon the sharpness of the radiographic image. An ingenious series of experiments was devised in which both the anode and the cathode could be moved either towards or from one another. The results of these experiments had an immediate practical bearing.

Having dealt fully with the experimental data, Dr. Coolidge proceeded to describe and demonstrate the latest forms of the best cathode tube. Recent models have been reduced in size and have been standardised. The small tube consists of lead glass. Opposite the target is a window of ordinary glass which allows the X rays to pass through. The standardisation of the apparatus used for exciting the X ray tube is another development which has now become possible with the best cathode tube. The demand appears to be for a small portable apparatus which will produce good radiographs almost automatically. This has its advantages, but there are also dangers. The simplification of technique may induce medical men who are not familiar with the dangers attendant upon the use of X rays to venture on such work without counting the cost. The latest forms of the Coolidge tube were described and reference was made to the portable form of transformer. The development of apparatus on the lines indicated should lead to simplification of technique and an approximate standardisation of exposures in radiography. The advantages in therapeutic work will then be immediate. With the tube and transformer immersed in oil it should be possible to obtain with care a greater spark length than is possible with the usual method. In air the difficulty is to prevent sparking when high voltages are employed. In Germany, for instance, the Coolidge tube is made with very long terminals, and it is claimed that spark lengths up to 15 inches are employed in therapy. The oil immersed type of apparatus should make it possible to obtain equally high voltages with the small radiation type of tube. This is an advance likely to play a great part in radiography, for the quality of the radiations from one tube can now be varied from $\frac{1}{2}$ inch up to 15 inches spark length, giving a range of wave length which makes it possible to radiograph objects of low atomic weight, such as flowers, at one end of the scale, while at the other it is possible to get a radiograph through 2 or 3 inches of steel. It is difficult to over-estimate our indebtedness to Dr. Coolidge for the valuable work he has carried out. From the medical point of view alone it is sufficient to state that only those radiologists who have had experience of the Coolidge tube in radiography and therapy are in a position to estimate the revolutionary part it is already playing in their daily work. The discovery of X rays by Röntgen was the first step in a new science. The perfection by Dr. Coolidge of the best cathode tube is another of the great landmarks in the history of X rays.

SELF-SUPPLIERS OF MORPHINE IN FRANCE.

As in this country, the sale of morphine to the public in France has recently been drastically curtailed by law, and the interesting point has arisen whether the medical man is or is not subject to the same restrictions as his patient. Certain medical men, accustomed to obtain medicaments for their own use, not merely by signing an ordinary prescription but by giving an order

for them on a larger scale, recently came into court charged with having obtained from pharmacutists quantities of morphine in excess of those prescribed by law for the ordinary patient who is, in addition, obliged to obtain a weekly renewal of his medical prescription. Five of these medical men, who appeared before the judicial tribunal of the Seine, pleaded respectively gout, an affection of the lungs, of the heart, of the nerves, and of the kidneys, along with the right to treat their own maladies themselves if they wished to do so. They were acquitted by the tribunal, which recognised the medical man's right to obtain medicaments wholesale, the verdict running, "the doctor who treats himself does so in the exercise of his profession."

PRECANCEROUS LESIONS OF THE VULVA.

As the normal variations in the senile involution of the vulva after the menopause have received but little attention in anatomical and gynaecological literature Dr. F. J. Taussig,¹ visiting gynaecologist to the Barnard Free Skin and Cancer Hospital, St. Louis, has made a careful study of the vulva in 100 women beyond the menopause, noting the age, number of children, age at menopause, general condition of the skin (dryness, elasticity, freckles, keratosis, naevi, &c.), and the local genital condition (size of labia minora and clitoris, dryness, colour, elasticity, scars, presence of vaginal discharge, &c.). Apart from vulvar atrophy, all forms of which were encountered in the normal vulvar skin at this age, four distinct pathological conditions were found—viz., pruritus vulvæ, kraurosis vulvæ, leukoplakic vulvitis, and carcinoma. Pruritus, which in spite of frequent lack of cleanliness was only rarely present, was not accompanied by vulvar atrophy and showed no tendency to malignant changes. The elastic tissue was of normal amount and distribution. Kraurosis vulvæ was associated with an extreme degree of vulvar atrophy and also showed no tendency to malignant degeneration. In leukoplakic vulvitis the skin changes consisted primarily in an absorption of elastic tissue from the uppermost layers of the corium of the vulva internal to the hairy portion of the labia majora. Although some writers have attributed leukoplakic vulvitis to syphilis, the Wassermann reaction was positive in only two of the present series of 19 cases, and neither of these showed active syphilitic lesions. Moreover, the disease is primarily one of old age, whereas syphilis in an active form occurs chiefly in younger persons. Leukoplakic degeneration shows a marked tendency to malignant degeneration. Perruchet found carcinoma in 16 out of 19 cases, and in Dr. Taussig's series 14 out of 20 cases developed carcinoma. Among 9 cases in which carcinoma was present unassociated with leukoplakic vulvitis, in 2 tertiary syphilitic ulceration was definitely associated with the cancerous process, in 2 there was a definite history of trauma, in 1 the cancer developed from the edge of a typical acuminate wart, and in 4 no ætiological factor could be found.

THE WORK OF THE SCOTTISH BOARD OF HEALTH.

THE first annual report of the Scottish Board of Health, just issued, deals with the year 1919. Schemes for housing are being satisfactorily prepared by local authorities. In consideration of plans submitted, the view has been taken that approval of houses of less than three rooms would not be justifiable excepting in very exceptional cases, and in one instance only have two-roomed houses been agreed to. Endeavour has been made where possible to have houses provided with larger accommodation than three rooms. The cost of the houses still remains unfixed owing to the uncertainty in the rates for wages, cost of materials, and transport. Much time has been spent by the Board in considering the various schemes framed by local authorities for the prevention, detection, and treatment of tuberculosis. The number of institutions approved at the close of the year for the treatment of

tuberculosis was 118, being 96 sanatoriums and hospitals and 22 tuberculosis dispensaries. The number of beds was 2694, being 1 per 1767 of the population. Arrangements for domiciliary treatment continue as before, but the amount allowed per patient for expenditure on medical comforts has been raised from 7s. to 10s. weekly. Scarcity of labour and rise in costs have deterred local authorities from proceeding rapidly with their plans, and the time allowed by the Treasury for the submission of these has been extended. The original grant of £60 per bed in respect of new buildings has been increased to £180 in the period under review. There does not appear to be any drop in the number of discharged soldiers requiring institutional treatment for tuberculosis. The arrangements made provide for priority of treatment, and except in cases where treatment was refused, a suitable period of residence in a sanatorium or hospital has been provided. School medical services suffered severely as the result of the war, but with the return of normal conditions rapid development is expected. These services deal with a total school population of about 850,000. Of these about one-third are systematically examined annually, while a large number are examined as special cases in addition. The Board has in course of preparation a memorandum on school health administration which it proposes to issue to school authorities at an early date. A central register of the blind is now almost complete, and statistics are in course of preparation showing the country, age, occupation, income, and cause of blindness, of all blind persons in Scotland. The number of Approved Societies in Scotland at the close of 1919 was 240, having a total membership on July 1st, 1918, of 1,533,923. A careful scrutiny of official audits continues to be made with a view to pressing societies to remedy defects disclosed. There is a notable improvement in the bookkeeping of the smaller units. Eleven out of 72 Scottish societies have net deficiencies, while of 25 international societies with head offices in Scotland 6 have net deficiencies. Taking all 97 societies together, there is an excess of £32,000 of total surpluses over total deficiencies.

Sir James Mackenzie has been appointed Honorary Physician to the King in Scotland, in the room of Sir Thomas Richard Fraser, deceased.

RESTRICTION OF THE OPIUM TRAFFIC.—The Edinburgh Anti-Opium Committee, formed for the purpose of promoting the objects of the Hague International Opium Convention, states in a pamphlet just circulated that the friends of the anti-opium cause had for years been expecting that when the Hague Convention came into operation the opium traffic in India and all over the world would cease, except for legitimate—i.e., medicinal—purposes. But a letter dated June 26th from the India Office and signed for the Secretary of the Revenue and Statistics Department, contained the passage:—

"The Government of India do not admit that the opium used in India, or exported, is 'abused'; they do not consider it advisable to limit the export of opium from India to the amount required solely for 'medicinal' purposes; and they do not accept the suggestion that India should prohibit the export of opium in order to force, or to attempt to force, the countries which now receive their supplies from India to abandon their present opium policy. In this connexion, I am to point out that the Hague Convention contemplates, and provides for, the use of opium for other than purely medicinal purposes; it does not stigmatise the use of opium for such purposes as an 'abuse'; and it places the responsibility for regulating the import of the drug, and the derivatives, upon the importing country."

The Edinburgh Anti-Opium Committee, which has Dr. A. H. F. Barbour as chairman of its executive, has replied by passing the following resolution, copies of which have been sent to the Prime Minister and to the various heads of the departments concerned:—

"The Committee thank the Government for the prompt introduction of the Dangerous Drugs Bill, and trust that facilities will be given for its speedily becoming law; they, however, desiderate in it more definite restriction of both 'raw opium' and morphia and cocaine to medical requirements, which they believe to be the intention of the Hague Articles, when taken as a whole; they also trust that the provisions of the Bill will be extended to India and other Eastern Dependencies, according to the terms of the declaration of the British signatories at the Hague, which says, 'The Articles of the present Convention shall apply to British India, Ceylon, the Straits Settlements, Hong-Kong, and Wei-hai-Wei, in every respect in the same way as they shall apply to the United Kingdom and Ireland.'"

¹ Archives of Dermatology and Syphilis, June, 1920.

THE BRITISH MEDICAL ASSOCIATION.

EIGHTY-EIGHTH ANNUAL MEETING AT
CAMBRIDGE.

SECTION OF MEDICINE.

WEDNESDAY, JUNE 30TH.

The first session, with Sir HUMPHRY ROLLESTON, President of the Section, in the chair, was occupied with a discussion on the

Nervous Disorders of the Stomach and Intestine.

The opening paper was read by Dr. ARTHUR F. HURST (London), who said that functional disorders of nervous origin were of two kinds: the neuroses, which were independent of mental processes, whether conscious or subconscious; and the psychoneuroses, which had a psychical cause, the latter alone being amenable to psychotherapy. By hysteria he meant a condition in which symptoms were present which had been produced by suggestion and were curable by psychotherapy. He and his fellow-workers had confirmed Babinski's observations that Charcot's physical stigmata were invariably a result of suggestion on the part of the observer, and though an abnormal degree of suggestibility predisposed to hysteria it was not an essential part of it, and hysteria might occur in individuals with a perfectly normal make-up.

The traditional description of the nervous disorders of digestion depended on false ideas of anatomy and physiology. It was assumed that a certain degree of tone and a certain activity of peristalsis were normal, and that a normal stomach secreted juice of a certain strength, and any divergence from these standards was regarded as evidence of disordered function. But his own investigations and the recent chemical investigations by fractional test-meals, carried out by Reyfuss and Crohn in America, and by Ryle and Bennett at Guy's Hospital, had shown that such great variations occurred in the muscular tone, peristalsis, and secretory activity of the stomach in normal individuals that the conditions generally known as atonic dilatation, hyperchlorhydria, and hypochlorhydria might really fall within normal limits. The discovery of variations from the average normal tone, peristalsis, and secretion in persons with digestive symptoms was therefore no evidence that these variations were in any way responsible for the symptoms.

There was not the smallest evidence to show that true neurasthenia in any way affected the motor or secretory functions of the stomach. Though there was little justification for retaining such terms as atonic dilatation of the stomach, hyperchlorhydria, hypochlorhydria, atonic and acid dyspepsia, as descriptions of clinical conditions, there were two varieties of neurasthenic dyspepsia which could only be recognised with certainty with the aid of X rays and gastric analysis—the atonic, occurring in an individual with a stomach having less than the average tone and secretion, and the hypertonic, occurring in one with a stomach with more than the average tone and secretion.

Hysterical vomiting was a condition that occurred frequently, especially in gassed soldiers. Whatever its original cause, auto-suggestion led to its aggravation whilst the primary cause was still present, or to its perpetuation after the latter had disappeared. He came to the conclusion that whenever vomiting persisted for more than a month after gassing it was certainly hysterical. The most important of all forms of hysterical vomiting, which had led to the death of many mothers and of still more unborn infants, was the so-called "pernicious vomiting of pregnancy."

Dr. Hurst had not yet seen a case in which immediate recovery did not follow psychotherapy. It had been proved conclusively that the disturbed metabolism was due to starvation and dehydration, and was not an indication of some obscure toxæmia. We were often too ready to accept our patient's own diagnosis. He said he was suffering from flatulence, and we treated him with diet and antiseptic drugs for flatulent dyspepsia. Careful investigation had shown that fermentation very rarely occurred in the stomach, which empties itself too rapidly and secretes a juice which is too acid for any appreciable amount of bacterial activity to occur. The only common cause of flatulence was aerophagy, which was a psychoneurosis, and, like all hysterical symptoms, could be readily cured by pure psychotherapy.

Passing to nervous disorders of the intestine, Dr. Hurst said that in his experience the symptoms generally ascribed to auto-intoxication caused by intestinal stasis were really produced by purgatives, which led to the absorption of excess

of toxic material, partly by hastening the half-digested contents of the small intestine into the cæcum, where fermentation and putrefaction were consequently increased, and partly by causing the contents of the transverse, descending, and pelvic colon to be fluid instead of solid, so that absorption of toxins took place throughout the length of the bowel instead of in the cæcum and ascending colon alone. The majority of cases of dyschezia, or inefficient defæcation, which was the commonest form of severe constipation, were of nervous origin. In many cases no treatment was required beyond explaining to the patient the nature and cause of his condition and persuading him to make an effort to empty his rectum, but occasionally it was also necessary to re-educate the rectum with graduated enemata. When a patient complained of auto-intoxication and intestinal stasis, and gravely discussed the question of kinks and adhesions, producing a diary in which every motion he passed was minutely described, the diagnosis of intestinal hypochondriasis was obvious. The patient should be taught that his auto-intoxication was the result of drugging, that intestinal stasis in moderation was a virtue, as it promoted digestion and absorption of his food, and that we all had kinks and adhesions, and so long as they remained in the abdomen and did not get on the brain they did not really matter. He alone was happy and devoid of that most trying of nervous disorders of the bowel—hypochondriasis—who followed Sir James Goodhart's admirable advice to do as the dogs do and never look behind him. Nervous diarrhœa occasionally occurred which might be considered hysterical, but it was necessary in every case to discover what was the nature of the suggestion which caused the diarrhœa. In most cases the original attack of diarrhœa was emotional in origin, over-activity of the bowel being one of the rarer of the many physical symptoms of emotion. The symptoms having been caused by suggestion could be cured by psychotherapy.

Muco-membranous colitis when not associated with organic disease might be regarded as a neurosis, as it occurred in exhausted individuals whose nervous systems had become abnormally irritable. So long as the patient did not know she was passing mucus she was comparatively well, but when a course of Plombières treatment had made her a connoisseur in fæces a mental element was added which it was often difficult to remove. But get her away from her devoted parent, her purges, and her Plombières and she would soon be free from her psychoneurosis; the muco-membranous colitis, the pure neurosis, might still be present, though it required but little treatment beyond wholesome neglect.

In conclusion Dr. Hurst hoped the discussion would lead to a satisfactory classification of gastric and intestinal neuroses based on observed facts.

Dr. T. I. BENNETT gave a demonstration by charts shown on the screen of the result of some of the investigations which he had made on the secretory functions of the stomach, assisted by several students of Guy's Hospital. Chemical examinations were made every quarter of an hour of the contents of the stomach. He found that the estimation of the acidity of the gastric contents was often grossly fallacious, as he had discovered both hypochlorhydria and hyperchlorhydria in perfectly normal students. He had proved the profound influence of the nervous system on the chemical constituents of the stomach by hypnotising individuals while test meals were being given. A suggestion of hunger caused a marked rise in the HCl curve, and the rate of emptying the stomach was much affected by various emotional suggestions.

Dr. T. R. BROWN (Baltimore) considered that it was a dangerous doctrine to promote that all the cases in question were of nervous origin. Cases frequently occurred which were at first supposed to be hysterical, but afterwards turned out to be of organic origin. He specially referred to obscure cases of gall-bladder disease which were often unrecognised at first. He thought a fundamental principle to apply was that enunciated by Sir Clifford Allbutt—that everything in disease was correlated. The patient should be studied by every known method before coming to the conclusion that the disease was not organic.

Dr. LANGDON BROWN (London) agreed that cases which were supposed to be neurotic often turned out to be of organic origin. He made some observations about the distribution of the nerves of the stomach, and protested against the too rigid diet often ordered in diseases of the stomach. We should make sure that if our treatment did no good it should not at least do any harm.

Dr. J. A. NIXON (Bristol) thought too much stress should not be laid on the psychical factor in these diseases, as there was a danger of overlooking the organic basis, which might be a very small one.

Mr. H. TYRRELL GRAY (London), speaking from the point of view of a surgeon, thought that any advance in the diagnosis of these diseases was to be brought about by a closer association between the physician, the surgeon, and the physiologist.

Professor R. J. BUCHANAN (Liverpool) expressed his belief in hysterical stigmata, a striking instance of which he related, the subject being a man one side of whose face was found covered with flies quite unknown to him, the condition being anaesthesia of that part. He said there were two schools of thought on the subject—the physical and the psychical—but it was necessary to study the subject in all its aspects. In his opinion functional diseases of the stomach were becoming fewer and organic affections more common, and the diagnosis of "hysterical stomach" was often due to the exhaustion of diagnostic resource.

Dr. W. J. TYSON (Folkestone) confessed his inability to diagnose these cases, and remarked how some of them got well after operation and others got well without operation. He did not think we had reached bottom at all in the diagnosis of these cases, but he thought Dr. Hurst's paper would do an immense amount of public good if it checked the self-prescription of purgatives, though he feared it would interfere with the trade of the chemists.

Lord DAWSON said that organic disease often began in a most insidious way. If he made a diagnosis of nervous dyspepsia in a patient he constantly reviewed that diagnosis and tried to upset it if possible. It was important, however, to give the patient a definite diagnosis, for which reason he approved of the term "colitis." There was a danger of allowing patients to become too introspective, and he always found doctors and nurses the worst patients, as they were inclined to attribute their symptoms to the very worst forms of disease they knew of.

Other speakers in the discussion were Dr. R. G. GORDON (Bath), Dr. E. HOBHOUSE (Brighton), Dr. LIBMAN (New York), Dr. CRAVEN MOORE (Manchester), and Dr. R. C. PARSONS (Dublin). The general opinion seemed to be that there was a danger of laying too much stress on the neurotic element, and thus possibly overlooking organic changes and of trusting too much to psychoanalysis.

Dr. HURST replied, and stated that his method of psychoanalysis simply consisted in a close cross-examination of the patient and an endeavour to ascertain the origin of the symptoms.

THURSDAY, JULY 1ST.

Interest in the second day's proceedings was evidenced by a crowded meeting of members, the subject for discussion being the

Present Position of Vitamines in Clinical Medicine.

The opening paper was read by Professor F. GOWLAND HOPKINS (Cambridge), who said that the modern conception of a deficiency disease was not, of course, based wholly upon a belief in the existence of vitamins. There might be quite other factors of deficiency in a diet which might produce symptoms to be observed clinically, but the hypothesis of vitamin deficiency played a large part in current views concerning the chief examples of the conditions to be discussed.

Professor Hopkins described certain experiments which he had performed, which dealt with the conditions which affected the stability of the so-called fat-soluble vitamin, and the results showed definitely that oxidation played a much larger part in the conditions which destroyed it than did temperature.

Curves were shown on the board which represented average body-weight changes in two strictly comparable groups of rats. The two groups were fed side by side on a dietary absolutely identical in every particular save one. In the food of one set the fat was butter which had been heated for four hours to 120° C., but heated without aeration. The fat given to the other set was the same butter heated in exactly the same way, but during the heating a stream of air was bubbled through the melted fat. As the curves showed, growth in the first set was perfectly normal, while in the

case of the second set, though the rats consumed the food satisfactorily, growth continued but for a short time, and the rats then steadily lost weight. Shortly after the end of the period covered by the curves (some 60 days), while the first set of rats remained in perfect health, all those in the second set were dead.

It was easy to show that nothing toxic developed in such aerated fat. Animals taking it in their food after a relatively small amount of normal unheated butter had been mixed with it were maintained in health, and if half of it had been replaced by normal butter they grew well. Clearly the treatment had produced some deficiency. That it was legitimate to speak of the effect as one involving a destruction of the fat-soluble vitamin was shown by the fact that the rats fed on the altered butter showed just those appearances which were peculiar to others fed upon such vegetable fats as were believed to be free from that substance. The suggestion of the experiments was that the vitamin had considerable heat-stability, but that it was easily oxidised—a point of some practical importance.

It was most important to remember that the absence of a specific factor from the food produced results very different from those that followed actual starvation. In the latter case the energy requirements and other demands were met from the tissues, and there was rigid economy of effort and material. But when an individual's diet was deficient in a vitamin he might still be dealing with large quantities of total food. The metabolic machinery might be working at full pressure while nevertheless deprived of some essential wheel or cog.

If there was one clinical condition in which the influence of a deficiency seemed obvious, direct and but little complicated, it was certainly scurvy. There was no more striking evidence to show that the antiscorbutic substance (if there was only one) was of a special nature, coming under the definition of the vitamin, than the fact that while absent from dry grains it appeared suddenly when the grains germinated.

There was no doubt about the prime importance of the food factor in treatment. The recent quantitative studies at the Lister Institute had yielded results of extraordinary importance, and would put the therapeutics of scurvy upon a really scientific basis. The so-called xerophthalmia, which was a late result of feeding animals upon food from which the fat-soluble accessory was absent, was an extraordinary phenomenon, coming on very suddenly about the fortieth or fiftieth day of deprivation. It commenced as a corneal opacity, and often in a few days there was complete panophthalmitis; the cornea might perforate and the lens extrude. Caught at an early stage the process could be wholly arrested by administering butter, cod-liver oil, or any substance containing the fat-soluble accessory, though in no other way.

The question of rickets was one which was still much debated, some observers believing in the prime importance of defective hygiene in its aetiology, and others pinning their faith to vitamin deficiency as its causation. Professor Hopkins remained a firm believer in the influence of a specific diet deficiency, at least, in experimental rickets as displayed by dogs, because in Dr. and Mrs. Mellanby's experiments he had seen carefully controlled observations showing unequivocal results. Other experiments, especially those of Dr. Hess and Dr. Unger, seemed to show that deficiency in the fat-soluble vitamin had little to do with rickets. That more than one factor was concerned in the causation of rickets seemed sure; their relative importance remained yet to be determined.

Sir JAMES BARR (Liverpool) said that he had recently had a conversation with a director of one of the largest manufacturing factories of margarine in the United Kingdom, turning out 3000 tons a week, who told him that margarine usually gave rise to rickets, but they were determined that their margarine should not soften the bones of children or any other animal. On scientific advice they were recommended to add a certain proportion of animal fats, but as these were not obtainable they tried the next best thing—viz., yolk of eggs, and they therefore added 64 yolks to each ton of margarine. As he himself ate two eggs every day he found he would have to consume 70 lb. of margarine daily to obtain the necessary vitamins. He therefore preferred to wait until it was available in tablet form. He considered that vitamins were an indispensable substance or substances, which had never been isolated and whose composition was uncertain. He preferred lymphagogues, like calcium salts, of which he knew something, and would allow others to swallow tons of unpolished rice in order to get some imaginary vitamins about which they knew nothing.

Dr. HARRIETTE CHICK and Dr. ÉLSIE DALYELL gave an interesting account of their experiences and experiments in Vienna, and threw on the screen several remarkable photographs of children, and charts showing the emaciated condition of these children and extreme conditions of rickets, all of which had been immensely benefited by adding to their diet various fat-soluble substances, such as butter and cod-liver oil, and also by administering antiscorbutics.

Lieutenant-Colonel R. MCCARRISON, I.M.S., said that on the previous day, in the Section of Tropical Medicine, he had emphasised the effects on the endocrine organs of four factors:—

- (1) Deficiency of vitamins.
- (2) Deficiency of soluble protein.
- (3) Disproportionate richness in the dietary of starch or fat, or both.
- (4) The fortuitous occurrence of pathogenic agents in the body.

To-day he wished to emphasise the same thing in the causation of deficiency diseases, such as rickets and scurvy. He exhibited on the screen several photographs of the stomach and intestines of monkeys, and believed that the same conditions occurred in human beings. In general the symptomatic manifestations of dietetic deficiencies were:—

- (1) Dilatation of the stomach; (2) indigestion; (3) deficient action of the liver and pancreas; (4) air locks in the small intestine; (5) failure of neuro-muscular control of the gastro-intestinal tract; (6) a tendency to intussusception and to the formation of gastric ulcer; (7) most important of all, colitis.

He had found that when monkeys were fed on a diet excessively rich in starch there was an increase in the weight of the brain by one-seventh of the normal, and this would give rise to confusion of ideas.

Dr. ALFRED HESS (New York) referred to the value of dried milk, 2 oz. of which were equivalent to 1 pint of fluid milk. He said that beneficial results from dried milk depended on the kind of milk used in its preparation; the milk must have been obtained from cows receiving a liberal ration, and must have been dried quickly. With regard to vegetables, an important factor was the soil on which they were grown. He had found that one diet which gave rise to rickets was the so-called protein milk diet. Precipitation of the curds by means of heat led to rickets in about 75 per cent. of babies. He regarded cod-liver oil as almost a specific for rickets.

Dr. G. F. STILL (London) suggested as a reason why some infants did not suffer from scurvy though fed on similar food to those who did develop the disease that those who were at first immune started life with a certain capital of vitamins derived from their mothers, that they lived on this capital for a time, but sooner or later became bankrupt as far as vitamins were concerned. Certain proprietary foods figured much more largely in the history of scurvy than others, and he had seen several cases in which fruit juice had been given for months without preventing the disease. He had found baked potatoes a most important prophylactic of scurvy, but believed, like Dr. Hess, that the soil on which the potato was grown, or the particular kind of orange, or its degree of ripeness, were factors to which sufficient attention had not been given. At present one waited on the bio-chemist for the possibility of stating the exact value of any particular food in units of vitamin. When he was able to do that we should have a means of exact clinical investigation and treatment which at present was lacking.

Dr. LEONARD WILLIAMS (London) said that the community at the present day was hypercivilised. If we knew anything of vitamins it was that they were contained in uncooked food. The community lived upon food from which vitamins were rigidly excluded. We boiled our milk, steamed our vegetables, and cooked our fruit. That was done from a combination of pleasure and fear; pleasure, which he confessed that he himself shared in the enjoyment of the foods so cooked, and fear of the microbe. In cooking it was not only the vitamins which were destroyed but other vitalisers. In our insane fear of our enemies we slaughtered our best friends. An uncooked dietary was, in his opinion,

specially good in rheumatism and middle-aged arthritis, also in gastric and duodenal ulcer, and with its adoption constipation and intestinal stasis disappeared. Its results were no less wonderful than those of the thyroid treatment of myxœdema.

Dr. W. H. WILLCOX (London) referred to experiences in the Mesopotamian campaign, in which scurvy and beri-beri occurred to a great extent.² Owing to the intense heat and the difficulties of transport, the provision of supplies of fresh fruit and vegetables to the troops in the fighting area was impossible for a certain period. A most serious outbreak of scurvy occurred among the Indian troops in 1915-16. There were over 11,000 cases from July 1st to Dec. 31st, 1916. The men's diet was adequate in calories, having sufficient protein, fat, and carbohydrates, but was entirely free from antiscorbutic vitamins. As soon as it was possible to issue articles containing the necessary accessory food factors the epidemic ceased. Cases of beri-beri also occurred among British soldiers, but the Indian troops remained free from beri-beri, because the main part of their diet consisted of atta—a coarsely ground wheat flour containing the germ and aleurone layers of the grain, in which the necessary accessory food factors were present. They also had a daily allowance of 4 oz. of dhall, small lentils, whole or split.

Dr. ERIC PRITCHARD (London) said that none of the theories as to vitamins explained the pathology of rickets. All conditions of malnutrition created a demand for calcium, and in rickets the bones were starved because the calcium was required for more important purposes. Rickets was more properly called an excess disease than a deficiency disease, and it would be more appropriate to call it a condition of want of balance.

The following speakers also took part in the discussion: Dr. J. C. DRUMMOND, Dr. H. C. CORRY MANN, Dr. S. MONCKTON COPEMAN, and Dr. R. L. MACKENZIE WALLIS (all of London), Dr. C. MUTHU (Wells), and Dr. J. BROWN (Blackpool); and Professor HOPKINS replied.

FRIDAY, JULY 2ND.

A discussion on the clinical significance and course of

Subacute Bacterial Endocarditis

was opened by Sir THOMAS HORDER, who said that we must exclude from our view rheumatic endocarditis, ulcerative endocarditis, which was but a part of an acute pyæmia, and that form of bacterial endocarditis which occurred as a terminal event in chronic diseases. Subacute bacterial endocarditis was the accepted name of a disease having more or less of the following features. The onset was most often insidious; the general symptoms included loss of strength and tone, a sallow complexion with anæmia, moderate loss of weight and fever; the heart gave evidence of endocarditis at some time or other in almost all cases, and in the majority there had been previous valve injury; widespread arterial embolism occurred; in most cases blood cultures were positive, the isolated bacterium being either a short streptococcus, much less often Pfeiffer's bacillus, and rarely a micro-organism difficult of identification, but in all cases the microbe was of low pathogenicity. The course of the disease was slow but progressive, and although remissions occurred, it was, once established, almost invariably fatal. The total duration of the illness was from three months to two years, with an average duration of six months; death occurred from toxæmia, from heart failure, from anæmia, or from cerebral or coronary embolus. The post-mortem findings included a vegetative endocarditis on the valves or wall of the heart, with little or no ulceration, and widespread embolic infarction without suppuration. As a result of the embolic process there was found a form of glomerular nephritis more or less characteristic of the affection. The disease was fairly common. From his own investigations he had found that 1 in 200 patients admitted to the medical wards of a large general hospital suffered from subacute bacterial endocarditis.

² THE LANCET, 1917, ii., 677.

Most of the cases occurred between the ages of 15 and 50 and half of them between 20 and 40. In about half the cases met with there was a history of acute or sub-acute rheumatism or chorea. The existence of old-standing valve lesions was of great importance in the aetiology. There were four cardinal signs of the disease when it was fully evolved. Arranged in the order of their importance from the point of view of diagnosis they were: multiple arterial embolism, endocarditis, the isolation of a bacillus from the blood stream, and fever.

1. *Multiple arterial embolism.*—Close study of the clinical and of the morbid anatomical material available revealed the facts that many more organs and tissues were found to be affected by infarction than was formerly known to be the case, and that many of the emboli were of microscopic size, little else than microbic metastases in fact. These two considerations were of very great importance in the clinical and clinico-pathological investigations of a suspected case. Petechiæ on the skin were very frequent harbingers of more certain signs. Isolated and pioneer petechiæ were common about the regions of the clavicles and at the base of the neck; those situations should be carefully examined. Even more decisive from their diagnostic significance were the painful and discoloured patches or nodes that appeared on the terminal phalanges of the hands and feet, especially on the pads of the fingers and toes. Those patches were doubtless embolic in origin, the affected vessel lying in the deep layer of the skin or in the soft parts beneath the skin.

Many of the symptoms referable to joints and peri-articular structures were doubtless embolic in origin, as they lacked the symmetry of true rheumatic joint affections, there was much less tendency to synovial effusions, and focal oedema and discolouration were common in the overlying skin. Also the situation of the pain and swelling was not seldom one rarely seen in true rheumatism—e.g., the dorsum of the foot, the region of the tendo Achillis, the groin, the sterno-clavicular joint. Gross embolic infarction of the kidney, accompanied by severe pain, hæmaturia, and albuminuria, was, of course, well known. Less widely known, but of great importance, was the occurrence of very minute microbic embolisms in the kidney glomeruli, which was to be inferred clinically by the discovery of red blood-cells and traces of albumin in the urine of suspected or known cases. The urine should be examined systematically over a series of at least ten days, to prove or exclude this glomerular infarction. Small hæmorrhages were also frequently found in the retina.

2. *The endocarditis.*—This might be manifest or it might be masked. When evidence of endocarditis was found it must be remembered that it might be due to old-standing cicatricial changes in the valves, though it was most probably caused by the recent infection. There was, however, general agreement as to the fact that for the major part of its course subacute bacterial endocarditis was very largely destitute of cardiac features. Indeed, our conception of the disease would be in stricter accord with the facts both of clinical and of morbid anatomical observations if we did not regard it as a disease of the heart at all. In this respect it contrasted markedly with acute rheumatism.

We should therefore avoid the error of thinking a patient was necessarily free from the suspicion of infective endocarditis because his heart and pulse on critical examination showed little or no evidence of disordered function, such as arrhythmia, symptoms of inadequate response to effort, or signs of dilatation.

3. *Isolation of microbes from the blood stream.*—Since we had become more familiar with the disease the confirmatory evidence of a positive blood culture was less essential to a correct diagnosis. Sir Thomas Horder regarded a series of negative blood cultures—assuming a competent bacteriologist—as indicating some as yet unknown factor determining the content of the microbe in the circulating blood rather than as indicating that the vegetations were "bacteria-free." They must beware not to assume a better prognosis in the cases in which blood cultures were negative.

4. *Fever.*—This was probably an invariable concomitant of the disease, and its discovery was the commonest early hint that all was not well with the patient, and it was the symptom which brought most patients under observation. Though the pyrexia usually persisted, yet there were often afebrile periods, sometimes lasting for 10 or 14 days, which were often accompanied by increased tone in the patients, and presumably by remissions in the systemic part of the infective process. The afebrile periods preceding the end of the disease were but a sign that the tissue response to stimulation was at last exhausted, that an asthenic stage had arrived, and that the end was near.

In conclusion, the speaker suggested several points for discussion and elucidation, particularly the nature

of the infecting organism and its possible habitat in the tonsils, periodontal membrane, and appendix; the importance of a previously damaged heart as a factor in the causation of the disease; and whether in our treatment we should do best to concentrate our attention chiefly on the streptococcus, or try still more diligently than hitherto to find a successful system of chemotherapy, or spend our efforts largely in non-specific measures, with a view to raising the general resistance, as was the present method of dealing with pulmonary tuberculosis.

Dr. E. LIBMAN pointed out the difference between the pathological findings in rheumatic endocarditis and subacute bacterial endocarditis. In the former the vegetations were small, firm, and covered by endothelium, and in the heart muscle the Aschoff bodies were found, whereas in the latter an entirely different type of lesion was found in the heart muscle—viz., the so-called Bracht-Wachter bodies—and in the kidneys were found the almost pathognomonic focal glomerular lesion described by Lochlein and others. There were two groups of cases of bacterial endocarditis, the acute and the subacute. The acute cases were caused by hæmolytic streptococci, pneumococci, staphylococci, and other organisms. Ninety-five per cent. of the subacute cases were due to non-hæmolytic streptococci; the remainder were almost entirely due to influenza bacilli.

A pathognomonic symptom of the subacute cases was the tender cutaneous nodule, or Osler's node. Other characteristic features were petechiæ having white centres and emboli. Whereas the virus of rheumatic fever and of syphilis attacked normal valves, the infection by non-hæmolytic streptococci of subacute bacterial endocarditis occurred nearly always in valves previously damaged by rheumatic fever. A small number of these subacute cases recovered completely. Dr. Libman had seen four recoveries. About one-fourth of the cases of infection of the valves of the heart by the non-hæmolytic streptococcus recovered spontaneously from the infection without having been known to have the disease. Many cases presented a remarkable clinical picture that was formerly not understood. They had a valvular defect, and presented evidences of renal insufficiency, progressive anæmia, or embolism. Some had a very large spleen, and were mistaken for cases of Banti's disease. Others developed a remarkable dark-brown colour in the face.

There was no method of treatment of this disease that was of any value. It was therefore important to plan a campaign of prevention. All cases of valvular disease should be periodically examined for foci of infection, the teeth, tonsils, and accessory sinuses being the important avenues of entry of the bacteria. Persistent immunisation should be attempted. The importance of this plan of prevention could be realised by the fact that subacute streptococcal (and influenzal) endocarditis caused one-third of the deaths due to valvular disease, and that it attacked, in the main, young people not yet incapacitated by their cardiac inefficiency.

Dr. T. WARDROP GRIFFITH (Leeds) remarked that subacute bacterial endocarditis was characterised by symptoms which were much less mechanical than in the other varieties of endocarditis. The disease produced chemical rather than mechanical effects.

Dr. F. J. POYNTON (London) showed several slides which exhibited bacterial infection in cases of rheumatic endocarditis. In his view subacute bacterial endocarditis always occurred in persons who had originally suffered from rheumatic endocarditis, from which they had temporarily recovered only to be attacked later by microbic invasion in their damaged hearts.

Dr. CAREY F. COOMBS (Bristol) said that in rheumatic carditis the whole heart was affected, and not the valves only, whereas subacute bacterial endocarditis was a valvular lesion primarily. Syphilis was an occasional forerunner of bacterial endocarditis, and some cases could be traced to congenital anomalies; but the most frequently pre-existing disease was rheumatism, and therefore the most important factor in its prevention was the prevention of the incidence of rheumatic attacks.

Dr. A. G. GIBSON (Oxford) laid particular stress upon the search for petechial hæmorrhages and for the presence of blood in the urine as an indication of the existence of the so-called "flea-bitten kidney."

Dr. J. HAY (Liverpool) emphasised the following important clinical points:—

1. An increased tendency to a rapid action of the heart (over 100). He did not attach much importance to extrasystoles. 2. Clubbing of the fingers was quite noticeable early in the disease. 3. Malaise, together with a cardiac murmur, arrested attention and necessitated investigation. 4. Pyrexia. 5. The spleen was enlarged at an early stage.

The diagnosis could be, and ought to be, made clinically, independently of blood examination. From the point of view of prevention the rheumatic stage was the only one that mattered. Every patient who suffered from valvular disease of the heart should be thoroughly overhauled from time to time, and here they must fall back on the general practitioner, who must recognise the position of affairs and prevent the development of the disease.

Dr. A. E. GOW (London) referred to the occurrence of recurrent transient erythema involving the inner side of the calf or the trunk, which he had noticed as a symptom of the disease, and which he believed to be toxic in origin.

Dr. H. J. STARLING (Norwich) related his experience of 38 cases which had occurred among soldiers. In his opinion the chief diagnostic points were:—

1. Insidious onset. 2. Pallor, the face having a pale primrose-yellow colour. 3. Endocarditis; all his patients had valvular lesions. 4. Clubbing of the fingers; present in 76 per cent. of the cases. 5. Enlargement of the spleen; occurred in 81 per cent. 6. Petechiae were present in 58 per cent. 7. Osler's nodes were only found in six cases. 8. Gross embolic phenomena occurring in large vessels—in 37 per cent. 9. Absence of pyrexia. Fever when it occurred was dependent on embolism.

He had particularly noticed the occurrence of the disease in a fine type of man: 11 of his patients had never suffered from any illness either before or during the war; 12 had had over three years' service in the army, and 15 over four years' service. Post mortem the vegetations found on the valves were calcareous, and in some cases he had noticed a curious condition of the aortic valves, two of the cusps being completely fused together. The spleen was found enlarged in all the autopsies except one.

The following speakers also took part in the discussion:—Dr. THOMAS LEWIS (London), who presided at this session, laid particular stress on clubbing of the fingers as a sign of the disease, and pointed out that petechial hæmorrhages occurred in the form of a ring rather than a spot, and were often situated round the clavicle; Dr. J. M. COWAN (Glasgow); Dr. G. D. LAING (Limpfield); Dr. R. J. BUCHANAN (Liverpool); and Dr. E. P. FOULTON (London) and Sir THOMAS HORDER replied to various points raised during the course of the discussion.

SECTION OF PATHOLOGY AND BACTERIOLOGY.

WEDNESDAY, JUNE 30TH.

Professor J. LORRAIN SMITH presided, and the session opened with a discussion on

Liver Atrophy.

In the unavoidable absence of Professor STUART McDONALD (Newcastle-on-Tyne) the discussion was opened by Dr. J. MILLER (Edinburgh) and Dr. A. RUTHERFORD (Edinburgh). From a study of their material, which included 15 unpublished cases, they were able to obtain a very complete picture of the morbid changes in the various stages of the disease.

Three types of atrophy—the acute, the subacute, and the chronic or cirrhotic—were distinguished. The latter is termed by the authors "multiple nodular hyperplasia." In the acute form there was more or less complete destruction of the liver parenchyma with a minimum of reaction. The subacute type showed vascular and inflammatory cell reaction, a proliferation of the smaller bile channels, and commencing formation of connective tissue. In multiple nodular hyperplasia regeneration was the prominent feature, the organ showing oedematous nodules of liver tissue and being small or large according to the degree and extent of regeneration. There was no hard-and-fast line between this type and so-called alcoholic cirrhosis, but the age of incidence and possibly the causation were different. Lantern slides and drawings illustrating

the macroscopical and microscopical appearances of the various types were then shown. As regards ætiology there was no single cause of acute yellow atrophy. Indeed, a striking point in most of the clinical histories was the number of diseases which preceded or accompanied the liver condition. The most frequent were tuberculosis, syphilis, typhoid, influenza, and scarlet fever. In some cases a single virulent poison caused complete destruction of the liver; in others there was a series of attacks on the liver parenchyma. Death might occur at any stage of the disease, but in the chronic condition the patient was likely to survive for an indefinite period. He was, however, very liable to succumb to intercurrent infection.

Dr. B. H. SPILSBURY (London) said that on investigation of the morbid processes in the liver many conditions were found in which atrophy of the parenchyma resulted from the contraction of scar tissue formed in the course of an inflammatory or toxic process. Such conditions were alcoholic cirrhosis, chronic perihepatitis, and congenital syphilis. In acute yellow atrophy the process was essentially a toxic degeneration of the liver cells with areas of necrosis, and the patient seldom survived long enough for fibrosis to occur in the organ. Fibrosis was, however, found in the subacute form of the disease. In poisoning by T.N.T. and tetrachlorethane there was rapid necrosis of the liver cells, or, where the action was less marked, fatty degeneration which might be followed by necrosis. After a longer period fibrosis occurred with compression atrophy of the remaining liver substance. Scarring of the liver would probably be found post mortem in many cases which had recovered from T.N.T. poisoning.

Mr. A. G. R. FOULERTON (London) dealt with fatty changes in the liver and kidneys caused by various poisons both in the human subject and in experimental animals. He dwelt on the fact that with the exception of arsenic, antimony, and mercury, these poisons are all either fat solvents or are soluble in fats. He considered that the food fat, which is normally mobilised in the liver, reaches the organ combined with a large amount of the poison. The latter destroys the liver cells, which are then unable to deal with the fat. Some of the unaltered fat finds its way to the kidney, which likewise succumbs to the effect of the poison. This theory, which is confirmed by experiment, explains the widespread lesions in the liver and the nephritis which is the common accompaniment of the condition.

Dr. WILLIAM HUNTER (London) considered that the fatty changes in liver and kidney are due to cell degeneration or to the unmasking of fat previously present in the cell. In his view the poison affects every cell in the body simultaneously. If the lesion is severe enough to put the liver out of action the proteolytic ferments which it contains will digest the liver cells and cause the universal destruction which is so marked in the disease. The clinical symptoms are caused by the toxic products from the portal blood and from the liver itself escaping into the circulation.

Dr. MATTHEW J. STEWART (Leeds) spoke of the ætiology of the disease and of the morbid changes in the liver in the cases which had come under his notice. He had followed up several cases of T.N.T. poisoning with symptoms of acute yellow atrophy, which had recovered. The majority of patients were in excellent health; the only symptoms complained of in one or two instances were occasional bilious attacks and epigastric pain.

Dr. J. W. MCNEE (Glasgow) described the changes found in the liver and kidney in Weil's disease. In his experience there had not been any fatty change in the liver or kidneys, although acute nephritis was present. He thought that further work was required on liver function in normal and pathological conditions.

Dr. RUTHERFORD and Dr. MILLER replied.

THURSDAY, JULY 1ST.

Present Position of Cancer Research.

The discussion was opened by Dr. J. A. MURRAY (London), according to whom cancer research presents "a restless complication of bold hazards and miserable disappointments." The difficulties which beset the investigator are not always understood by the public, who regard with a certain impatience the detailed

nomenclature and classification of tumours. They do not understand the very rigid criteria to which a so-called cancerous growth must be subjected before its malignant nature is accepted by the research worker, especially where a so-called "cure" has been proclaimed. These criteria are still mainly clinical—e.g., the progressive character of the growth, the formation of metastases, &c. In animals successful transplantation to normal individuals of the same species is often considered the only valid proof of malignancy, though possibly the establishment of artificial metastasis by autologous grafting is a more just test.

The outstanding achievement of experimental cancer research during recent years was Jensen's discovery of acquired resistance to grafted cancer following an unsuccessful inoculation. Unfortunately, no effect is produced on spontaneous growths by this line of treatment, though, curiously enough, animals can be rendered resistant to a secondary inoculation of the same or another carcinoma without modifying in the slightest degree the progress of the established tumour. The resistant state only lasts a short time. It is accompanied by the appearance of plasma cells in the connective tissues throughout the body. According to some workers immunity is associated with an increase in circulating lymphocytes. It is found that X radiation in rats and mice produces a lymphocytosis or a lymphopenia according to dose, and the increase of lymphocytes is accompanied by increased resistance, their diminution by diminished resistance to implanted cancer. Exposure to a hot dry atmosphere, which is also accompanied by lymphocytosis, appears to prevent the development not only of homologous, but also of autologous grafts. These results, if confirmed, are extremely important, since it has hitherto been impossible to influence the growth of transplanted cancer in the same animal.

Direct attacks on the clinical and therapeutic side of the problem of cancer have so far failed in their object. Probably our knowledge of the fundamental processes of cell life is not yet sufficiently advanced for the purposes of cancer research. The problem as to why the cancer cells are uninfluenced by the forces limiting the increase of healthy or diseased tissues is still unsolved.

Dr. H. J. CAMPBELL thought that carcinoma possibly represented an attempt on the part of the organism to reproduce itself by budding. Growth takes place in organs which are undergoing regression and yet have a plentiful blood-supply. Under such circumstances cells tend to revert to the germinal type. Given a superadded local irritation and a hereditary tendency, cancer is likely to supervene.

Dr. A. LEITCH (London) said that inoculation experiments had been of very great service in clearing the ground and defining the extent of our knowledge. None of us, however, would deduce a theory of cancer from them. He touched on the difficulty of distinguishing between innocent and malignant tumours, and gave parotid tumours as an example. In animals the biological test could be performed, though it was not absolutely conclusive. A tumour might become malignant after transplantation when the original growth was innocent. Artificial resistance, which is produced by unsuccessful inoculation of tumours, is not a true biological immunity. It is not possible to immunise an animal against its own tumour. There are no serological differences between normal and resistant mice, and none of the serum reactions devised for the detection of carcinoma in the human subject have been of any value. Future bio-chemical research may reveal differences between normal and cancerous cells; until then serological methods of diagnosis were unlikely to succeed. Treatment of cancer by radium had always interested him, but he had never seen a cure.

Dr. S. RUSS (London) referred to Murphy and Morton's experiment subjecting animals to cancer inoculation after exposure to heat. These workers also removed growths from animals, subjected them to X rays, and then reinoculated them, with the result that the tumours did not grow. The function of the lymphocyte was not exactly known, but lymphocytic activity was observed round grafts in immune animals. Nevertheless the number of circulating lymphocytes could be increased by X rays without producing immunity, so that some intermediate reaction was probably required. The difference between homologous and autologous grafts is one of degree. If a batch of animals are inoculated the

tumour grows very differently in different animals. In some the growth is progressive, in others the tumour vanishes, and all stages are found between. All animals develop some resistance to grafting, but the degree varies greatly. Dr. Russ made X ray experiments on the production of immunity with the object of applying the results to man.

Dr. J. C. MOTTRAM (London) said that Dr. Murray had very shrewdly touched every important aspect of the cancer problem, but both he and Dr. Leitch took an unduly despondent view of cancer resistance. Cancerous tumours exhibit very different degrees of virulence, and certain species of animals are more susceptible to cancer than others. Heredity is an important factor. Natural resistance is sometimes very high, and, rarely, spontaneous cancer may be absorbed. Artificial resistance is increased by various means, such as grafting embryo tissues and small doses of X rays. Induced resistance, however, is never able to completely protect all normal animals. Our methods of protection are too feeble at present to have effect against spontaneous cancer.

Dr. SIMON FLEXNER (New York) said that a definite relation between lymphocytosis and tumour growth could be worked out. The lymphocytosis may be produced in various ways, but during the lymphocytic period animals are refractory to cancer inoculation. As regards the spontaneous disappearance of tumours in man, it may happen that a local tumour disappears, while metastases in other parts continue to grow. Perhaps we can think of the body being in a different state of immunity in different regions. The disappearance of a growth may be due to a local immunity.

Professor J. G. ADAMI (Liverpool) thought that cancer was due to an alteration of forces in the tissues acting on the cell from without. By appropriate stimulation cells may be induced to take on a habit of growth.

Dr. MURRAY, in reply, commented on various points brought up by different speakers. As regards the cause of cancer, he considered that we were faced with an alteration in the parenchyma of cancer cells, but our knowledge was not sufficient to elucidate its nature.

FRIDAY, JULY 2ND.

Bacteriology of Cerebro-spinal Fever.

Dr. J. A. ARKWRIGHT (London) spoke of the immense amount of work which had been done during the war. He outlined the state of our knowledge in 1914 and the problems which various workers set themselves to solve. The chief interest centres round the classification of the meningococcus. For this purpose morphological, cultural, and serological methods were available. By cultural methods different types were recognisable, but they did not always correspond to the two main groups separated by serological reactions. By methods of agglutination and absorption of agglutinins a number of subgroups could be distinguished, but there was a wide divergence of opinion as to their number and importance. Gordon's division into four types seemed too arbitrary. The serological characteristics bore no relation to the virulence of the organism. As regards carriers, he did not think their isolation was practicable in the present state of our knowledge. The best methods of preparing serum and whether it should be monovalent or polyvalent were still vexed questions. He himself would like to enter a plea for polyvalent serum.

Dr. M. H. GORDON (London) spoke on the researches and observations made in the central military laboratory for cerebro-spinal fever during the war. As regards the pathogenic components of the meningococcus, no certain evidence was found of the presence of an exotoxin, but three intracellular constituents had been identified. The first, a reducing enzyme, does not long survive the death of the coccus. The second, a hæmolytic substance, can be extracted from young cultures by alcohol or acetone. The third is the specific endotoxin of the organism and is chiefly responsible in producing the lesions of cerebro-spinal fever. According to their serological reactions meningococci can be classified into four types. In the cases examined 98 per cent. of the organisms were identified with one or other of these

strains. As a rule, only one type of organism is harboured by patient or carrier. During an epidemic the carrier rate rises considerably. The best way of preventing an outbreak of the disease is to avoid overcrowding. If overcrowding is unavoidable inhalations are effective in temporarily checking the carrier rate. The efficiency of serum treatment depends largely on the amount of anti-endotoxin the serum contains, but the manufacture of a satisfactory serum is still a matter of difficulty. Researches are now being carried out on the standardisation and preparation of antimeningococcic serum.

Dr. T. G. M. HINE (Berkhamsted) analysed 260 reports received from all over the country. These reports included clinical notes and results of treatment. Mortality before serum treatment was about 70 per cent. Mortality from 1914-18 was 60 per cent. in the civil population, but dropped to 35 per cent. in military cases. The latter were treated mainly with Gordon's monotypical serum. The mortality was definitely reduced in cases treated with serum containing anti-endotoxin against the corresponding type of organisms. Serum treatment must be instituted early and in adequate doses to be effective. A pooled serum can be used until the type of meningococcus is identified.

Dr. C. W. PONDER (Maidstone) agreed with Dr. Arkwright as to the uselessness of isolating carriers. An official opinion should be expressed on this point. He examined the bacteriology of the naso-pharynx of non-contacts among the civil population. The meningococcus was found in 41 per cent., and of these 38 per cent. gave sugar and agglutination reactions, and 26 per cent. were positive to absorption tests. These results are higher than those obtained by other workers among contacts. He thought carriers of the meningococcus were comparable to the people who carry pneumococci in their throats and whom no one would dream of isolating.

Dr. A. GARDNER ROBB (Belfast) agreed with Dr. Arkwright that polyvalent sera are of more general use than monovalent sera. Unless he had Dr. Gordon at his elbow to type the organism he would always use the polyvalent. The results with polyvalent sera were as good as those with monovalent sera when figures were carefully compared and the disadvantages and inexperience of early workers remembered. Fallacies might arise in statistics if age-periods are not taken into account. The results in infants were far worse than in people of military age. The death-rate at Belfast, taking all cases, was 27 per cent., and in military cases 12 per cent. Results, taking age-periods into consideration, were about the same in the civil as in the military population.

Dr. J. A. GLOVER (London) showed charts illustrating the effects of overcrowding on the carrier rate and on the outbreak of the disease. After about three weeks of overcrowding the carrier rate rose above 20 per cent., and cases of cerebro-spinal meningitis began to occur. Cultural meningococci are present in the naso-pharynx in normal times, but the proportion of serological types increases enormously in epidemics. As soon as overcrowding was avoided the carrier and incidence rates fell.

Dr. J. C. G. LEDINGHAM (London) spoke of his experience in the East. Detention and isolation of contacts was impracticable, but avoidance of overcrowding and general hygienic measures were effective in checking the disease. The relation of pathogenic bacteria to their homologues needed study. He did not think the use of monovalent serum was practicable.

Dr. W. E. CARNEGIE DICKSON (London) discussed the morbid anatomy of cerebro-spinal meningitis and the paths by which the organism reached the meninges. He produced specimens to show that infection of the ventricles may be earlier and more severe than that of the meninges.

Major W. J. TULLOCH (St. Andrews) answered some of the criticisms made on the work of the central laboratories. He thought too much attention had been called to exceptions in agglutination; 98 per cent. of meningococci can be agglutinated by four typical monovalent sera. Concerning absorption of agglutinins, with the

employment of standard technique no difficulty is found in typing the cocci. Standard technique is of the utmost importance both in culture and agglutination experiments, and no work is of value unless the technique followed is described.

Dr. A. C. E. GRAY (London) confined his remarks to the value of antimeningococcic serum. In his experience the mortality depended on the efficiency of the serum used. Efficient treatment during the first three days really settled the issue, and this must be done with polyvalent serum. He had had no success with monovalent serum when polyvalent serum had failed. The occurrence of serum sickness varied greatly with the serum used. It was not due to differences in dose. Administration of serum should not cease with the disappearance of meningococci in the cerebro-spinal fluid, but should be continued for at least four days.

Dr. J. G. FORBES (London) described a case of meningitis caused by the *Diplococcus crassus*, and gave an account of the characteristics of the organism.

Dr. S. R. SCOTT (London) did not consider that there is any magic number of types of meningococcus. Under conditions of overcrowding there is rapid passage of the organism from one individual to another, and it acquires special virulence.

Dr. ARKWRIGHT replied to various criticisms, and regretted that time did not permit him to enter more fully into the many points of interest that had arisen during the discussion.

Dr. GORDON, in replying, said that in any effort to limit the spread of the meningococcus varying susceptibilities must be taken into account. Recruits were more susceptible than old soldiers. Prophylactic inoculation had not proved satisfactory. Monovalent sera were only undertaken as a preliminary to producing an efficient polyvalent serum.

COMBINED MEETING OF THE SECTIONS OF GYNÆCOLOGY AND ELECTRO-THERAPEUTICS.

THURSDAY, JULY 1ST.

At a combined meeting of these sections, which took place on July 1st, Dr. A. E. BARCLAY (Manchester) took the chair. Owing to the illness of Dr. ROBERT KNOX (London) he called upon Dr. SHILLINGTON SCALES (Cambridge) to read Dr. Knox's paper.

Treatment of Uterine Fibroids.

At the commencement of his paper Dr. Knox stated that it was essential for all cases of uterine fibroids to be examined by a gynaecologist before treatment by X ray was undertaken. He illustrated the benefit of such collaboration by quoting a case in which the opinion of a gynaecologist was refused, with the result that treatment failed to give relief. Later the patient was persuaded to have a second opinion, and it was found that she was suffering from a mucous polypus. Pathological reports on the blood were also of great value.

At the special request of the members present full details of Dr. Knox's technique were then read. In his opinion the following were the contraindications to treatment by X rays or radium: (1) Calcareous degeneration; (2) other forms of degeneration if at all advanced; (3) coexisting malignant disease unless considered inoperable; (4) infection of the uterus; (5) pelvic inflammation; (6) inflammation of organs in the vicinity—e.g., cystitis, appendicitis, &c.; (7) submucous pedunculated fibroids. There were several disadvantages to this line of treatment, such as the long time taken to effect a result, treatment being given at intervals of several months. Moreover, treatment is not invariably successful; the tumour is often reduced in size, but does not disappear. The dangers which exist, such as burns, &c., are easily avoided if the treatment is carried out by an expert. There are, however, great advantages. The treatment is quite painless, there is no interference with the patient's routine of life, no operative shock, and rapid return to health when the hæmorrhage has been arrested. Finally, the author discussed the most suitable types of case for this form of treatment.

Dr. H. WILLIAMSON (London) pointed out the advantages of this combined meeting. Before entering upon the discussion of X ray treatment he thought it was wise to realise the very satisfactory results obtained by operation. Hysterectomy at the present time was one of the most satisfactory operations in the whole of surgery. The operation does not deprive the patient of her ovaries, a very important consideration. In his opinion X ray treatment was contra-indicated in the following ten groups of cases: (1) Where the patient is under 40 years of age; (2) where the tumours can be removed by enucleation, either from abdomen or from vagina; (3) where the fibroid shows evidence of degenerative changes; (4) where the tumour is very large; (5) where there is evidence of inflammatory lesions in the ovaries and tubes; (6) where there is any suspicion of malignancy; (7) where there are severe pressure symptoms in bladder, rectum, &c.; (8) where an ovarian cyst is also present; (9) where the fibroid is complicated by pregnancy; (10) where the patient is gravely anæmic, and the R.B.C. less than 2.5 millions. Finally he stated that the most suitable cases for this form of treatment were those over 40 years of age with a small or moderate-sized tumour, with no evidence of degeneration or malignancy, and where anæmia was not a marked symptom.

Dr. LOUISA MARTINDALE (Brighton) read a report on 118 cases of Fibromyomata treated by her since 1914. Of these, 37 cases were treated by X ray therapy alone, in 5 more hysterectomy was subsequently performed. Her choice of treatment was influenced by the size of the tumour. A very large tumour (i.e., a tumour greater than the size of a six months pregnant uterus) was a distinct contra-indication. Likewise were pedunculated or submucous fibroids. The average number of treatments was seven, but amenorrhœa was obtained after an average of four applications. In 4 cases, a further series of applications was necessary after several months. Finally, the speaker gave a very lucid and concise account of the technique she employed.

Dr. CUTHBERT LOCKYER (London) re-stated the views he had published some years ago: (1) Although acting mainly by destroying the ovaries, X rays have also a destructive influence on the cells of the myoma as evidenced by the shrinkage under treatment, which, when achieved, is too rapid to be explained by inhibited ovarian activity alone. (2) Radium and mesothorium alone are not so suitable as X rays for cases of myoma as no shrinkage of the growth can be expected. (3) X rays combined with radium and mesothorium appear to affect more rapid hæmostasis than X rays alone. (4) The French "cross-fire" combined with intensive technique promises the best results; only by "cross-fire" can topographical difficulties be overcome. (5) Treatment is of no avail in cases of submucous growths. Since then he had somewhat modified his opinion in favour of the use of radium. He did not quite agree with the treatment of young patients by this means, until the regulation of dosage was more exact.

Mr. F. L. PROVIS (London) said that the Röntgen treatment of gynaecological cases should be conducted by the gynaecologist himself. A very careful selection of cases should be made and the diagnosis be absolutely certain. The length of time taken to effect a cure has been quoted as a disadvantage of X ray treatment. This statement, critically examined, does not hold good. Compare the result with that of supravaginal hysterectomy. On an average it takes 18 months to cure by X rays, and menopausal symptoms are not severe. It is questionable whether a patient is in perfect health after a hysterectomy has been performed. Also vaginal hysterectomy induces an early menopause.

Dr. S. G. SCOTT (London) considered that satisfactory results are dependent upon two factors: (1) efficient dosage, (2) careful investigation of cases before treatment. He did not, however, think that any final judgment was at present possible: firstly, because sufficient material was not forthcoming, and secondly, because it is only since the advent of the Coolidge tube that it has been possible to give anything like consistent and effective doses.

Dr. AGNES SAVILL (London) spoke of the advisability of fewer and shorter exposures, to avoid the nausea so frequently found after this form of treatment.

Dr. W. MITCHELL (Bradford) agreed with previous speakers that in papers published on this subject dosage was very inexactly described. He considered that the question of dosage to be given in any individual case should be left to the radiologist.

Dr. SHILLINGTON SCALES agreed that our present methods of treatment were largely empirical, and that it was impossible to lay down any accepted standard as suggested by Dr. Cuthbert Lockyer, owing to the fact that the methods of each skilled worker, whilst arriving at the same result, differed so considerably in detail both as to dosage and filtration. No worker skilled in this form of treatment would consent to carry out unquestioningly a prescription of dosage and technique ordered by a physician or even a gynaecologist whose experience in this respect was not so great as his own. For a gynaecologist of equal practical experience would probably prefer to carry out the treatment himself, and Dr. Cuthbert Lockyer's disclaimer of the necessary knowledge would indicate that this would not often be the case. He was glad Dr. Williamson considered that adverse developments following upon X ray treatment were not necessarily caused by it, and he himself thought that operative treatment was followed by even more frequent ill-results. Our knowledge of the biological effect of X rays was still far from exact, and our methods and apparatus so subject to change and advance that standardisation of our technique was at present impossible.

SECTION OF PHYSIOLOGY AND PHARMACOLOGY.

WEDNESDAY, JUNE 30TH.

Meetings of this section took place on June 30th, July 1st, and July 2nd. On the first of these dates a discussion on

Acidosis in Disease

was opened by Professor F. GOWLAND HOPKINS, F.R.S., the President of the section. Professor Hopkins first emphasised the need for the removal of the ambiguity which is associated with the use of the term "acidosis." He then went on to describe the regulation of the reaction of the tissues, pointing out that the blood constitutes a kind of mechanism for the coarse adjustment of the concentration of hydrogen ions, the more exact regulation being brought about by the kidneys and respiratory centre. The disturbance of reaction produced by exposure to anoxæmic conditions as described by Haldane and his co-workers, and the appropriateness of the term "alkalosis" to the description of the symptoms was discussed. Professor Hopkins concluded his speech by referring to the riddle presented by the production of the acetone bodies when carbohydrate metabolism is arrested or disturbed.

Professor W. M. BAYLISS, F.R.S., suggested that there was little use for the word "acidosis" in the sense of an actual increase of concentration of hydrogen ions, as such an effect was rarely produced in life. The symptoms of reduced alkali reserve were probably not due to excess of hydrogen ions. The speaker quoted experiments which showed that the plasma proteins took no part in the regulation of the reaction of the blood.

Further emphasis was placed on the desirability for a clearer definition and application of the nomenclature by Dr. H. H. DALE, F.R.S.

Professor T. H. MILROY pointed out that the acetone bodies were very strong acids, and in this way accounted for the marked fall of alkali reserve in conditions of ketosis. He discussed the increased output of ammonia and the utilisation of alkali administered by the mouth in these conditions.

Dr. E. P. POULTON pointed out a source of fallacy in Van Slyke's method for estimating the alkali reserve of blood on account of the variation of the carbon-dioxide combining power of the plasma with the carbon-dioxide content of the blood from which it was separated. He then referred to a number of cases in which the actual reaction of the blood had been measured directly,

and pointed out the divergence between the results of direct and indirect estimations of reaction.

Mr. T. R. PARSONS gave an account of the reaction-regulating mechanism of the normal blood. He pointed out that the "buffer" value of blood was greater than that of solutions of sodium bicarbonate, and ascribed the difference to the properties of hæmoglobin.

Dr. P. J. CAMMIDGE mentioned experiments which suggested that the state of the liver played an important part in ketosis, and hoped that in any new nomenclature care would be taken to establish terms which would be useful in describing the results of future developments of our knowledge.

Dr. MACKENZIE WALLIS emphasised the importance of renal function. He regarded diabetic coma as being produced by a sudden retention of acetone bodies rather than by a sudden increase in the amount of their production. He regarded the pancreas as the seat of formation of a catalyst necessary for the formation of ethereal sulphates, since, in the absence of pancreatic juice entering the intestine, there was little or no ethereal sulphate in the urine.

Dr. W. D. WILKINS called attention to the fact that ketosis was associated with acute mental disease in a large proportion of cases. There seemed to be a relation between the presence of acetonæmia and mental symptoms, since mental disturbances were prominent in uræmia and diabetic coma.

Dr. E. GRACE SHERWOOD gave an account of the occurrence of acetonuria in children suffering from infective disorders.

Mr. S. W. COLE detailed his experiences in the treatment of post-operative ketosis by the administration of glucose and pancreatin. Discussing the ketosis of pregnancy associated with vomiting, he mentioned that it seemed to be due in many cases to a defective action of the pancreas, and in certain cases at least was amenable to the same treatment.

Dr. A. F. MARTIN asked whether there was any connexion between the action of bacterial toxins and the production of acetone bodies.

In concluding the discussion Professor HOPKINS emphasised the value of carefully collected data from clinical experience in the investigation of the cause of the disorder of the metabolism of carbohydrates which led to the production of the acetone bodies.

THURSDAY, JULY 1ST.

Professor J. N. LANGLEY, F.R.S., opened a discussion on the

Treatment of Denervated Muscle and the "Disuse" Theory.

Professor Langley proceeded to point out that the "disuse" theory of muscular atrophy after nerve section, according to which the degeneration of the muscular tissue is directly caused by inactivity, still remains the dominant one. The method adopted for the treatment of cases of muscular denervation will depend upon the theory held as to the nature and causes of the symptoms observed. In order to investigate the effects of the recognised forms of treatment—electrical stimulation, passive movement, and massage—he had carried out experiments on rabbits in which the sciatic nerve had been cut on both sides and the degenerated muscles on one side were subjected to treatment, while those on the other served as a standard. The criterion used for determining the condition of the muscles was their comparative weight. It was found that three weeks' treatment, either by electrical stimulation with condenser shocks or by passive movement or by massage, produced no very decided beneficial effect in delaying or in reducing the extent of the muscular degeneration. Professor Langley also referred to the similar experiments of Hartman, Blatz, and Kilborn, in which the capability of performing work was used as an extra criterion of the condition of the muscle, and in which the periods of treatment were much longer, but which led their authors to the same conclusion. In view of the doubt that these methods of treatment directly benefit the denervated muscle, it was suggested that the beneficial effects claimed by clinicians were due to the incidental circumstances involved in the treatment—namely, care in diet, a

general hopeful disposition of the patient, and suitable safeguards against further injury. The condition of the nerve cells during regeneration of their axons was another important factor in the recovery, as suitable stimulation was known to produce a more rapid regeneration of the severed nerve fibres. In conclusion, Professor Langley pointed out that the most cogent argument against the commonly accepted "disuse" theory was the observation that a denervated muscle was in a state, not of rest, but of perpetual rhythmic fibrillar contraction.

Dr. E. P. CUMBERBATCH said that the conclusion that electricity is of little or no value in the treatment of denervated muscle was opposed to the opinions of those who had had long experience in the electrical treatment of paralysis. He described a case of infantile paralysis of both lower limbs in which a considerable return of voluntary power resulted from treatment with the sinusoidal alternating current. This does not produce muscular contractions, but probably acts by stimulation of the severed neurones by afferent impulses from the skin. After voluntary power is regained currents which cause contraction may be used provided their application is not carried to the point of producing fatigue. The speaker also referred to the need for maintaining a proper temperature in the treated muscles, as cold greatly retards recovery.

Dr. W. J. TURRELL pointed out that Professor Langley's experiments applied to the period of three weeks immediately following the nerve section, which is a period concerning which electro-therapists have little experience, as electrical treatment is usually begun at a later stage. It is only after nerve irritation has ceased that electrical stimulation should be applied. The requisite warmth of the affected part can often be suitably maintained by means of the galvanic current.

Dr. F. HERNAMAN-JOHNSON recommended the use of the faradic current for the production of long-continued contractions in a muscle in which voluntary power is beginning to return. He pointed out the need for avoiding fatigue in this method of treatment.

Dr. E. D. ADRIAN proposed that if electricity merely acts as a suggestive remedy it might be replaced by something simpler, cheaper, and more impressive; but he considered that electricity does produce direct effects. The general view is that electrical treatment usually results in at least a certain amount of contraction, and this might be of benefit in freeing the muscular fibres from adhesions produced by the overgrowth of connective tissue, the muscle thereby being kept in good mechanical condition.

Dr. NOEL BURKE would have expected that the treatment applied by Professor Langley during the first three weeks of degeneration would have been positively harmful. Nothing can be done to prevent the initial degeneration of the muscle after section of its nerve. In these early stages a non-contracting current is indicated which acts by producing chemical and reflex effects. It is only in the recovery stages that contracting currents should be used together with educative treatment.

Dr. F. ROBERTS called attention to the danger of overstretching a denervated muscle. He had observed that among the denervated leg muscles of the rabbit those which were stretched in the normal position of the limb suffered the greater amount of degeneration. This factor may enter into Professor Langley's experiments, as the beneficial effects of the contractions in some muscles might be counteracted by the stretching to which they were submitted when their antagonists were stimulated. He regarded the psychological effect of electrical treatment as being very great.

Professor LANGLEY, in replying, maintained that there was no break in the series of changes occurring in a denervated muscle from the second day up to a year. The fibrillation gradually dies out as the atrophy sets in.

FRIDAY, JULY 2ND.

Professor W. E. DIXON, F.R.S., opened a discussion on *Quinine and its Related Alkaloids in Pharmacology and Therapeutics.*

Professor Dixon briefly referred to the chemistry of quinine and pointed out the relationships between

hydroquinine, hydrocupreine, equinine, cinchonine, and similar derivatives to the mother substance. He then explained that the characteristic action of quinine on living tissues consisted in a reduction of general metabolism, and illustrated the relative strengths of the quinine derivatives in this respect by their action on protozoa and on bacteria, and by their efficacy in producing paralysis of sensory nerve-endings in the cornea. The striking feature of the quinine derivatives was the relatively small concentration necessary to produce marked effects.

Professor W. RAMSDEN recounted experiments showing that the concentration of quinine in red corpuscles is about one-third of that in the surrounding serum. The ratio of concentration of quinine in urine to that in the blood may rise to a value of about 200, but this secretory activity of the kidney seems not to involve any damage to the organ, as it is unaccompanied by albuminuria.

Major H. W. ACTON related the experience he had had with cinchona alkaloids other than quinine in the treatment of malaria. Both cinchonidine and quinidine gave results of value.

Sir ARCHIBALD GARROD discussed the relation of quinine to the onset of blackwater fever, and while he believed that in certain cases the drug was a contributory factor, in many others the disorder seems to have been induced by exposure to cold or by active violent muscular exertion.

Dr. T. S. HELE recorded his experiments on the rate of excretion of quinine in the normal subject and in patients suffering from blackwater fever. He found that they were markedly different provided a sufficient volume of urine was produced. He drew a comparison between the excretion of quinine and that of ethereal sulphate which followed the administration of poisonous ring compounds to animals.

Lieutenant-Colonel Sir LEONARD ROGERS recommended the treatment of severe cases by intravenous injection of quinine and of others by intramuscular injection of cinchonine acid hydrochloride.

Dr. M. NIERENSTEIN suggested that blackwater fever might be produced by a substance—hæmoquinic acid—which is formed from quinine in the body. This acid is known to have hæmolytic properties.

Dr. J. C. MCWALTER stated that the treatment and prophylaxis of malaria by quinine had been a complete failure.

Dr. C. M. WENYON said that very little new knowledge on the subject of quinine administration had been obtained during the war. The mode of action of quinine was very uncertain, but useful light might be shed on the problem if the plasmodial infection in birds were further studied. It would be useful to know the reason why quinine produces so little effect in this case.

Professor J. A. GUNN had experimented with the alkaloids harmaline and harmine, and had obtained encouraging results in cases of relapsing malaria.

Dr. DALE pointed out that the lack of action of quinine in the case of avian malaria might be due to some influence of the host. He had proved that the same strain of *Entamoeba histolytica* was susceptible to the action of emetine in the human subject, but not when transferred to a kitten. He further remarked that if the total alkaloids of cinchona were to be utilised this would have a very profound influence on the present policy of cinchona planting.

Colonel R. MCCARRISON suggested that in cases where the blood pressure was dangerously low this could be counteracted by the injection of adrenalin together with the alkaloid.

Dr. A. G. BODMAN recommended the injection of saline solution as well as the alkaloid in order to assist in bringing the drug into effective contact with the parasites in blocked capillaries.

In replying, Professor DIXON mentioned the harmful effects resulting from the intramuscular injection of strong solutions of quinine.

Demonstrations.

On the afternoon of Friday, July 2nd, the following demonstrations were given in the Physiological Laboratory.

Dr. C. SHEARER: The heat evolved during the growth of bacteria. The cultures were grown in Dewar flasks and changes in temperature measured thermoelectrically.

Mrs. E. W. PARSONS: Constant temperature centrifuge (used in the study of gaseous equilibria in blood) and large centrifuge.

Mrs. D. THACKER and Dr. E. D. ADRIAN: Capillary electro-meter recording the electrical variations in the frog's heart, and other electrical measurements.

Mr. W. HARTREE: Thermopiles for the registration of very small changes of temperature, particularly those occurring in muscular contractions.

Mr. W. M. COLEMAN: The voluntary control of the pulse-rate.

Mr. T. R. PARSONS: Apparatus for determining the hydrogen-ion concentration of blood and other body fluids by the electrometric method.

Dr. E. J. COHN: The preparation of solutions of pure hæmoglobin by dialysis at 0° C.

Dr. H. HARTRIDGE: (1) Colourless safe light for photography; (2) the estimation of carbon monoxide in blood; (3) methods for microscopic illumination.

Mr. G. S. ADAIR: Osmometers. The determination of the osmotic pressure of hæmoglobin.

Mr. J. E. BARCROFT: Air-tight glass room for experiments on respiration.

Dr. FF. ROBERTS and Dr. E. P. POULTON: Apparatus used in determining the dissociation curve of blood, and in obtaining and analysing alveolar air.

Professor LANGLEY: The fibrillation of denervated muscle (to illustrate his opening speech of the morning): Slides showing the absence of central degeneration in nerves tied so as to divide the axis cylinders and medulla, but not the neurilemmal sheaths.

Professor C. A. LOVAT EVANS and Dr. H. H. DALE: A dialysis-indicator method for determining the hydrogen-ion concentration of blood.

Dr. F. H. A. MARSHALL and Mr. J. HAMMOND: Histological preparations and dissections illustrating points in the physiology of reproduction.

Dr. T. LEWIS and Dr. FEIL: An auricular myograph.

Professor and Mrs. E. MELLANBY: Accessory food factors. Dogs exhibiting the effects of deficient diets were shown, and also histological specimens and X ray photographs.

SECTION OF TROPICAL MEDICINE.

WEDNESDAY, JUNE 30TH.

Problems of Filariasis.

This section opened on June 30th, with Professor G. H. F. NUTTALL, M.D., F.R.S., as President, when

Professor J. W. W. STEPHENS read a paper on the Problems of Filariasis, in which he drew attention to the conflicting statements as to the relationship of *Filaria bancrofti* to lymphatic diseases and the erroneous conclusions drawn from the failure to discover microfilariae in the blood of cases of elephantiasis—a failure due to the death of the adult filaria previous to or following on the stage of the development of elephantiasis. He exhibited tables of figures giving the proportion of population examined and the percentage of those examined and found to be infected by microfilariae in Amoy (China) by Manson in 1883, in Fiji by Manson-Bahr in 1912, and in Cochin China by Cruickshank and Wright in 1914, and in the case of Manson-Bahr's statistics (see table) the age-periods concerned.

	Population examined.	Percentage infected.		Population examined.	Percentage infected.
0-10	72	1.4	41-50	83	45.7
10-20	222	15.7	51-60	58	44.8
21-30	212	37.7	61-70	39	41.0
31-40	118	47.5			

Tables were also displayed, giving the microfilarial rate among the natives of Fiji and Cochin China in two groups: (1) those showing signs of lymphatic disease; (2) those without evidence of such condition. Manson's data derived from natives of Amoy (China), 1883, agreed with those of Manson-Bahr for Fiji (1912), in that these observers found that the microfilarial rate was greater in group (1) than in group (2), although Manson's data derived from specimens at a later date (1907) than his

original observations and the results obtained by Cruickshank proved to be directly opposite. Microfilarial rates were also compared among those suffering from elephantiasis and those not so suffering; observations of Manson in 1883 and Tribondeau showed that those infected with microfilariae were more numerous among the elephantiasis than among the non-elephantiasis group, whereas Manson's later figures (1907) and Cruickshank's (1914) from Cochin China showed the reverse to be the case. Comparisons of infection by microfilaria, elephantiasis and lymphatic abscess rates were further provided by tables, and also of the varying rate of infection in different countries. Manson-Bahr in Fiji (1912) found 27.1 per cent., Cruickshank in Cochin China (1914) 20.9 per cent. of population infected. Furthermore, enlargement of lymphatic trunks proved to be nearly ten times as common in Fiji as in Cochin China, and of the lymphatic glands twice as common in Fiji as in Cochin China. Results of the work of various observers seemed to show that the region of the body affected by elephantiasis varied according to the particular country, and much investigation was required to explain this peculiarity.

Dr. P. MANSON-BAHR then read a joint paper by Dr. G. C. LOW and himself on

The rôle of Filaria bancrofti in the Production of Lymphatic Obstruction, and a Consideration of Elephantiasis from the Pathological Standpoint,

in which he discussed the discrepancies of different observers. He attributed them partly to the want of standardisation of methods adopted in securing specimens of blood—a personal factor, and partly to the uncertainty of clinical details as to what constituted glandular enlargement, and the standard of enlargement to be recognised as due to filarial disease, particularly as it was the exception to find the native, accustomed to going about barefoot, and therefore readily subject to septic infection, without slight degrees of glandular enlargement. The question of degree of enlargement involving the lymphatic trunk and what should be regarded as a thickened condition due to filarial infection was one requiring definition. *Filaria bancrofti*, he maintained, had a different habitat in the body which varied according to geographical distribution; in China and India the adult worm inhabited the lymphatic trunks, whereas in the Pacific the lymphatic glands, and especially the epitrochlear gland, were the most usual seat. A further important feature affecting different observers' results and favouring the possibility of erroneous conclusions was to be found in the fact that in the East microfilariae were nocturnal in their appearance, but in the Pacific they were quite irregular in their periodicity. The degree of pathogenicity of *F. bancrofti* was governed by three fundamental factors. (1) Zoological, according to whether there were dead or living filariae in the lymphatic glands or trunks, the dead acting as a mechanical irritant. Provided embryos could get free passage through the lymphatic vessels they caused no obstructive disturbance and were, therefore, not pathogenic, and their host might remain in perfect health for some considerable time and only at a later date show evidence of lymphatic obstruction. (2) Pathological. With the presence of *F. bancrofti* in a lymph channel, narrowing of the lumen of the vessel might develop as the result of proliferation of the lining endothelium, and subsequent occlusion be produced. This resulted in obstruction to the free passage of microfilariae along the lymph vessels to the glands, especially those distal to the obstruction. They laid stress in particular on fibrosis of the lymphatic glands as a pathological feature to which little attention had been drawn, a change accompanied by giant cell formation and eosinophil production, and probably due to helminthic toxins causing inflammatory disturbances, which may be widely scattered and generalised in their effects on the glands. As a result of obstruction to the lymph channels with lymphangitis and consequent lymph stasis, the embryos were unable to survive for long in the stagnant lymph stream and would consequently disappear from the blood circulation, the dead microfilariae being found only in the

lymph capillaries and glands. The parasitic cause became defunct but its obstructive effect remained, and after repeated infestation resulted in the gradual development of elephantiasis. In the diagnosis of tropical elephantiasis the importance of the disappearance of the microfilariae from the blood-stream required to be borne in mind, as well as the possibility of elephantoid conditions arising from such other causes as septic lymphangitis, from the absorption of irritant poisons, as in a case quoted due to the effect of chrysarobin; also as the result of lymphatic fibrosis following on such infections as spirochaetosis.

They emphasised the unreliability of statistics from different sources, the anomalies of which, due to the various factors already mentioned, could be explained and corrected by the proper study of the pathology of the disease. He summarised such study as proving, firstly, that *F. bancrofti* was a parasite of, as elephantiasis was a disease of, tropical and sub-tropical countries; secondly, that the maximum rate of microfilarial infestation corresponded with that of elephantiasis; thirdly, that the filarial disease rate was double that of the concomitant microfilarial invasion of the blood, and consequently the embryo rate could not be regarded as a true measure of the blood infection in any particular population.

Major E. BLACK introduced his remarks with a reference to his unique experience and early association with the work of Bancroft himself. He agreed with Dr. Manson-Bahr as to the unreliability of statistics bearing on microfilarial blood infection in that microfilariae might be found in the glands when not in the blood, and therefore their absence from the blood-stream was no measure of the degree of infection. He also pointed out that in Brazil and Western Australia microfilariae could be found in the blood of almost every person examined without there being any evidence of impaired health, elephantiasis, or enlargement of the glands, and that many of the cases originally examined by Bancroft 40 years ago, and found to be infected, still remained in good health. The state of our knowledge of filariasis was at present far from complete, and explanations were needed as to the night rises of temperature which might possibly be attributed to the presence of microfilariae in large numbers in the blood. He conjectured that the solution of the problem of toxicity might yet be found and differentiated on the same lines as the dependence of bacteria for their toxicity on the protein of their cell bodies, and that so the toxicity of filariae might vary according to the composition of their particular proteins. The susceptibility of monkeys to filariasis might also assist in providing a solution.

Discussion.

Surgeon-Captain P. W. BASSETT-SMITH, R.N., considered that much depended on the technique of work employed and on the clinical and pathological conditions in the provision of reliable data. Absence of the effects of a prevalence of microfilariae in the blood formed a curious feature of filarial disease. A degree of eosinophilia ranging from 50 to 20 per cent. pointed to toxic influences. The presence of microfilariae in the blood was very little affected by intravenous remedies of arsenic or antimony, which did not appear to exert any influence on the amount of infection. The inoculation of rabbits and guinea-pigs with microfilariae so far had shown no ill-effects.

Dr. D. E. ANDERSON suggested that the rise of temperature might be due to the quantity of food causing greater activity of filariae in the evening. In regard to the prevalence of elephantiasis, he thought the number of cases found in St. Kitts and Madagascar was much less than expected.

General P. HEHIR, A.M.S., alluded to the location of filariae in the generative system and bladder as being common in Calcutta, and, with reference to chyluria, mentioned the first discovery of microfilariae in the urine by Timothy Lewis in 1871.

Dr. W. F. LAW, quoting from 25 years' experience in British Guiana, had never seen any marked epitrochlear gland enlargement, and referred to the work of Dr. Wise,

who associated the death of the parent worm with lymphangitis due particularly to streptococcal infection.

Dr. B. SPEARMAN asked if Dr. Manson-Bahr had experienced a heavier incidence of filarial disease in men than women. His experience in Uganda had shown that out of a total of 10-20 per cent. infection of the whole of the native population all had been men, and that the disease was very rare in women. He had never found any epitrochlear gland enlargement, or elephantiasis of the upper extremity, breast, or arm.

In replying to various points raised in the discussion, the opener, Professor STEPHENS, observed that the object of his paper was not so much to bring forward the relationship of *F. bancrofti* to filarial disease as to put on record facts already known, and to draw attention to discrepancies which occurred among these records.

Dr. MANSON-BAHR claimed that the investigation of filarial disease should include a complete survey of all tropical countries. There were many statistics available which were the result of anything but exact observation and reliable material. A close observance of accurate and systematic technique was essential, and a new basis of work was much needed to get rid of erroneous results. Among natives it was impossible to attain to anything like accuracy as to the age-periods, and his tables of the age incidence of filariasis were purely approximate. In Fiji he found that more men than women were infected, due, no doubt, to the different habits of the two sexes, the former working in the fields and therefore more exposed to infection conveyed by the bites of mosquitoes, while the women stayed at home.

In blood-cell changes in filariasis he included polymorphocytosis and eosinophilia, but he did not pay too much attention to the latter, as in Fiji as much as 13 per cent. eosinophilia was very common among the majority of natives. Enlargement of the epitrochlear gland was also common in the Pacific Islands, due largely to the fact that the carrier of infection, *S. pseudo-scutellaris*, in Fiji shelters among the yam plantations and bites during the day, attacking chiefly the exposed hands of the men labourers. Consequently the *F. bancrofti* would be found to vary its habitat, and similarly the distribution of elephantiasis in the body would vary according to the habits of the natives and the particular mosquito acting as carrier of the filarial infection. In other parts of the world, *Culex* was the carrier, and, biting at night, infected other parts of the body, especially the legs, rather than the arms.

Dr. Low, also replying, emphasised the importance of obtaining measured quantities of blood and at stated periods, for securing an accurate estimate of the microfilarial rate. Cases of elephantiasis, chyluria, and lymphangitis seldom showed microfilariae in the blood, from the fact, especially in elephantiasis, that the *F. bancrofti* was long dead. For the embryo-rate two classes had to be considered, those with filarial disease and those without filarial disease. He regarded the great difficulties of work at night as providing possible sources of error. To obtain a correct estimate of the local rate of infection it was important to examine only indigenous natives and to avoid inclusion of those who had migrated from other parts. Unless such migration from uninfected areas was discounted, it would lead to considerable inaccuracies when attempting to arrive at reliable conclusions based on the blood examinations of natives in any given locality. In Grenada he was told there was no filarial disease, and in examining for the embryo-rate, out of 400 natives not one showed microfilariae. Dr. Kocher had examined as many as 2000 without finding any embryos. In Barbados there was more evidence of infection. In St. Kitts, where there was an enormous degree of filarial disease, the microfilarial rate was 30 per cent. The rate of infection varied much with evidence of filarial disease, as in the case of elephantiasis already mentioned, the absence of microfilariae from the blood was due to the death of the parent worm long previously.

With reference to the pathogenicity of the filaria, Dr. Low gave instances of the presence of microfilariae in the blood, followed possibly in five years by the develop-

ment of elephantiasis, with a disappearance of embryos from the circulation. Fresh re-infection would account for the appearance of microfilariae in the blood of some cases of elephantiasis. He was well acquainted with the valuable work of Dr. Wise in British Guiana, and remarked on the association between filarial abscesses and the death of the parent worm, which might be due to coccal infection resulting in septic lymphangitis and septicæmia. There was possibly a racial susceptibility to filarial infection in British Guiana, and he regarded the Portuguese and Barbados negroes as more liable to infection than the pure white European, who, however, might, after long residence, become infected. This was probably rather a question of antifilarial prophylaxis, protection by the use of mosquito-nets.

During the course of the afternoon demonstrations Dr. MANSON-BAHR, in illustration of his paper, exhibited a number of interesting microscopical slides showing the pathological changes of filarial disease—e.g., obstruction to the lymphatic vessels, glandular fibrosis, and calcification of the filaria.

Lieutenant-Colonel R. MCCARRISON, I.M.S., read a paper on

Dietetic Deficiency and Endocrine Activity, with Special Reference to Deficiency Edemas,

in which he described the results of experiments on pigeons, guinea-pigs, and monkeys, produced by feeding these animals on six classes of deficient dietaries: (1) deficient in all three classes of vitamins and in suitable protein, but rich in carbohydrates; (2) deficient in B and C vitamins, and rich in carbohydrates and fats; (3) deficient in B vitamin, but rich in carbohydrates and fats; (4) deficient in A and B vitamins; (5) B vitamin only lacking; (6) C vitamin deficient. He attributed the effects of these dietaries on the endocrine organs to the action in varying combination of, firstly, deficiency of vitamins; secondly, imperfect balance of the proximate principles of the food; and thirdly, the chance occurrence of pathogenic agents in the body. As the result of dietetic deficiencies, all endocrine organs except the adrenals and pituitary body, which underwent enlargement, suffered varying degrees of atrophy and lowering in functional capacity. Colonel McCarrison described the alteration which took place, following on the use of the various deficient diets in the different animals experimented on, and displayed diagrammatic charts showing the relative changes produced in the endocrine organs, the thyroid and parathyroid glands, the gonads, the pancreas, thymus, spleen, pituitary body, and adrenal glands.

The effects, such as atrophy and hæmorrhagic enlargement, differed according to the species of animal, the character of the deficient diet, and the particular organ, not all the animals responding in the same degree when fed on the same diet. The adrenal glands, the most susceptible of all the endocrine organs to dietetic defects, were found to become enlarged as the result of all six classes of deficient dietaries and also in consequence of starvation. But the character of the enlargement varied according to the class of diet, both histologically and as regards adrenalin content—e.g., a scorbutic diet in guinea-pigs produced hæmorrhagic infiltration of the cortex, associated with a great reduction of the adrenalin content, whereas in pigeons autoclaved rice and butter gave rise to marked hæmorrhagic infiltration of the medulla and, as a rule, a low adrenalin content. With food deficient in vitamins and suitable protein and rich in carbohydrate, but well balanced with regard to proximate principles, the enlargement of the adrenals was less marked and the adrenalin content lower than when this balance was wanting, in the case of pigeons and monkeys. The quality of the food, therefore, governed the amount of adrenalin content, as also did concurrent infections. Edema, usually hydropericardium, was often associated with enlargement of the adrenals, but did not occur in the absence of a corresponding increase of adrenalin content. It was found that the addition of fresh butter to a dietary of autoclaved rice lowered the incidence of oedema in pigeons, and appeared to afford complete protection up

to the thirty-sixth day of the experiment, after which, however, the butter gave no protection against the occurrence of wet polyneuritis, although some of the pigeons, 19 out of 29, had already developed dry polyneuritis.

The lowered incidence of oedema was associated with a lowered adrenalin content, yet an increase in weight of the glands occurred. The limitation of protection against wet polyneuritis to 36 days was attributed to the development of pathological changes in the digestive organs resulting from deficient dietaries and possibly from an inhibition of the assimilation of substances on which protection against oedema was dependent. Butter was also found to vary in its capacity to protect against oedema in pigeons fed on autoclaved rice, due probably to a difference in the lipochrome content of the butter, according to the particular fodder on which the cows providing the milk for the butter were fed. It was therefore suggested that the hypothetical "anti-oedema" substance might be of the nature of lipochromes.

Summarising the chief points of the results of his experiments Colonel McCarrison again drew attention to the changes in the adrenals, the character of whose enlargement varied with that of the dietetic deficiency. The adrenalin content also varied according to the diet, being in excess when food was deficient in vitamins and protein but rich in starch, below normal when the diet was scorbutic and when concurrent infections were associated with dietetic defects. He pointed out the important bearing of his observations on the causation of deficiency oedemas in the human subject. He regarded it as probable that interference with the normal excretion of urine by an excess of adrenalin reaching the kidneys favoured the retention of fluid in the tissues. As pointing in this direction he quoted human beri-beri with its associated adrenal enlargement and high adrenalin content and small output of urine, and alluded to the inhibition of the urinary flow by intravenous injection of an excess of adrenalin and the retention of NaCl caused thereby in the tissues. He maintained that as a channel of communication had been shown to exist between the kidneys and adrenals, the product of the glands might reach the kidneys without alteration in the general circulation, and thus control the excretion of urine. There followed, in consequence, the important fact that adrenalin was, in its turn, controlled by the quality of the food.

Additional factors doubtless played a part in the causation of oedema, such as impaired endothelial function, changes in vascular permeability, impaired metabolism of proteins and lipoids, and chemical changes in the tissues—all attributable to disturbed endocrine function and altered metabolism following on deprivation of vitamins and malnutrition.

In reply to points raised in the discussion which followed, by Dr. ANDERSON, Surgeon-Captain BASSETT-SMITH, Dr. LOW, Dr. MANSON-BAHR, and General HEHIR, Colonel MCCARRISON said that it was not known what particular deficiency of diet caused such specific effect as enlargement of the adrenals. He considered that the fatty degeneration of the adrenal cortex accounted for alterations in adrenalin content, but it was not known whether the cortical changes were toxic in origin. As regarded the condition of the liver following on use of deficient dietaries there was no great amount of atrophy measurable by alteration in weight; histologically there was congestion of the hepatic capillaries and degeneration of the liver cells. Depression of cellular function was the foundation of diseases of dietetic deficiency.

With reference to the causation of war oedema he was of opinion that its production was due to the mixed effect of a dietetic deficiency of vitamins and lack of protein, assisted probably by pathogenic agencies within the body. As to the influence of extra work in the presence of dietetic deficiency, he had found that the most active animals suffered earliest—as in the case of pigeons with polyneuritis—and so with dogs, who developed rickets earlier than other less active animals. He attributed this early response to the greater call on metabolism brought about by greater muscular activity

There was an exhibition of specimens in illustration of Colonel McCarrison's paper in the Pathological Museum.

Stibenyl in the Treatment of Trypanosomiasis.

Dr. MANSON-BAHR read the paper on his recent experiences with intravenous injection of stibenyl (acetyl-p-amino-phenyl stibiate of sodium) in the treatment of trypanosomiasis and kala-azar, which appears in our original columns.

Dr. ANDREW BALFOUR referred to the race for favour between emetine and antimony in the treatment of tropical disease, and sought information as to how antimony acted, whether the beneficial results were due to a direct parasitocidal or a more general action.

Colonel S. L. CUMMINS, A.M.S., alluded to the effect of antimony on pathogenic yeast, and inquired as to the possibility of its action directly on the organisms or on the tissues surrounding them.

Dr. MANSON-BAHR, in his reply, stated that emetine was not poisonous to *Entamoeba histolytica* outside the body and that its beneficial action in tropical abscess might be attributed possibly to the effusion of serum which occurred into the abscess cavity, and thus killed the entamoeba. He thought it probable that antimony compounds varied in their action according to the particular parasite, and that each kind of parasite required a special antimony preparation, as instanced in the case of bilharziasis, which responded to antimony tartrate, but not to stibenyl, whereas in trypanosomiasis antimony tartrate was badly tolerated and stibenyl promised excellent results.

Demonstrations.

The Section provided demonstrations during the afternoon sessions of June 30th and July 1st, which included—

1. Parasitic Worms, by Dr. R. T. LEIPER.
2. Exhibition of all known species of Tsetse Flies, including a consideration of their morphology and bionomics, by Professor R. NEWSTEAD.
3. Paintings illustrating the treatment of Leprosy by Chaulmoogra Oil, Soya Bean, Sodium Gynocardate, and Sodium Morrhuate, and the striking effect of the latter two drugs, by Sir LEONARD ROGERS.
4. The treatment of Bilharziasis by Intravenous Injections of Antimony Tartrate, by Dr. J. B. CHRISTOPHERSON. Two points were emphasised: (1) That antimony (pot.) tartrate given intravenously (a) kills the adult bilharzia worms, (b) kills and sterilises and arrests the ova which the worms have deposited, by killing the myracidium within the ovum; (2) that the operation of intravenous injection of antimony tartrate is a simple one, and is capable of being carried out as out-patient procedure on a large scale.
5. Microscopic slides illustrating Elephantiasis, and showing the histological changes in filarial obstruction of the lymphatic vessels, dead and calcified specimens of *F. bancrofti*, by Dr. MANSON-BAHR.
6. Malignant Malaria, by Dr. J. F. GASKELL, including preserved brain sections from a case of cerebral malaria which showed extensive punctate hæmorrhages; also microscopical slides and drawings of heart muscle and spleen showing degenerative changes and fibrous tissue-formation respectively, and in them the suggested nidus of the resting parasite. Slides and drawings were also exhibited of the development of the male and female crescents, and of the phases of the ring, schizont, and rosette formation coexisting in the same case, together with clinical details of a fatal case terminating suddenly from acute toxic effects, and of proportional counts of the number of parasites in the circulation per c.mm. exhibiting a fall coincident with intravenous administration of quinine.
7. Early stages in the life-history of *Ascaris lumbricoides* were demonstrated by Colonel F. H. STEWART, I.M.S., who explained the migration of the larva from the bowel via the portal circulation into the liver, thence by the venous circulation to the right heart, eventually through the pulmonary capillaries to reach the pulmonary alveoli and to regain the alimentary tract by way of the bronchial passages, trachea, pharynx, and oesophagus—a cycle

of events occupying a period of about ten days—at the expiration of which the larvæ appeared in the fæces. Microscopical sections were shown displaying the larvæ and the changes produced by them in the pulmonary alveoli and liver. The details of his work and experiments on animals were recently described in a paper read at a meeting of the Royal Society of Tropical Medicine and Hygiene.

8. Specimens and illustrations of various parasites and carriers of diseases affecting man and animals were exhibited by Professor NUTTALL, who also showed a collection of portraits of those who have advanced the subject of parasitology.

9. Demonstration of the use of the Mobile Laboratory for Malaria Inquiries in England by Lieutenant-Colonel S. P. JAMES, of the Ministry of Health.

10. A lecture, illustrated by lantern slides, on "Serbia under Typhus in 1915: the Story of a Great Epidemic and its Arrest," was given by Dr. W. HUNTER

EXHIBITION OF SURGICAL AND ELECTRICAL APPLIANCES, DRUGS, AND FOODS.

II. *Drugs, including Antiseptics—Continued from p. 140.*

The pharmaceutical products shown by the Anglo-French Drug Co., Ltd., of 238A, Gray's Inn-road, London, W.C., claimed much attention. These were chiefly of French origin, and included the arsenical compounds, galyol, novarsenobenzol, and glucarsenol, a glucose solution of the latter with analgesics. The visitors' attention was also drawn to the employment of stannoxyl—metallic tin and pure oxide—in staphylococcus infections, and a preparation called "elixir bromo-valerianate," odourless and tasteless, with or without strontium bromide is worthy of notice as an advance in pharmaceutical preparation. Modern organo-therapeutic products were well represented by the G. W. Carnrick Co., of New York, and 6, Northumberland-avenue, London, W.C. Hormotone, for example, is described as a combination of those hormones of internal secretion, which coöperate in maintaining the dynamic force of the organism, the sthenic as against the asthenic condition. Tryposegen, an extract of the pancreas, claiming to be useful in completing sugar metabolism in diabetic cases, was another item, and as well were shown specimens of various desiccated extracts, anterior pituitary, suprarenal, lymph, testicular, and so forth. The exhibit of Messrs. Howards and Sons, Limited, of Ilford and Stratford, was interesting. First in the list we may place agotan (2 phenylquinoline, 4 carboxylic acid) described as extraordinarily efficacious in eliminating uric acid from the system. Then they showed the hydrogenated derivatives of the cinchona alkaloids (hydroquinine, amongst others), which have been found by some to exhibit therapeutical advantages over their parent, the classic quinine of the materia medica, in malarial treatment. There was included the standard ether of this firm kept closely to physical constants, a proceeding clearly desirable in anæsthetic work.

It is noteworthy that the element sulphur should play an avowed part in the treatment of rheumatism and allied disorders, whether it be by Harrogate water, colloid, ichthyol, or the time-honoured mustard. These remarks are prompted by the special medical mustard bran prepared by Messrs. J. and J. Colman, of Norwich and Denmark-street, St. George's-street, London, E. This preparation is claimed to retain heat and moisture longer than other forms of poultice. Samples of mustard prepared particularly for use in the bath were also exhibited.

III. *Special Foods.*

Foods of particular interest in medical practice were not much in evidence, and, generally speaking, this division of the exhibition showed a small following compared with previous occasions. Experts in the preparation of special foods must have found considerable inconvenience by the restricted supply of raw materials through the war, and this fact may account for the small presentation. The chief interest lay in those foods which are claimed to contain the accessory food factors. The composition of some well-known foods

peculiarly useful as accessories in infant feeding proves to have been based unwittingly on the inclusion of these factors.

Virol, for example, of Virol, Ltd., 152, Old-street, London, E.C., is presented in a new dietetic light when we consider that it is made up of marrow and beef fats, malt extract, eggs, lemon syrup, all including, with care in manufacture, the three vitamins unimpaired. Similarly, Messrs. Oppenheimer, Son, and Co., Ltd., of 179, Queen Victoria-street, London, E.C., exhibited samples of "roboleine" based on a collection of well-known materials bearing food accessory factors contained in malted barley, red bone marrow, and neutralised lemon-juice. The preparation is marked by an attractive palatability welcome to the growing child. Full-cream dry milk products were well exemplified in the exhibit of Glaxo by the Glaxo Company of 155-157, Great Portland-street, London, W. This product shows the complete composition of cow's milk minus, of course, the 88 per cent. of water. A claim is made for its vitamin content. In addition to their well-known palatable starchless and sugarless foods for diabetic patients—bread, biscuits, cakes, preserves, and beverages—Messrs. Callard and Co., of 74, Regent-street, London, W., exhibited a new food preparation, vitmar, which we have already noticed in our analytical columns. While showing a high calorific value care has been taken to vitalise the preparation with all three accessory food factors founded on the use of ingredients containing them.

IV. *British Spas.*

The formation of a British Spa Federation will be welcomed as indicating the waking up of the authorities of our home watering-places to the health assets they possess. There was ample illustration of this in the exhibits of these resorts. Considering the limited area of our islands, the natural balneological resources are remarkable. There is Bath, with its impressive supply of hot water (120° F.) amounting to half a million gallons daily, and reeking with radium emanation. There is Harrogate, with its famous sulphur waters and its magnesia and chalybeate wells amidst a most attractive and health giving environment. There is Buxton, also situated amongst charming surroundings, with its thermal and radio-active springs. There is peaceful Cheltenham, with its natural aperient waters; Droitwich, with its brine wells; Woodhall Spa, with its saline water in which iodides count as important therapeutic constituents. Sulphur, again, is presented in the waters of Llandrindod Wells. All these establishments possess accessories in the shape of electrical apparatus, light and heat treatment, and mechanical balneological appliances, now recognised as giving relief in many cases. The authorities are realising also that régime is an important insistent in treatment, and that patients rightly expect healthy amusement and occupation to make their visit enjoyable as well as medicinal.

V. *Literary Exhibits.*

A much appreciated section of the exhibition was its literary side, comprising a group, so to speak, of small libraries presenting recent medical works, standard text-books, monographs, and so on. Amongst the publishers showing material in this division were: Messrs. H. K. Lewis and Co., Ltd., of 136, Gower-street, London, W.C.; the Cambridge University Press, of Fetter-lane, London, E.C.; Messrs. D. Appleton and Co., of 25, Bedford-street, London, W.C.; Mr. E. A. Brooke-Williams, of 8, Henrietta-street, London, W.C.; Mr. Edward Arnold, of 41-43, Maddox-street, Bond-street, London, W.; the J. B. Lippincott Co., of 16, John-street, Adelphi, London, W.C.; Mr. William Heinemann, of 20, Bedford-street, London, W.C.; the W. B. Saunders Company, Ltd., of 9, Henrietta-street, Covent-garden, London, W.C.; Messrs. Macmillan and Co., of St. Martin's-street, London, W.C.; Messrs. John Wright and Sons, of Bristol; the Oxford Medical Publications, of Warwick-square, London, E.C.; and Mr. H. R. Ellis, of 9, Lovell's-court, Paternoster-row, London, E.C. The collection was significant of a revival of medical literature since peace was established.

Public Health.

REPORT OF THE LONDON COUNTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER, 1919.

UNDER the above title Dr. W. H. Hamer has presented to the London County Council a combined report which, like its several predecessors, abounds with important considerations for the welfare of the dwellers in the metropolis. We give here a brief survey of its main features, reserving for future comment many important matters of detail.

By including his remarks on elementary education in the same volume with his advice as official guardian of the public health Dr. Hamer indicates his adherence to the conviction that the time-honoured system of separate treatment of these subjects is not only indefensible but actually wasteful. The recent decision of the County Council to amalgamate, under one administration, two previously independent departments has been abundantly justified by subsequent experience.

General Health Lessons.

In a prefatory note Dr. Hamer reviews the more important lessons inculcated during 1919 after five years of war and under the exceptional strain and stress then endured. In certain respects he regards 1919 as a record year. "The hand of war, famine and epidemic disease (he writes) was still outstretched over Central and Eastern Europe, though it is difficult to assess with any degree of accuracy the amount of misery and privation prevailing there. On the other hand, in the two largest aggregates of population—New York and London—the year was one of phenomenally low mortality. Conditions arising out of the war continued, in large measure, to dominate the situation throughout the world, though their effect upon the death-rates in 1919 was so dissimilar in the places above referred to." The experience of the last 70 years, in which hygiene and preventive medicine have made so much progress, shows that following upon a time of conflict and strife there almost inevitably succeeds an era not so much pacific as hypercritical, and Dr. Hamer is unwilling to follow the parrot cry of "physical deterioration" among the people. So far as infectious disease is concerned, he admits that it is the post-war period rather than the war period itself that threatens the safety of civilians dwelling outside the area of hostilities.

For nearly six years civilian migration into and out of this country has practically ceased. It is only now, nearly 18 months after the armistice, that there is any prospect of resumption of the pre-war movements of emigrants passing through London on their westward way. The year was essentially a period of transition from the war conditions of 1918 to so-called normal conditions towards the close of 1919. The majority of the war refugees were repatriated early in the year, and with the return of American and Colonial troops and the demobilisation of British forces there resulted, by the middle of the year, an addition of about 400,000 to the London population. It is therefore specially gratifying to learn that the mortality in the latter half of 1919 was lower than in any corresponding period for many years.

Infectious Diseases.

Taken as a whole, the year under notice was one of exceptionally favourable mortality, although there was considerable increase in the loss of life from influenza and allied causes in its first quarter. Except for a fortnight of cold and inclement weather in February the meteorological conditions were favourable to health. The exceptional immunity from infectious maladies experienced in the few years immediately preceding was not maintained in 1919; the number of notifications was, however, still below the average. *Diphtheria* showed increased prevalence, the attacks being in excess of those of any year since 1902. *Scarlet fever*, which had fallen to a minimum incidence in 1917, has

since steadily increased, both in London and in the provinces, and there is now every prospect of another period of greater prevalence. *Typhus* was epidemic in many parts of Europe during 1919, but only two cases were notified in London. *Dysentery* caused 86 deaths, as against 313 in the previous year. *Enteric fevers* showed still further decline on the remarkably low rate of recent years. The low incidence of these diseases is the more remarkable because the population of London was, owing to demobilisation, temporarily increasing by immigration from all parts of Europe. But while the civilian community has escaped thus lightly, there was still unusual prevalence of typhoid in certain of the London mental hospitals, though the attacks there were less than half as many as those registered in 1918. The remarkable freedom of the army from this disease, as compared with earlier military experiences, has been widely ascribed to preventive inoculation. But on this point Dr. Hamer remarks that whatever the conclusion may be with regard to the soldiers, it is clear that this explanation cannot hold with regard to the civilian population, for only a small percentage of these were inoculated, and yet the number of attacks amongst them since 1914 has distinctly fallen.

Tuberculosis.—Among the civilian population the deaths referred to pulmonary tuberculosis numbered 5332, and to other forms of that infection 992, both these numbers being far below those of the previous year. The notified cases of "primary tuberculosis" totalled 15,587, a number below the average in the previous five years.

Influenza, cerebro-spinal fever, poliomyelitis.—In the last report Dr. Hamer suggested that "all the above-named forms of epidemic disease were manifestations of one and the same influence." This year he returns to his argument in favour of a common infecting agency in regard to the associated prevalence of disease, encountered coincidentally with influenza in its pandemic phase. Recent bacteriological literature encourages him to regard bacterial mutation as a phenomenon demanding careful investigation.

Birth-rate and Infantile Death-rate.

Estimates of the civil population have been based, since 1914, on the National Register of 1915, supplemented by information connected with the rationing of food. The civil population of London County thus estimated was 4,358,309 in the year under notice, an increase of 403,755 on the estimate of the previous year. The Registrar-General estimates the County birth-rate at 18.2 per 1000 living, as compared with 16.0 in 1918. A rapid increase in the registered births was noted in the latter half of the year, and in the closing weeks of that period the numbers far exceeded even pre-war figures. The civilian death-rate in 1919 is estimated at 13.6 per 1000, as compared with 19.2 in the preceding year. Among infants under 1 year the mortality was only 85 per 1000 births—the lowest rate on record. The notably light mortality from measles and whooping-cough largely accounts for this saving of infant life; but in addition to this the deaths from tuberculous and other respiratory affections were below the average, notwithstanding the influenza epidemic.

Medical Inspection and Treatment of School Children.

In this section Dr. Hamer gives an interesting account of the efforts of his department for the improvement of the health and physical condition of school children. The total number of children medically inspected during 1919, exclusive of scholarship children, was 265,230, compared with 255,631 in the preceding year. It is gratifying to note that with regard to more than three-quarters of the children entering school a parent interviews the doctor and obtains his advice concerning the precautions necessary in the interest of the child's health. The proportion of children found in need of treatment for physical defect was slightly lower than in the previous year. At routine inspections 83,007, or 42.6 per cent. of the children examined, were referred for treatment, as against 44 per cent. in the previous year.

From an instructive table the variations are shown in the condition of the children under the headings

of clothing, nutrition, and cleanliness. Based on the huge number of 200,000 examinations yearly these figures give valuable indications of the changes brought about in the condition of the people by varying economic and social influences. During the years of war this information became an encouraging feature, "demonstrating as it did that the children were not only shielded from the stress of war conditions, but that they were more tenderly looked after during those gloomy years than they had been in the previous piping times of peace." It is legitimate to dwell upon all improvements in the condition of children, but such improvement must not blind us to the ever present truth that there still are with us many children suffering from malnutrition, parasitic contagion, and ill-health. It is more than ever necessary to scrutinise these conditions during the difficult times through which we are passing or may be about to pass. In regard to *sufficiency of clothing* we learn that the percentage of children insufficiently clad was 2.5 in the year under notice, against 2.2 in 1918. Infants continue to be better cared for in this respect than older children, and girls are always better clad than boys. As to *nutrition* the condition of children progressively improved, until in 1918, as compared with the pre-war years, there were less than half the number of ill-nourished children in the schools. In 1919, however, there was perceptible deterioration of nutrition. It is to be feared that this must be attributed to the rise in price of the foods most needed by children, and notably in the cost of milk. In the year under notice 6.1 per cent. of the children were under-nourished, against 5.5 per cent. in 1918. As regards *personal cleanliness* and measures for securing freedom from verminous infestation the report is very instructive. In 1916 and 1917, for example, the percentage of 8 year old girls with heads free from parasitic infection was 68.8, whilst in 1919 it was 74.2. Striking improvement at other ages is also recorded during the last two years. It is clear, however, that the time has not yet arrived when the campaign against these dirt conditions can with safety be relaxed.

Institutions for medical treatment.—At the close of the year under review there were 57 centres actually at work for the treatment of school children. The total number of cases for which facilities are thus provided was 174,878. These figures may be compared with the 42 centres providing for 99,000 cases in 1914 or with the 17 centres providing for 26,000 cases in 1910, the year in which the medical treatment scheme was inaugurated.

URBAN VITAL STATISTICS.

(Week ended July 17th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 10.1, 9.9, and 9.9 in the three preceding weeks, was again 9.9 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 10.1, or 0.5 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 2.8 in York, 3.4 in Lincoln, and 3.9 in Ilford, to 15.3 in Merthyr Tydfil, 15.7 in Sunderland, and 17.5 in Wolverhampton. The principal epidemic diseases caused 180 deaths, which corresponded to an annual rate of 0.5 per 1000, and comprised 68 from infantile diarrhoea, 34 from diphtheria, 33 from measles, 30 from whooping-cough, 12 from scarlet fever, and 3 from enteric fever. Measles caused a death-rate of 1.6 in Wolverhampton, 1.7 in Stockton-on-Tees, and 1.8 in Northampton; and whooping-cough of 1.3 in Gateshead and 1.5 in Merthyr Tydfil. There were 1855 cases of scarlet fever and 1582 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1755 and 1599 respectively at the end of the previous week. The causes of 22 of the 3381 deaths in the 96 towns were uncertified, of which 4 were registered in Birmingham and 4 in Gateshead.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 11.5, 11.1, and 12.1 in the three preceding weeks, fell to 11.1 per 1000. The 268 deaths in Glasgow corresponded to an annual rate of 12.6 per 1000, and included 4 each from small-pox and infantile diarrhoea, 3 from whooping-cough, and 1 each from

measles and scarlet fever. The 66 deaths in Edinburgh were equal to a rate of 10.1 per 1000, and included a fatal case each of measles and diphtheria.

Irish Towns.—The 125 deaths in Dublin corresponded to an annual rate of 15.7, or 1.5 per 1000 above that recorded in the previous week, and included 4 each from whooping-cough and infantile diarrhoea and 2 each from measles and diphtheria. The 94 deaths in Belfast were equal to a rate of 11.9 per 1000, and included 2 each from enteric fever and infantile diarrhoea and 1 from scarlet fever.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Cmdr. J. St. J. Murphy placed on retired list medically unfit.

ARMY MEDICAL SERVICE.

Major-Gen. S. Macdonald retires on retired pay.

ROYAL ARMY MEDICAL CORPS.

Capt. F. C. Davidson retires, receiving a gratuity, and is granted the rank of Lieutenant-Colonel.

Lieut. W. H. Palmer to be Captain.

Officers relinquishing their commissions:—Temp. Capt. A. Brown (granted the rank of Lieutenant-Colonel). Temporary Captains granted the rank of Major: A. C. Norman, W. Dunlop, G. Young. Capt. W. H. Palmer (retains the rank of Captain). Temporary Captains retaining the rank of Captain: S. P. Hyam, J. E. Kesson, J. P. Howe, R. T. G. Aickin, W. Leslie, A. Morrison, M. A. MacDonald, W. W. Morrison, J. W. Robertson, G. B. Egerton, L. J. F. Bull, M. McGillivray, H. Morley, E. ff. Creed, I. M. Robertson, T. H. J. Douglas, B. Sergeant, J. M. H. Campbell, J. B. Kirk, D. C. Buchanan, J. Irving, E. J. Coombe, R. Hilliard, G. P. W. Staunton, J. K. T. Mills, G. P. N. Richardson, C. G. Coombes, J. H. Thomas, R. T. Lewis, C. C. Harrison, W. D. Miller, J. R. Harris, W. Dempster, W. M. Jones, R. W. H. Miller, H. W. Lewis, G. M. Herriott, R. Thom, C. V. Pink, L. P. Johns, P. D. McLaren, O. St. L. Campion, C. V. Pearson, W. R. McLinden, H. St. H. Vertue, W. Oats, F. B. Jago, R. H. Chadwick, W. F. Kivlichan, T. R. Wilson, H. N. Pritchett, C. E. H. Paley, M. M. Frew, W. B. Bannerman, G. de H. Dawson, A. Coupe (on ceasing to be employed as a Dental Surgeon). Temp. Lieut. J. C. J. Callanan (retains the rank of Lieutenant).

Oversea Forces: South African Medical Corps.—The undermentioned relinquish their temporary commissions on ceasing to be employed: Lieut.-Col. Sir E. N. Thornton (retains the rank of Lieutenant-Colonel); Capt. H. R. J. Sutton (granted the rank of Major) and R. P. Mitchell (retains the rank of Captain).

The undermentioned relinquish their commissions on account of ill-health: Major M. R. C. Hoare (retains the rank of Major); Capt. P. D. Hamilton and H. J. Orford (granted the rank of Major) and Capt. R. I. Wolfe (retains the rank of Captain).

Temp. Capt. J. M. Mitchell, R.A.M.C., has been appointed an Officer of the Military Division of the Most Excellent Order of the British Empire for valuable services rendered in connexion with military operations in South Russia.

SPECIAL RESERVE OF OFFICERS.

Capt. B. W. Brown relinquishes his commission and retains the rank of Captain.

TERRITORIAL FORCE.

Capt. F. E. Stokes to be Major.

Capt. S. S. Greaves to be Deputy Assistant Director of Medical Services, West Riding Division.

Major H. Fulton resigns his commission and is granted the rank of Lieutenant-Colonel.

Capt. (acting Major) E. G. T. Poynder relinquishes the acting rank of Major.

Majors resigning their commissions and retaining the rank of Major: G. W. Fitzgerald and H. A. T. Fairbank.

Capt. O. L. Rhys and A. C. F. Turner resign their commissions and are granted the rank of Lieutenant-Colonel.

Captains resigning their commissions and granted the rank of Major: W. V. Wood, J. H. Lloyd, S. H. Rentzsch, W. B. Hill, S. R. R. Matthews, C. E. W. MacDonald, and R. G. Dixon.

Captains resigning their commissions and retaining the rank of Captain: T. I. Mills, H. W. Bayly, E. H. Coyne, D. Davidson, C. W. Fort, P. McRitchie, C. P. Sargent, and A. C. Wilson.

2nd Western General Hospital: Capt. G. E. Loveday resigns his commission and retains the rank of Captain.

1st Eastern General Hospital: Capt. W. L. Murphy resigns his commission and retains the rank of Captain.

1st Scottish General Hospital: Major Sir H. McI. W. Gray resigns his commission and is granted the rank of Colonel.

Lowland Divisional Sanitary Section: Capt. T. J. Mackie resigns his commission and retains the rank of Captain.

TERRITORIAL FORCE RESERVE.

Col. D. W. C. Jones resigns his commission and retains the rank of Colonel.

Capt. E. G. Gauntlett resigns his commission and is granted the rank of Major.

Capt. B. K. T. Collins and C. C. Ling resign their commissions and retain the rank of Captain.

ROYAL AIR FORCE.

Capt. J. P. Hennessy and J. Chambre are transferred to the unemployed list.

Correspondence.

"Audi alteram partem."

THE MYOCLONIC FORM OF ACUTE EPIDEMIC ENCEPHALITIS.

To the Editor of THE LANCET.

SIR,—Probably one of the earliest recorded cases of the condition in this country was the one shown at the meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on Jan. 24th, 1919. The child, a little girl of 2 years 11 months—curiously enough, an Italian—was under my care at the Hospital for Sick Children, Great Ormond-street, in 1918. Some Fellows of the society held the case was an encephalitis. I maintained it was a myoclonus multiplex, knowing that this was a safe position, since neither the cause of encephalitis nor myoclonus was absolutely clear. The onset was abrupt and the case described in fair detail in the *British Journal of Children's Diseases*, Vol. XVI., No. 187-189, pp. 156-157. It would appear both views were correct—an amiable solution. I followed the case to a fair recovery 18 months later.—I am, Sir, yours faithfully,

F. JOHN POYNTON, M.D.

Devonshire-place, W., July 21st, 1920.

To the Editor of THE LANCET.

SIR,—The cases described by Dr. A. W. M. Ellis in THE LANCET of July 17th are less novel in England than may be thought. Dr. W. B. Russell, for example, described one in your columns in 1918 (July 27th). But, as a matter of fact, when acting as medical registrar at the London Hospital in 1918 I saw many such. Unfortunately, owing to the precipitancy with which the name "encephalitis lethargica" had been adopted by the Local Government Board, and the early and resolute conviction of so many that we had to deal with an affection of which lethargy was the specific index, it became extremely difficult to excite interest in the myoclonic phenomena of lethargic cases, or in those cases with no lethargy but much myoclonus. It was, indeed, not realised that we had to do with a perfect shower of cases exhibiting, severally and collectively, almost every conceivable manifestation of acute encephalo-myelitis and meningitis. However, at the discussion on Epidemic Encephalitis at the Royal Society of Medicine (Oct. 15th, 1918) I stated that, of 127 cases seen in the first half of the year (of which 120 were at the London Hospital), 15 manifested epileptiform "fits," 2 showed marked trismus, and 22 tremors, twitchings, or chorea in a marked degree. These statements excited obvious risibility, but I have the full notes still in my possession. Moreover, I pointed out that of 51 cases submitted to lumbar puncture 4 showed cerebro-spinal leucocytosis in excess, and 2 others in marked excess, whilst some lymphocytosis was present in 31.

In an earlier communication¹ it had been already suggested that, as now generally recognised, cell excess in the cerebro-spinal fluid from cases of encephalo-myelitis is related to the extent and degree of meningeal implication present. But, in a personal letter to me, dated June 19th, 1918, the late Sir William Osler, after writing what I cannot forbear to repeat—that the paper just referred to was "the most sensible thing written on the subject"—went on to say that "encephalitic features of this outbreak are most interesting, particularly the choreiform movements and incoördination."

Sir William Osler, who lectured at Oxford on this myoclonic form in June, 1918, brought all these cases, whether lethargic or convulsive, together with acute anterior poliomyelitis, under the same heading—acute epidemic encephalo-myo-meningitis. And it is this view which is destined to prevail. The epidemiological phenomenon remarked by Dr. Ellis (the "tendency of the virus to new localisation") is, of course, quite familiar in

respect of many epidemics. In some epidemics of diphtheria, for example, many cases are nasal; in others there is a high percentage of laryngeal cases; in others, again, there is much paralysis of this, that, or the other type. And the historical records of epidemic encephalo-myelitis and meningitis show clearly what Wickman proved for the limited Heine-Medin conception; that, though in each epidemic all types are recognisable, nevertheless in different epidemics different types preponderate. The old Kriebel-krankheit and Willis's convulsive fever of 1661 were of the myoclonic type, but Saillant, in 1776, hit the nail on the head when, in describing the "*maladie convulsive épidémique attribuée par quelques observateurs à Vergot*," he pointed out that, in successive epidemics, the clinical phenomena tend to assume different forms.

All the forms noticed and described by me at the London Hospital in 1918 have since been described by different authors as "new affections" or "new types," and it was a case of the myoclonic type which, becoming certified as "acute delirious mania," convinced me of what I had long suspected—that Luther Bell's disease—"acute delirious mania"—is but an encephalitis occurring during influenza periods, with psychical symptoms paramount.

I am, Sir, yours faithfully,

Wimpole-street, W., July 19th, 1920. F. G. CROOKSHANK.

To the Editor of THE LANCET.

SIR,—I am grateful for the excellent account by Dr. A. W. N. Ellis of three fatal cases of acute epidemic myoclonic encephalitis in your last issue. After reading most of the available literature on the subject of acute encephalitis lethargica (in the English language), and observation of some cases in my practice during the first three months of the year, and a few cases of the myoclonic variety in consultation with some of my colleagues during the last three months, I am still far from being convinced that the disease is a distinct entity of its own.

From purely clinical observations of the cases seen by me, with no available opportunities for the more thorough study of them, such as blood examinations, chemical and pathological examinations of the urine and cerebro-spinal fluid, &c., I have yet to be convinced that these conditions are not really influenzal or post-influenzal manifestations. The cases observed by me in the early months of this year were to me obviously influenzal. In one of the cases a condition of marked myoclonus of one upper limb was a distinct sequela a week or so after the patient recovered from his lethargy. In another persistent vomiting was present, which soon only manifested itself when the patient moved her head to one or other side. This then improved, and for a further 10 to 14 days she only vomited if she sat up in bed. I saw a very similar case to the latter with a colleague only last week.

In 1903, whilst engaged as assistant in a large industrial area during an influenza epidemic not of a virulent type, I had one instance of the same myoclonic condition in the left arm as a sequela, which ultimately disappeared with no special treatment.

I have just received the current number of the "Medical Clinics of North America." The first article is devoted to "Encephalitis Lethargica," written by no less an authority on nervous diseases than Dr. Charles Louis Mix, of the Mercy Hospital, Chicago, and in discussing the ætiology he states as follows: "Personally, I am of the opinion that although the germ of encephalitis lethargica has not been discovered, it is nevertheless a post-influenzal affair." The publication of further cases of encephalitis lethargica, whether "myoclonic" or "amyoclonic," with the available minute examinations and equipment necessary for their detailed study, will undoubtedly pave the way for a thorough and complete knowledge of the ætiology and pathology of these most interesting conditions.

I am, Sir, yours faithfully,

July 19th, 1920.

GENERAL PRACTITIONER.

SETTLEMENTS FOR CONSUMPTIVE EX-SERVICE MEN.

To the Editor of THE LANCET.

SIR,—In the *Ex-Serviceman* a discussion has been going on for some time as to the inadequacy of the after-care provision for tuberculous ex-Service men after they have left the sanatorium. A suggestion has been made by a gentleman writing from the Royal Colonial Institute that a colony should be founded in some of our overseas possessions to which suitable men with arrested or quiescent lesions might be sent. Jamaica is said to be an ideal place for the consumptive settler; not in the plains but high up in the Santa Cruz mountains, near Malvern. If the scheme matures the question of funds may bar it. Would Dr. Batty Shaw consider this a suitable opportunity to test the value of a tuberculosis settlement in a dry warm climate, where the chance of mixed infections and catarrhs of the lung would be minimal? I refer to his instructive lecture reported in THE LANCET of Jan. 24th last.

I am, Sir, yours faithfully,

J. PIRIE, M.D.

Moorlands, Canford Cliffs, Bournemouth, July 18th, 1920.

HIBERNATING MOSQUITOES AS CARRIERS OF MALARIA.

To the Editor of THE LANCET.

SIR,—Will you kindly permit me to endorse Colonel S. P. James's remarks contained in your issue of July 10th (p. 99) regarding the importance of Dr. C. M. Wenyon's observation that in the Balkans anophelines with partially developed malaria zygotes hibernate there in the winter. So far as the epidemiology and preventive measures of malaria in India are concerned, this observation may be one of primary importance.

I have elsewhere expressed the opinion that in many stations of the United Provinces and Punjab in India infection through anophelines occurs for one or two months during the late spring and early summer if in March or April there happen to be some heavy falls of rain. This means that under these circumstances there may be two malarial seasons in such places—one, which is short, in the late spring and early summer, and the usual one during and after the monsoons have begun. When this observation was originally made I could give no evidence in support of it except that of the malaria statistics of certain districts and the existence of breeding-grounds of anophelines, in which their larvæ were found during the period specified at several stations; it should not be difficult to prove or disprove in such places, as there are always in existence breeding grounds for anophelines and cases of residual malarial infection. Further work from, say, the middle of March to the middle of May should elicit whether this is actually the case or not, and whether malaria-carrying species of anophelines disseminate malaria at that particular time of the year. This could be ascertained by taking a sufficient number of anophelines in native huts at that time and determining the sporozoite-rate.

I have also noted that there are some stations in which the winged malaria-carrier cannot be found after Oct. 15th, others in which it may be found at the end of October and well into November. In all stations in Northern India a certain number of anophelines continue on the wing and carry malaria for weeks or even months after the breeding season is over. For the observations that led to my originally expressing this latter opinion I was indebted to a suggestion contained in that excellent book, "The Practical Study of Malaria," by J. W. W. Stephens and S. R. Christophers. When these statements were made it never struck me that anophelines could hibernate in the infected state throughout the winter, and I believe that as regards India this has not hitherto been suggested, or I have not come across it if it has. Several malariologists in India have advocated the destruction of hibernating mosquitoes with the view to reducing the numbers that would come into operation when the breeding season began again, but not

with the idea that some of these hibernating insects were already infected. The hibernation of adult anophelines on the plains in India is carried out mainly in secluded sheltered corners of houses, under surface of shelves, unused almirahs, up chimneys, in store-rooms, stables, servants' out-houses, in huts of bazaars, in cow-byres, and old ruins, in which these mosquitoes creep into cracks that often appear too small to give them admission. There would be no difficulty in collecting these, and if they are malaria-infected estimating the zygote-rate for each month during the hibernating period.

In India we have been in the habit of considering that the cases of spring malaria occur as relapses of old infections brought on by the chills due to lowered atmospheric temperature and winds associated with the "spring-crops showers" of March and April, and that these residual malaria cases then form the reservoirs from which the new broods of anophelines disseminate infection. Colonel James, in his recently published book, "Malaria at Home and Abroad" (which should be considered a *vade mecum* by all practical investigators of malaria), states at p. 94 "..... as regards initial malaria in England in 1918 there are records of a few new infections as early as May. An infection in May or earlier must have been due to an anopheline which has lived through the winter, for in that year the first brood of new adult anophelines did not appear until quite the end of the month. The particular anopheline concerned might have become infected in the previous autumn and lived through the winter with sporozoites in its salivary glands, or, as was suggested by Captain Macdonald, R.A.M.C., it might have been wintering in an artificially heated room occupied by a malaria carrier." Several important suggestions are embraced in these remarks. It is too late to start observations in India regarding anophelines that possibly hibernated in the infected state last winter, but it is not too early to commence organising a series of investigations for the ensuing cold weather that would settle this highly important question once for all as regards that country.

In general terms it may be stated that up to date in India antimosquito measures are closed down when the breeding season of mosquitoes terminates, and, as a rule, not recommenced until the ensuing rainy season. If it is found that some of the malaria-carrying species of anophelines do hibernate in the infected state our position in connexion with antimalarial measures is greatly strengthened and a new line of defence is opened out—that of devising measures of destroying them in their winter quarters. Special interest will be felt in Dr. Wenyon's promised paper on his experiments in connexion with hibernating infected anophelines in the Balkans.

I am, Sir, yours faithfully,

P. HEHIR,

London, July 12th, 1920.

Major-General, I.M.S. (ret.)

FUNCTIONAL NERVOUS DISORDERS.

THE CAUSAL FACTORS.

To the Editor of THE LANCET.

SIR.—It is unfortunate that Dr. Judson Bury in your issue of July 10th did not define the neuroses that he dealt with in his paper on the Physical Element in the Psycho-neuroses. He described hysteria and neurasthenia, but ignored psychasthenia. Let us, therefore, turn to the simplest definition and classification, that of Purves Stewart:—

(a) *Neurasthenia*.—A disease resulting from the hypersecretion of the endocrine glands, the stimulation of which may be physical (toxæmia, trauma, &c.) or psychical (worry, fright, &c.). If we accept this definition, and I cannot see how we can do otherwise, we can at once see how a long past stimulus is capable of being a causative agent in a present neurosis; thus: stimulus → hypersecretion of adrenals → "quicker living" → exhaustion and consequent demand for more secretion → hypersecretion, and so on.

(b) *Hysteria*.—Purves Stewart accepts Hurst's definition:—"That hysteria is a condition manifesting itself by symptoms which can be reproduced by suggestion, and which can be made to disappear again by persuasion and suggestion."

Dr. Bury does not; but as he fails to give us anything in its place, we may for the purpose of this argument adhere to Hurst's ideas.

(c) *Psychasthenia*.—As Dr. Bury does not mention this neurosis we need not deal with it here.

It will be noted that the conditions known as "anxiety-neurosis," "conversion hysteria," &c., are included in the above; and, surely, rightly so. For instance, anxiety is a symptom present in all the psychoneuroses; if it predominate in any one case, why label the ailment "anxiety-neurosis" and push it into a class by itself?

Let us now see wherein those who claim "mental factors as much more important than bodily" differ from Dr. Bury.

Neurasthenia.—So far as I am aware psychotherapy does not claim to be able to cure this disease; moreover, the vast majority of psychotherapists are in practical, if not entire, agreement with the paragraph on the biochemic aspect. In fact, we can say that neurasthenia is not a true psychoneurosis; it is an organic disease which will yield, not to psychotherapy, but to "fresh air, sunlight, cheerful surroundings, and light work"; in two words, physiological rest. However, "anxiety states" so often occur in true neurasthenia that psychotherapy is a useful adjunct in treatment.

Hysteria.—Dr. Bury describes an illustrative case and then develops his argument that the causative factor is physical and in the nature of a "synaptic breakdown." Possibly; but may I suggest that he observe his patient when recovering from a general anæsthetic, or better still, under hypnosis? In similar cases, when there has been any reason to anæsthetise them, I have always found that the nervous elements involved were intact. For example, I have in my care at present a patient who is stone deaf, and also afflicted with such a spasmodic stammer that he is practically dumb. Note that here we have not only muscles involved, but also a special sense.

A few days ago I anæsthetised my patient deeply, and then, as he was coming round, I began talking to him in an ordinary conversational tone. After a little while he replied when called by name, and finally, when I told him to converse with an orderly by the bedside, he did so. At this time his hearing was perfect, and so was his speech. A few minutes later, as he recovered from the anæsthetic, his hearing and speech left him in the middle of a sentence. Now, are we going to say that this man is suffering from a "block in his synaptic connexions"? How can an anæsthetic remove this block? (Note that at the time of the "recovery" the patient was only *partially* and lightly "under.")

How can the "synaptic block" act so that return to consciousness was accompanied by a dramatic relapse? Is it that this man is a malingerer? Well, he has been under close observation for five months, not only by M.O.'s, but also by orderlies, and not a shred of evidence that he is a malingerer has been noted; moreover, from a disciplinary point of view he is an excellent patient. Personally, I fully believe that he has no conscious control over his ailment, and I cannot see how the causal factor can be anything but psychical.

I am, Sir, yours faithfully,

A. G. MIDDLETON,

Medical Superintendent, John Leigh Memorial Hospital (Neurological), Brooklands, Cheshire.
July 15th, 1920.

A PLEA FOR A UNIFORM PSYCHOTHERAPY.

To the Editor of THE LANCET.

SIR,—Of recent years, more especially since the war, the treatment of disorders of functional origin has been occupying an ever-increasing amount of medical and public interest. For the practitioner in general work the nomenclature employed by psychopathologists must be bewildering. Not only does this apply to the terms in use for describing the disorders themselves, but to the mechanisms producing these disorders, and even the methods of treatment are described by authors belonging to different schools of thought in language the meaning of which varies with the individual writer.

One reason for this, although perhaps not the only one, is that the work of Freud, Jung, Adler, and others has laid stress upon an entirely new conception of the mind—namely, the "unconscious." As Mr. Tansley points out

in his recent book, psychology, prior to the work of the psycho-analytic school, concerned itself mainly with the study of the mind by introspection, and therefore dealt only with facts of phenomenal consciousness. Of recent years, however, the results of this form of investigation have failed to satisfy even the academic psychologist, so that he, in common with others, has sought for psychological conceptions yielding results of a more practical nature. The widespread interest aroused by the conception of an area of the mind outside consciousness, which directs and governs consciousness, seems to be the result of this discontent. In this country, as well as on the continent, numbers of books have been written dealing with the mental mechanisms first outlined by Professor Freud, and with the views of his adherents and opponents. Such books are either purely psychological or designed for the better understanding of nervous disorders, in which case they are of direct interest to every medical man called upon to treat patients so suffering.

Prior to 1914 psychopathology and psychotherapy were studied by few medical men, and treatment of functional disorders by mental medicine was carried out by a relatively few physicians. At the present time, however, there are a large number of individuals, both within and without the profession of medicine, who essay to treat derangements of nervous origin by means of psychotherapy. It is obvious that treatment should be carried out by those trained in the practice of medicine rather than by members of the laity, whose experience is often confined to the perusal of psychological treatises, and this if only for diagnostic reasons. The importance of this will probably be sufficiently emphasised by referring to an article by Dr. Judson Bury in the issue of THE LANCET of July 10th. This author lays stress upon the physical element in the causation of the psycho-neuroses; and I venture to think that this aspect of the subject must perforce be overlooked by the layman who treats patients by psychological means. But the majority of medical men, whose experience of the treatment of these disorders makes their opinion of value, are agreed, I believe, that in psycho-neuroses, certainly of any long standing, both physical and psychical changes are generally obvious, and that treatment, therefore, need not be confined to one method.

If, therefore, it is agreed that treatment by psychotherapy is better carried out by qualified practitioners, it is necessary that medical men should be conversant with a nomenclature in general use and should be able to form some judgment as to which patients are suitable for psychotherapeutic treatment, either by the doctor himself or by a specialist. At the present time, however, conflicting statements on this subject appear almost every week in the medical journals; and it is no uncommon occurrence for the same number of a journal to contain two articles on some aspect of this subject, which are not only written by authors whose views are diametrically opposed, but which are even in violent opposition. The strides which psychological treatment has made of recent years are, of course, so rapid, that difference of opinion must of necessity exist about much technique which is still *sub judice*. But even with this allowance, the marked difference of opinion which is expressed makes it difficult for practitioners to decide first, whether any psychotherapy is useful, and, secondly, whether the suggestionist, persuasionist, or psycho-analytic school is justified in the claims each makes for its own vaunted method.

Difference of opinion must perforce exist on many subjects connected with a profession such as medicine, which is really in its practice an art more than a science. But such direct contradictions as exist on this subject are surely capable of some adjustment, and the object of this letter is to plead, primarily, for a single nomenclature for functional disorders and their treatment. This would seem to be the starting-point for a scheme more acceptable to the bulk of medical psychologists, and hence a better understanding by the general practitioner of the aims and capabilities of the psychotherapist. It is impossible for the busy doctor to make himself conversant with the claims made by

the Viennese and Zurich schools, or to contrast these with the indictments launched by those who still regard the psychoneuroses as mainly or entirely psychogenic. As a result many patients are recommended for a particular variety of psychotherapy who would never be so advised were the limitations of the treatments included under this term more generally understood.

On the other hand, many functional ailments continue to exist under the inadequate attack of drugs, electricity, and massage which could be conquered with ease by a suitable psychotherapeutic procedure. Of these two classes, I am inclined to think that the latter is the larger and more important.

The physico-genic school, to whom psychotherapy is synonymous (certainly in many instances) with moral encouragement and occupation, is imbued with the idea that every medical man can and does practise psychotherapy when he encourages and exhorts his patient, but that beyond this the specialist can do little. Another belief of many is that only "hysterical" or weak-minded individuals are suitable for this method of treatment. In other words, that every person requiring such help must perforce be what has sometimes been dubbed a "degenerate." Every specialist is assumed to have some special knowledge and skill in the practical side of his craft, if only by the constant practice which brings experience in its wake; and we learn to cure by curing, whether we do so by surgical or mental operations. The sole fallacy of this argument might be found in the belief that no especial technique existed for a mental operation, if this belief could be established as a fact. This is, however, far from the truth, as all who have practised psychotherapy know. It matters not whether he believes in the artificial dissociation provided by hypnosis, or the associationistic delving of analysis, the physician who operates on the mind learns that the technique which suits him is the technique which cures his patients. We may assume, therefore, that the experienced psychotherapist has acquired some skill which makes him especially able to treat his patients.

The services which psychotherapy can perform will never be successfully decried by those who can only think in terms of protoplasm; its development is more likely to be delayed by internecine strife and by the bitterness of opposing schools. This letter is a plea for a more uniform nomenclature, for a better understanding of a rational psychotherapy, and for a wider use of the methods included under this term.

I am, Sir, yours faithfully,

IVO GEIKIE COBB.

Queen Anne-street, W., July 14th, 1920.

THE CLINICAL DIAGNOSIS OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I shall be obliged if you will publish this, my final contribution to the discussion, *re* "The Clinical Diagnosis of Diphtheria." Any further correspondence would, I feel, be a waste of time, energy, and paper; for Dr. A. K. Gordon's views differ so widely from my own. What I have published has been an exact record of my personal experience. Dr. Gordon says his experience has been different, and his statement must be accepted as true, though it follows that the clinical features of faucial infections must be different in Manchester from what we see in North Wales.

I am glad to find Dr. Gordon saying (near the end of his letter) that "he holds clinical and bacteriological diagnosis to be equally essential because one supplies the deficiencies of the other." Now, Sir, that is precisely my own view, and I have distinctly stated that I employ both methods. My point is that diphtheria can be diagnosed without bacteriology. Dr. Gordon, I think, takes the opposite view, in spite of the fact that Pierre Bretonneau diagnosed and described diphtheria in 1826, about 57 years before the causative germ was discovered by Klebs (1883), and many years before "germs" were suspected of causing any zymotic disease.

I am, Sir, yours faithfully,

H. DRINKWATER.

Wrexham, July 16th, 1920.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE Standing Committee of the House of Commons, to which the Dangerous Drugs Bill has been referred, met on Tuesday, July 13th, and Wednesday, July 14th. The object of the Bill is to carry out the Government's obligation under the Treaty of Versailles to bring the International Opium Convention into force. On both occasions the Committee failed to start work owing to the lack of a quorum. After waiting some time in the hope of a quorum being obtained, the Chairman, Colonel W. G. NICHOLSON, said that the Bill would go to the bottom of the list before the Committee.

HOUSE OF LORDS.

THURSDAY, JULY 15TH.

Veterinary Surgeons' Amendment Bill.

The Veterinary Surgeons' Act (1881) Amendment Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, JULY 14TH.

Typhus Cases in the Black Sea.

Lieutenant-Commander KENWORTHY asked the First Lord of the Admiralty whether His Majesty's seaplane-carrier *Ark Royal* had been used for carrying refugees who were typhus cases in the Black Sea; how many times she had been so used; whether she was disinfected immediately after each voyage; how many cases of typhus there had been among the crew of this ship; how many of the crew had died; and why properly fitted hospital ships were not used for this purpose.—Mr. LONG replied: His Majesty's seaplane-carrier *Ark Royal* was used on one occasion for carrying refugees who were typhus cases in the Black Sea. She was disinfected immediately afterwards. There were 16 cases of typhus fever among the crew in the *Ark Royal*, of whom 8 were landed at Batoum on May 14th last; 5 more landed and sent to the 82nd General Hospital, Constantinople, on May 17th; 1 (Mr. Scott, Warrant Engineer) was also sent to this hospital on May 19th; 1 on May 20th; and 1 on May 27th sent to the 20th Stationary Hospital. Two deaths were reported—namely, Mr. Scott, Warrant Engineer, and Chief Shipwright C. Mattinson. The only hospital ship was not at that time available, and the urgency of evacuation necessitated the use of all available craft.

Cost of Poor-law Relief.

Mr. SWAN asked the Minister of Health if he could state the present average cost of paupers under the Poor-law.—Dr. ADDISON replied: Statistics showing the cost at the present time are not yet available, but in the year 1918-19 the average weekly cost per person in receipt of relief in England and Wales was approximately as follows:—Institutional relief: in infirmaries, 34s. 1d.; in separate schools and other institutions for children, 18s. 2d.; in general institutions, 20s.; domiciliary relief, 5s. 1d.

Glasgow Vaccination Statistics.

Mr. ROBERT YOUNG asked the Secretary for Scotland whether he could state what was the total number of small-pox patients admitted to Belvedere Hospital, Glasgow, since the recent outbreak, and of that number how many had been vaccinated in infancy and since, and how many had never been vaccinated; and whether the number of deaths which had taken place were entirely those of vaccinated persons.—Mr. MUNRO replied in a written answer:—

Small-pox in Glasgow to July 12th, 1920.

Age period.	Unvaccinated.		Vaccinated.	
	Cases.	Deaths.	Cases.	Deaths.
Under 10 years	71	16	1	Nil.
Over 10, under 20	12	4	74	2
Over 20	5	1	182	29
Totals	88	21	264	31
Total cases admitted to Belvedere Hospital				352
Total deaths				52

Of the vaccinated cases 15 have been revaccinated since infancy. Two of these are said to have been revaccinated in 1916, but there is no visible evidence of this.

Third London General Hospital and Tuberculosis.

Mr. GODFREY LOCKER-LAMPSON asked the Minister of Health whether, in view of the treatment urgently required for ex-military and other local tuberculous patients, the

London County Council were desirous of taking over the completely equipped wards in the ground at the back of the 3rd London General Hospital on their vacation by the military authorities at the end of July; whether the London County Council were prevented from doing so by provisions of the Defence of the Realm Act, under which it was obligatory that these huts should then be dismantled and broken up; whether the erection of similar wards elsewhere would cost a sum of not less than £150,000; and what action he proposed to take.—Dr. ADDISON replied: I appreciate very fully the importance of preserving these buildings for the treatment of the civilian population, and I am in communication with the London County Council on the subject.

THURSDAY, JULY 15TH.

Health Services Vote.

THE House went into Committee (Sir F. BANBURY in the chair) on a vote of £17,572,797 for the salaries and expenses of the Ministry of Health, including grants and other expenses in connexion with housing, grants to local authorities, &c., sundry contributions and grants in respect of benefits and expenses of administration under the National Insurance (Health) Acts, 1911 to 1919, certain grants in aid, and certain special services arising out of the war.

Dr. ADDISON, Minister of Health, said that this was the first time that the estimates of the Ministry had been presented to the Committee. He referred to the serious loss which the Ministry had suffered in the first year of its work through the death of Sir Robert Morant, who was at all times a loyal and trusted friend, a great servant of the public, and an example to all of self-denying, far-sighted, resolute patriotism. During the year various services had been amalgamated, including those relating to the Health Insurance Department, the Registrar-General, the work of the Board of Education in regard to school medical services and prospective mothers, the work of the Home Office under the Children Act, and a very important branch of the public service which lately came under its purview, the Board of Control dealing with the whole question of lunacy and other minor services. A number of other services foreign to their interests, particularly railways, roads, bridges, and locomotives, and libraries and museums, had been handed over to other Departments. A great part of the work of the Department had been absorbed during the year in consideration of various aspects of the proposals which would in due time be submitted to Parliament with regard to health services outside the Ministry. It was clear that a sound health policy would require time and patience for its development, and any rash expenditure might be misleading and wasteful. The first essential in any well-defined health policy was the spread of good common information, for the foundation of many of their possibilities was in the home. Any sound system must be based upon the principle of prevention. Hitherto they had not made so much progress in that direction as they might have done. Any proper development of a preventive health service must depend upon an adequate supply of trained persons, and in this respect there was at present in many branches a serious deficiency, which it would take time to remove. Any systematic preventive scheme must offer fairly full facilities for dealing with early disability and have at its service an active prosecution of scientific research. The preventive services developed in this country up to the present, so far as they related to the surroundings of individuals, reached a stage of development beyond that of any other. Our sanitary services were well developed, and it was largely owing to them that the health of the people, many of whom dwelt in most pestilential places, was as good as it was. Speaking of the question of housing, the right honourable gentlemen said that they were now past the final stage in over 200,000 houses, but the tenders had been approved and finally settled in regard to 126,000 houses, the only difficulties being finance and labour. Of the 126,000 houses the contract had been signed and work had been started on the site in respect of 69,887. In addition to this, work had been begun on 70,000 houses, and there were an additional 12,000 where the work had been begun with a subsidy. Over 2000 houses were inhabited and another 5000 or 6000 would be completed in the next month or two. As regards cost, the tender quotation for the same class of house had risen in respect of each house £100 during the last six months. Such a disastrous increase could not go on, and the only way it could be compensated was by a check in the rise in the cost of materials, by getting greater output from labour, and by a national understanding with regard to wages.

Security Against Invasion of Disease.

He was glad to say the sanitary cordon which the Ministry had organised round this country had been remarkably successful in securing it against invasion by disease from other parts of Europe which had threatened at the time of demobilisation. They had arranged with the Treasury, in order to help the Port Sanitary Authorities, to pay 50 per

cent. grants towards their expenses. They had had another danger before them last year—namely, the fear that rested on the minds of people that there would be another influenza epidemic such as had such devastating results the year before. In the first quarter of 1919 37,000 people, mostly adults in the prime of life, died of influenza. They did all they could by arrangements with the Foreign Office to be supplied with information from abroad. They organised a number of experts in other departments, and they prepared documents giving such information as they could to encourage the people to protect themselves against the disease. They also provided a great number of doses of a protective vaccine which was used freely, and though, no doubt, he gave offence to those who were not in sympathy with such methods, he thought they were justified in spending money in that way. Similarly they took steps under Sir David Semple to deal with rabies cases. In no disease was it easier to spend money unwisely than in combating tubercle. They had encouraged the development of accommodation in sanatoriums, and had added more than 2000 beds in the last year. In connexion with the sanatoriums, they had provided 1000 places for training the men and there was a grant for each. Unless the system could be one that began at home and ended in re-creating, as far as possible, a useful unit in the community under healthy conditions, it must in many respects be largely wasteful. They had now a dispensary system developed to a certain extent, but no dispensary system would be successful in preventing tubercle and no sanatoriums would wipe out the disease while people had to live crowded in unhealthy dwellings. Inappropriate or insufficient food and bad conditions of life and work were all a part of the tuberculosis problem. There had grown up in some places the village colony conception of what was necessary, and they had one or two standing illustrations, notably in Cambridgeshire, of the very successful application of that principle. Research combined with supervision by one directing authority were needed if they were to have a properly co-ordinated preventive system. Speaking of venereal disease, Dr. Addison said there was no branch of service in which it was more necessary to have a trained personnel. There had been a substantial increase in the number of persons attending the centres. The total had gone up from 460,000 to 843,000, and the scheme was, so far, only in the beginning. There was a tendency amongst certain protagonists to fall upon one another in regard to the method of dealing with the disease. He exhorted them to fall upon the disease. The war had shown that properly directed efforts could cut short a great number of cases that otherwise would develop into mental deficiency of a permanent kind, and it was necessary clearly to provide that in any future arrangements the authorities should be able to deal with mental cases while they were at an early stage to avoid their being labelled lunatics.

Early Treatment of Mental Disorders.

If a system could be developed for the early treatment of mental disorders many asylums would be unnecessary. To develop the work towards this end post-graduate courses for medical men had been arranged under various authorities, and courses of training for nurses and others for this class of disease were being pushed forward. In no matter was it more important to have trained personnel than in questions affecting the charge of mothers. Hence the importance of maternity and infant welfare homes. It had become clear to him that the thing necessary for success was to have trained personnel at their command in the way of nurses and midwives, &c. Therefore it was arranged last year with the Board of Education to have additional grants for training for health visitors, midwives, &c. That had been taken up very extensively. At present there were 700 midwives under training, and the number of centres where this supervisory work was carried on had increased from 1400 to 1600. The proportion of the population in the country which was now reached by these services increased during the past year from 55 to 61 per cent., a substantial increase on the rural population. Towards the end of the last century and the beginning of this the infant death-rate remained stationary at about 150. It was 154 in 1900 and 154 in 1901. It did not begin to fall until 1906, when it was 132. In 1918 it dropped to 97, and last year it dropped to 89, in spite of the fact that in the last quarter of last year there was the influenza epidemic. The figure for the last three quarters of last year and the first quarter of this year was only 78, or about half what it was 20 years ago. Those children who survived nowadays were better nourished and more likely to be useful members of the community hereafter. He had taken out in full the child death-rate for the five year periods up to 1915—he had not got them for the past five years—and the fall had been from 57 to 37, and it was still falling in the same way. Then he looked to see the result of the medical examination of school children notwithstanding this improvement, which, of course, had not made itself felt sufficiently as yet in the children who went to school. But he had found that, although they were developing medical service as energetically as they could, of the

first 750,000 children examined in the schools last year 40 per cent. were still found to be physically defective. The facilities for treatment had improved, and 69 per cent. of these had received treatment.

Position of the Voluntary Hospitals.

One of the subjects which must be the source of great anxiety was the position of the voluntary hospitals. They had under the Poor-law hospitals numbering more than half the hospitals of the country, and he had arranged to have these surveyed from a medical point of view, because it was necessary that not only should they be fully aware on the financial side of what they were doing, but they required a medical scientific survey of the hospital services which were available now and might be made more available under the Poor-law at the present time. Besides the assistance which had been given to the voluntary hospitals by the King Edward's Fund other proposals were being worked out. Those who, representing the voluntary hospitals, came to the Ministry and discussed the matters with them had, he thought, at first in mind that the Ministry was greedy to take hold of those institutions for some purpose or other of its own. They had enough responsibility in the administration of their services to save them from any temptation of that sort. Many of these institutions were pioneers of efficient service, and it would be a mistake of the first order to seek to interfere with that efficiency. Any scheme which the Ministry put forward would be designed to promote their public utility. In one other matter the Ministry had taken a step which would be recognised as essential—namely, in doing what it could to secure further provision for scientific and medical research, and the Treasury had made a grant for the service of £125,000, compared with less than £60,000 a few years ago. The paltry sum of £70,000, or thereabouts, by which they had increased the expenditure on medical research was a trifle as compared with the results which had already been achieved, and compared with expenditure in other directions which was far from being so fruitful. He had before him a long list, but he would only take two or three instances of the useful work which was being done by the grants given under this head. A grant was made with regard to the prevention of T.N.T. poison, for which they were paying several thousands pounds a week compensation. They only gave a few hundreds out of this research fund for the purpose, but it practically abolished T.N.T. poison. One of the age-long plagues of Egypt would have caused them immense expenditure just now had it not been for the work of research assisted out of this fund. Various grants under different headings were made at different times out of this research fund in connexion with antityphoid work. In the South African War the total strength of the British Army was about 530,000. The average ration strength was 208,000. In that war there were 57,684 cases of typhoid, and 8022 died. In the recent war the total strength of the forces would be under-estimated at 5,000,000, and the ration strength would be under-estimated at 1,200,000. Mainly as a result of research there were only throughout the whole war in the British forces 7423 cases of typhoid and 266 deaths.

More Money Needed for Medical Research.

Lieutenant-Colonel RAW congratulated the right honourable gentleman on the satisfactory and encouraging statement which he had made. There was no question that the general health of the community had undergone an extraordinary improvement during the last 25 years. He was very glad that the right honourable gentleman was asking for more money for medical research, because they felt, having very carefully to consider trying to do their best to eradicate such important diseases as influenza, scarlet fever, measles, and diphtheria, that they did not know sufficient about the causation of these diseases which produced such an enormous death-rate every year. They were all very proud of the voluntary hospitals. They had been the pride of this country and the envy of other countries, but we had now come to a time when these hospitals were unable, through insufficient financial support, to carry on the magnificent work which they had done for the last 300 or 400 years. There was a great class who were entirely overlooked in hospital accommodation, but they did not propose to accept charity, and they resented very much having to apply to the Poor-law. He hoped that the Minister of Health, in framing a broad and wise policy for the treatment of diseases in hospitals—because a great many of them could be treated only in hospitals—would, by combining and retaining the great voluntary hospitals, and in some way associating the great Poor-law infirmaries, many of which were quite empty and not required by Poor-law patients, be enabled to provide a national scheme of hospitals, which would be acceptable and beneficial to the whole nation. He was glad to hear the right honourable gentleman say that they would, at all costs, encourage the voluntary hospitals, and in no way interfere with their efficiency, but he was quite certain that financial support would have to be given to voluntary hospitals by the State if they were to continue

the excellent work which they had done for so long. He hoped that the Bradford experiment would be copied, so that hospitals might be provided on a national basis in which the patients would be able to pay for what they received.

In regard to the treatment of mental disorders, what was most required was that there should be facilities for the treatment of those persons afflicted with temporary mental disorder without their being certified as insane. If such a course were pursued, a very large number of people would be saved from drifting into hopeless insanity, and a very large amount of the accommodation in the asylums would not be needed. In this matter he hoped that there would be no association whatever with any lunacy authority, and that treatment would be obtainable in some hospitals totally unconnected with a lunatic asylum. The speech of the right honourable gentleman, with its outline of far-reaching schemes, had fully justified the formation of the Ministry.

Lieutenant-Colonel FREMANTLE joined in the congratulations to the Minister for the statement as to the way in which his Department in the first year after its creation had tackled the problems it had to face.

Progress was reported.

Statistics of Drunkenness in England and Wales.

Mr. HAYDAY asked the Secretary for the Home Department whether he could state what proportion the convictions for drunkenness bore to the population of Carlisle for each of the years 1914 to 1919; and what was the average proportion for all the county boroughs of England and Wales for the same years.—Sir JOHN BAIRD (Under Secretary for Home Affairs) replied: The figures desired are to be found in the Annual Volumes of Licensing Statistics and particularly in column 5 of Comparative Table B in each volume. They are as follows (the figures for the year 1919 being taken from the proof of the volume for that year which is in the press and not yet published):—

Proportion of Convictions for Drunkenness per 10,000 of Estimated Population in Carlisle and all County Boroughs respectively in Each of the Years 1914-19.

Year.	Carlisle.	All county boroughs, including London County.
1914	52'07	73'26
1915	52'45	54'92
1916	180'45	33'33
1917	60'59	19'18
1918	15'15	12'35
1919	12'96	23'75

For the years 1914, 1915, 1916, 1917, and 1918 the proportion to population is based on the estimated population for the middle of the year 1914. For 1919 the proportion is based on the estimated population for the middle of 1918. The estimated population of Carlisle for the middle of 1914 was 52,813; for the middle of 1918 it was 60,188.

Financial Position of the Voluntary Hospitals.

Major GODFREY PALMER asked the Prime Minister whether his attention had been called to the financial condition of the hospitals of the country; whether he was aware that some hospitals, owing to diminution in voluntary subscriptions, were in danger either of having to close entirely or much restrict their work; and whether he would cause immediate steps to be taken to deal with the matter.—Dr. ADDISON (Minister of Health) replied: I have for some time past been giving the most anxious consideration to the future of the voluntary hospitals. The situation in London has been relieved by the recent emergency distribution of £250,000 by the King Edward Fund, and the position of the provincial hospitals is generally less serious than in London. The question of State assistance raises many difficult issues, and I am anxious to avoid any precipitate measures which might prejudice the voluntary principle, to the maintenance of which I attach the greatest importance.

Protection of Young Persons Bill.

Mr. WIGNALL presented a Bill "to make further provision for the protection of persons under the age of 21 years from sexual immorality and from conduct akin thereto or connected therewith and to amend Sections 58 and 59 of the Children Act, 1908." The Bill was read a first time.

MONDAY, JULY 19TH.

Milk Imported from the Continent.

Captain Sir BEVILLE STANIER asked the Minister of Health if he could state what was being done to safeguard the consumers of the milk imported from Denmark and Holland; if the milk was being tested for purity and quality when it reached England; and were the farms inspected which produced the milk by their respective Governments.—Dr.

ADDISON replied: I understand that a few experimental consignments of sterilised milk were imported from Denmark in the earlier part of the year, but that the undertaking proved unremunerative. I have no information of milk imported from Holland, but in either case consignments would be subject to examination at the port of entry under the Unsound Food Regulations. Samples of the Danish milk have also been examined at the Ministry of Health. There is, I believe, a system of municipal inspection of dairy farms in Denmark and Holland.

Insurance of Agricultural Workers.

Captain REGINALD TERRELL asked the Minister of Health if he would state what had been the cost per cent. of the receipts from contributions of the working of the National Health Insurance scheme; what proportion in each case applied to workers engaged in agriculture; and the amount in the last year for which figures were available of claims paid to, and the contributions of, agricultural workers under the scheme.—Dr. ADDISON replied: With regard to the first part of the question, the question of working the National Health Insurance scheme by the general body of Approved Societies represents on the average about 12 per cent. With regard to the second and third parts of the question, the Department is not in possession of statistics as to the particulars asked for, whether in the case of agricultural workers or workers in other industries. The records required from the Approved Societies under National Health Insurance do not afford the desired information, because those bodies are not organised according to occupation.

Civilian Doctors and Income-tax.

Captain ELLIOT asked the Chancellor of the Exchequer if he would state why women doctors who were serving at home on whole-time contracts, but were told off to attend female units such as Queen Mary's Army Auxiliary Corps, had been refused the income-tax concession which was granted to other persons who were doing work of a military character; and if he would take the necessary steps to see that the matter shall be adjusted.—Mr. CHAMBERLAIN replied: Civilian doctors, whether men or women, detailed to attend units such as Queen Mary's Army Auxiliary Corps in this country cannot be regarded as entitled to the income-tax reliefs, which under Section 42 of the Income-tax Act, 1918, were allowed to sailors, soldiers, and others, who performed service of a naval or military character in connexion with the war.

Medical News.

UNIVERSITY OF OXFORD.—At examinations held recently the following candidates were successful:—

D.M.—F. L. Apperly, Lincoln (in absentia).
M.S.—N. A. Sprott, Christ Church.

UNIVERSITY OF MANCHESTER.—At examinations held recently the following candidates were successful:—

DEGREE OF B.Sc. IN PUBLIC HEALTH.

E. N. Ramsbottom, M.B., Ch.B.

DIPLOMA IN PUBLIC HEALTH.

Part II.—William Ash, M.B., B.S.; Sybil Bailey, M.B., Ch.B.; J. C. Beckitt, M.R.C.S., L.R.C.P.; Hilda K. Brade-Birke, M.B., Ch.B.; J. P. Charnock, M.B., Ch.B.; W. J. McIvor, M.B., Ch.B.; C. G. Magee, L.R.C.P.; Kathleen O'Donnell, M.B., Ch.B.; W. J. A. Quine, M.B., B.S.; Arnold Renshaw, M.D.; and L. S. Robertson, M.B., Ch.B.

UNIVERSITY OF BRISTOL.—At the examination held recently for the degree of M.D. the following candidate was successful:—

Oliver Charles Minty Davis, D.Sc., M.B., Ch.B.

UNIVERSITY OF GLASGOW.—The following degrees were conferred on July 19th:—

DOCTOR OF MEDICINE (M.D.).

James Gordon Wilson, M.B., Ch.B. (with commendation); Albert Barnes Hughes, M.B., C.M.; Donald MacKenzie MacRae, M.B., C.M.; and John Young, M.B., Ch.B.

BACHELOR OF MEDICINE AND BACHELOR OF SURGERY (M.B., Ch.B.)

With Honours.—John Wyllie and James Lorimer Halliday.

With Commendation.—William John Ferguson, Robert Dick

Gillespie, John Lang Anderson, Helen Frances Wingate,

Archibald Gordon Smith, Elsie Florence Farquharson, Margaret

Longwill Johnston, William John Payne, and Gilbert Paterson.

Ordinary Degrees.—Marion Bell Armstrong, James Baird, Annie

Barlow, Lillias Elizabeth Barr Buchanan, Alister Campbell,

James Gibson Campbell, Edith Chalmers, James Livingstone

Cowan, Edith Margaret Davidson, Simonne Denil (Mrs.

Thompson), Christian Melville Fleming, John Frew, Robert

MacInnes Gardner, James Alexander Moore Hall, Jack

Hurwich, Elizabeth Smith Inglis, Isabel Edgar Russell Jeffrey,

Anna Taylor Kellock, William Malcolm Knox, John Lavelle,

Jane Carrick MacDonald, Robert MacKintosh M'Kean,

Alexandrina Miller MacLennan, Peter M'Luskie, Joseph Patrick

M'Millan, Peter Macmurray, Charles Melville, Janet Dick

Montgomery, James Orr, James Paterson, Tejendra Nath Ray, Wilfrid Henry Scott, James Smart, David Croydon Smith, Mary Steven, Margaret Mavor Stuart, Helen Bruce Sutherland, James Nisbet Tennent, Jonathan Robson Turner, Mary Carswell Walker, Daniel May Watson, Mary Lyle Wilson, and Agnes Hart More Young.

QUEEN'S UNIVERSITY OF BELFAST.—Graduation day was on July 16th, when the following degrees in Medicine were conferred:—

M.D.—Edwin G. B. Calvert (gold medal), Edward B. C. Mayrs (gold medal), Robert Marshall (with distinction), Francis C. Carson, Robert M. Fraser, David Jamison, William S. Lloyd, Alexander M.D. M'Mullan, Abraham Porter, R. Lindsay Rea, and Edith Robinson.

M.Ch.—Henry P. Hall (gold medal), Henry P. Malcolm, George R. B. Purce, and R. Lindsay Rea.

M.B., B.Ch., B.A.O.—With Honours: Second Class: Frederick M. B. Allen, Victor M. Allison, Francis J. Boyd, Cawthorne L. Broomhead, R. Leslie Dodds, James S. J. Lee, James P. Martin, and Thomas G. W. Sloan.

Pass: John Alexander, Marion C. Alexander, Joseph F. Blaine, Crawford Blair, James S. Briggs, William Caithness, Robert J. E. Christie, Henry E. Coulter, Charles D. Crawford, William E. D. Crawford, Alexander Cromie, William F. Donaghy, John S. Dudgeon, John H. Dunn, Isaac Eban, Abraham H. Elliott, Patrick J. Flood, Thomas Gilfillan, Winifred E. Hadden, George Haddick, Patrick J. Honan, Thomas J. Hull, Lydia N. Humphries, Richard H. Hunter, Thomas R. V. Irwin, James W. Kernohan, Sydney W. T. Lee, Daniel V. M'Caughan, Phillip J. M'Garry, Henry M'Neill, Eveline F. Magee, Joseph Meban, Horatio N. Middleton, Elizabeth Michael, Phillip F. Mooney, Edward Moore, Helen M. Murnane, Joseph P. O'Kane, James J. M'C. O'Reilly, Joseph Reynolds, Samuel J. Stewart, George B. T. Story, William Verner, and James B. Wiley.

Diploma in Public Health.—Samuel Acheson, George Chesney, William Graham, James A. Harbison, George D. M'Iver, Thomas B. M'Kee, Herbert M'Master, James C. M'Millan, Robert C. M'Millan, Vincent Magee, George W. Rea, and Alexander M'M. W. Sergerdal.

There are now over 1100 students at the University, by far the largest faculty being the medical. The executive committee of the Better Equipment Fund has decided to sell the ground at New Forge, Belfast, and to give the proceeds of the sale to the University for acquiring a more suitable athletic field. The Cherryvale estate in the Newtownbreda district (where there is also an excellent dwelling-house which can be made a pavilion) has been bought for the sum of £20,000, and with alterations it can be made a good playing ground for football and cricket. The Senate at their last meeting (July 14th) appointed a committee to consider the question of the matriculations for entrance into the various faculties, the number of students in attendance at the faculties, and the number of those proceeding to an honours course. The committee was empowered to receive evidence from, or confer with, any body or any individual, either inside or outside the University, and to report to the Senate the result of the investigations.

Dr. Harvey Bateman, of Blackheath, has received from the King of the Belgians the Médaille du Roi Albert "avec rayure" in recognition of valued services rendered to the Belgian cause during the war.

Dr. F. W. Edridge-Green has been appointed a special examiner in colour-vision and eyesight by the Board of Trade.

Mr. Henry Kimpton announces the publication of the eighth edition of Dr. Hobart Amory Hare's "Diagnosis of Disease."

MIDDLESEX HOSPITAL NURSES' HOME.—The new home for nurses of the Middlesex Hospital, opened at Nos. 74, 76, 78, and 80, Gower-street, by Princess Alice on July 8th, is one of the best of its kind in London. Of the £13,000 required the sum of £8000 has been already collected, leaving £5000 to be raised to complete the equipment of this and of the other two homes for Middlesex nurses.

NATIONAL HOSPITAL, QUEEN-SQUARE.—Although several wards of the hospital have been closed through lack of funds, the whole of the out-patient department is working as usual.

GLASGOW ROYAL INFIRMARY: POST-GRADUATE CLASSES.—During the month of September a very complete course of post-graduate teaching will be conducted by the staff of this institution. Full details as to classes and emoluments are given in the advertisement columns.

1ST SCOTTISH GENERAL (TERRITORIAL) HOSPITAL: COMPENSATION FOR DAMAGE.—For damage done to Oldmill Poorhouse (late 1st Scottish General Hospital), caused by military occupation during the war, the Aberdeen Parish Council entered a claim against the War Office for £15,972. Lieutenant-Colonel Martin Cowan, valuator for the War Office, has assessed the damage at £12,606, and the Poorhouse Committee has recommended the Council to accept this sum. There is an additional £554 which has been transferred to another account, of which the Committee hope to receive payment.

Dr. C. Muthu, chief physician of the Mendip Hills Sanatorium, was entertained by old patients at dinner on July 16th in recognition of his completion of 21 years of sanatorium work. A presentation was made of an antique silver inkstand.

PAYING PATIENTS AT THE ROYAL PORTSMOUTH HOSPITAL.—At a meeting held on July 16th the committee decided to require payment, after August 1st, of 15s. per week for each adult in-patient and 7s. per week for those under 14 years of age, to cover the cost of maintenance. For those who are not in a position to pay these sums the committee will exercise its discretion and reduce the charge or waive it altogether. There is now an overdraft at the bank of £8500, which means a drain of about £10 per week on the income.

EDINBURGH UNIVERSITY EXTENSION.—On July 6th the foundation-stone of the most recent extension of Edinburgh University was laid by the King. The buildings, situated on the south side of the city near Blackford Hill, are to be known as the "King's Buildings," and that portion at present in course of erection is to be used for the accommodation of the chemistry department. The King and Queen, with Princess Mary, were received by the principal, Sir Alfred Ewing. After signing the University Album the King inspected the plans of the building and declared the foundation-stone to be well and truly laid. The Queen was then presented for the degree of Doctor of Laws.

SUMMER SCHOOL OF EUGENICS AND CIVICS.—The Eugenics Education Society is organising a summer school, dealing with the co-relation of eugenics and citizenship, at Herne Bay College, from Saturday, July 31st, to Saturday, August 14th. The inaugural address will be given by Professor Arthur Dendy, F.R.S., entitled "Evolution in Human Progress." Other evening public lectures include "The Press and Right Citizenship" and "The Treatment of Crime from a National Standpoint." The curriculum is arranged to deal with the problems of heredity, biology, and social psychology as they affect the lives of citizens in the present century. Among the lecturers are Dr. W. A. Potts (medical officer to the Birmingham Committee for the Care of the Mentally Defective), Mr. E. B. Turner, Dr. Otto May, and Dr. C. W. Ponder. The secretary of the school, Miss Constance Brown, may be addressed until July 30th at 11, Lincoln's Inn Fields, London, W.C. 2, after that at Herne Bay College, Kent.

SCHEME FOR A CENTRAL HOSPITAL IN ABERDEEN.—The scheme for centralisation on one site of the Aberdeen hospitals was advanced a stage further at a conference of the various public bodies interested in the proposal, which was held at the Town Hall on July 15th under the presidency of Lord Provost Meff. General approval was given to the scheme outlined by the Medico-Chirurgical Society, and it was resolved to appoint an executive committee for the purpose of inquiring into details and preparing an approved scheme for consideration at a subsequent conference. The executive committee consists of four representatives of each of the five bodies—the Medico-Chirurgical Society, the Royal Hospital for Sick Children, the Royal Infirmary, the University of Aberdeen, and the Town Council, along with Professor Matthew Hay, with powers to co-opt additional members. At a previous conference held on April 20th it was explained that the Medico-Chirurgical Society were of opinion that the requirements of the different hospitals could best be supplied by the provision of a common site, and that this would require to be sufficient for the needs of these institutions for the next 50 years. In the case of the Infirmary 500 to 600 beds would be required, and for the Sick Children's Hospital 150 to 200 beds. The departments of the University most closely associated with clinical work, such as those of medicine, surgery, bacteriology, and bio-chemistry, possibly the Incurable Hospital and the Ophthalmic Institution, would also be accommodated and provision made for the treatment of early mental cases and military patients. A dental school and a hostel for senior students might also be included. The advantages claimed for such a scheme are economy in management, more efficient service, combined training for nurses, up-to-date equipment, closer relations between the institutions concerned and the University, and possible post-graduate teaching.

THE DEATH OF SIR ALEXANDER DEMPSEY, M.D., J.P.—The death of a well-known and justly popular member of the medical profession, Sir Alexander Dempsey, occurred on July 18th. A county Antrim man, he was born in 1852, at Coldagh, Ballymoney, a son of the late Mr. Bernard Dempsey and a member of an able family. As a boy he was educated at St. Malachy's College, Belfast, and as a student he went to Queen's College, Galway, and to the Roman Catholic University Medical School, Dublin, graduating

M.D. of the Royal University of Ireland in 1874 and L.R.C.S. I. in the same year. He subsequently became a Fellow of the Royal College of Surgeons in Ireland. Immediately after graduating he started practice in Belfast, and made rapid headway in his profession, until at the time of his decease he was the principal Catholic doctor in Belfast and the north of Ireland. He took a great part in establishing the British Medical Association in Ulster, of which he was one of the first secretaries. He was an ex-President of the North of Ireland branch of the British Medical Association and of the Ulster Medical Society. In the erection and extension of the Mater Infirmorum Hospital he took the deepest interest, and at the time of his death he was consulting physician and acting gynaecologist to that institution. He was a member of the governing body of University College, Dublin, and an extern examiner in midwifery and gynaecology in the National University, of the Senate of which he was for a time a member. For the past two years he had been a member of the Senate of Queen's University, Belfast, and on several occasions he had held the office of university clinical lecturer in the Belfast School of Medicine. He was a Fellow of the Royal Society of Medicine and of the Royal Academy of Medicine in Ireland. In 1880 he was appointed a justice of the peace for Belfast, and in 1911 he was knighted. A man of great native shrewdness and of a most genial temperament, Sir Alexander Dempsey was a very hard worker and a most excellent medical opinion. He is survived by two sons, one a doctor, the other a member of the Irish Bar, and four daughters. His wife predeceased him. After a Requiem Mass at Holy Family Church, Newington-avenue, Belfast, on July 20th, he was interred in Milltown Cemetery, an immense number of friends and medical confrères being present.

LISTER MEMORIAL FUND.—At a public meeting held at the Mansion House in October, 1912, the following proposals for commemorating the work of Lord Lister were adopted:—

The placing of a memorial in Westminster Abbey, to take the form of a tablet with medallion and inscription.

The erection of a monument in a public place in London.

The establishment of an International Lister Memorial Fund for the advancement of surgery, from which either grants in aid of researches bearing on surgery or awards in recognition of distinguished contributions to surgical science should be made irrespective of nationality.

A meeting of the General Committee was held in the rooms of the Royal Society on July 19th last to receive and adopt the report of the Executive Committee appointed in 1912. The chairman, Sir Archibald Geikie, stated that the sums received in respect of subscriptions from the British Empire and foreign countries amounted to £11,846 5s. 10d. Expenses incurred in printing, stationery, postage, advertising, &c., amounted to £390. The report stated that delay had necessarily occurred in carrying out all the proposals adopted at the Mansion House meeting, but that a memorial tablet, executed by Sir Thomas Brock, had been unveiled in Westminster Abbey on Nov. 1st, 1915, and steps were being taken for the erection of a monument in a public place in London.

In order to carry out the scheme for the establishment of the International Lister Memorial Fund for the Advancement of Surgery the following proposals were adopted:—

(a) That out of the General Fund a sum of £500, together with a bronze medal, be awarded every three years, irrespective of nationality, in recognition of distinguished contributions to surgical science, the recipient being required to give an address in London under the auspices of the Royal College of Surgeons of England.

(b) That the award be made by a Committee constituted as follows: Two members nominated by the Royal Society, two members nominated by the Royal College of Surgeons of England, one member nominated by the Royal College of Surgeons in Ireland, one member nominated by the University of Edinburgh, one member nominated by the University of Glasgow.

(c) That any surplus income of the General Fund, after providing for the erection of a monument, and after defraying administrative expenses, be either devoted to the furtherance of surgical science by means of grants, or be invested to increase the capital of the Fund.

The continued carrying out of this scheme in future years will require the provision of some permanent and adequate machinery as the Lister Memorial Committee cannot, in view of its constitution, be itself permanent. The Committee, having ascertained that the Royal College of Surgeons of England would be prepared to become the trustees and administrators of the Lister Fund and to carry out its objects, subject to the above provisions of the scheme, authorised the Executive Committee to take such steps as may be necessary to give effect to this arrangement.

The subscription list is still open, and the honorary treasurer of the Fund is Sir W. Watson Cheyne, Bart., of whom donations may be addressed at the Royal Society, Burlington House, London, W. 1.

METROPOLITAN HOSPITAL SUNDAY FUND.—The total of the Hospital Sunday collection up to July 16th was £84,000.

GIFTS TO UNIVERSITIES.—Sir Jesse Boot has given £50,000 to the new Nottingham University scheme, £20,000 being for a chair of chemistry. Alderman Louis Samuel Cohen has given £15,000 to Liverpool University.

THE King of the Belgians has conferred upon Dr. Francis J. Allan, medical officer of health for Westminster, the Médaille du Roi Albert, in recognition of valued services rendered to the Belgian cause during the war.

THE medal of the Most Excellent Order of the British Empire has been conferred upon Dr. J. F. Williams, who is in practice at Camberwell-road, London, "for courage and devotion to duty on the occasion of an air raid in rescuing persons who had been buried in the cellar of a burning building."

A WAR MEMENTO FROM BRITISH TO AMERICAN SURGEONS.—At the suggestion of Sir Berkeley Moynihan, who has worked in collaboration with Sir Anthony Bowlby and Sir D'Arcy Power, a silver-gilt mace is to be presented to the American College of Surgeons (which includes Canada) as a memento of the work done in coöperation by American and British surgeons during the war. The mace is the work of Mr. Omar Ramsden, a well-known art metal worker, who has modelled the head of the mace on the lines of a surgeon's mortar dug up in a Salonika trench. The design includes maple leaves and American eagles, the badges of the British and American Army Medical Corps, and the serpents of Æsculapius, while the name is introduced of Philip Syng Physick (1768-1837), the father of American surgery, who was a pupil of John Hunter and an ex-house surgeon at St. George's Hospital. An inscription reads: "From the consulting surgeons of the British Armies to the American College of Surgeons in memory of mutual work and good fellowship in the Great War." The mace will be on view for a month at the Exhibition of Industrial Art, 217, Knightsbridge, S.W.

THE PHYSICS AND CHEMISTRY OF COLLOIDS.—The Faraday Society and the Physical Society of London are arranging to have a joint symposium and general discussion on this important subject next October. The subject will be introduced by a brief survey of the present position of colloidal physics and chemistry, and discussion will then arise on the following subdivisions of the subject: Emulsions and Emulsification; Physical Properties of Elastic Gels; Cataphoresis and Electro-endosmose; Precipitation in Disperse Systems; Glass and Pyrosols; Non-aqueous Systems. It is remarked that in spite of the importance of colloidal physics and chemistry in many branches of manufacture, and of the interest which the subject has aroused in recent years, much light remains to be thrown on the nature of the manufacturing processes in which colloids play a part. It is hoped that the discussion will focus attention on some of these problems, and that its result will be to indicate lines of advance and suggest further researches, and that it will be fruitful not only in helping to a fuller understanding of the laws of the colloidal state, but also in suggesting new applications for colloids in the laboratory and in the works. The exact date and place of meeting and further particulars will be announced later. In the meantime anyone desirous of using the opportunity of the discussion to bring forward experimental matter or theoretical considerations bearing on the above-mentioned branches of the subject is asked to communicate, as soon as possible, with the secretary of the Joint Committee, 10, Essex-street, London, W.C. 2.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

A Course of Twelve Lectures on Neurology, open to Students and Graduates of the London Hospital and other Schools—

TUESDAY, July 27th.—2 P.M., Lecture V.:—Dr. Riddoch: Disorder of Sensibility from Lesions of the Spinal Cord and Peripheral Nerves.

WEDNESDAY.—2 P.M., Lecture VI.:—Dr. Thompson: Sensory Disturbances of Spinal Origin.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, July 26th.—2 P.M., Mr. D. Armour: Operations. 2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

TUESDAY.—2.30 P.M., Mr. T. Gray: Operations. 2.30 P.M., Mr. Addison: Visit to Surgical Wards.

WEDNESDAY.—2 P.M., Mr. Addison: Operations. 2 P.M., Mr. D. Armour: Visit to Surgical Wards.

THURSDAY.—2 P.M., Mr. D. Armour: Operations. 2.30 P.M., Dr. A. Saunders: Visit to Medical Wards.

FRIDAY.—10 A.M., Dr. Robinson: Gynaecological Operations. 2.30 P.M., Mr. T. Gray: Operations.

Daily.—10 A.M., Ward Visits. 3 P.M., In-patient Clinics and Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, July 26th.—10.30 A.M., Mr. H. Evans: Diseases of the Urethra. 11.45 A.M., Dr. Banister: Malignant Disease of the Uterus. 2 P.M., Dr. Sundell: Chronic Pleurisy in Children. 4.30 P.M., Lecture.—Dr. Banister: Medico-legal Bearings of Gynaecological Practice.

TUESDAY.—10.30 A.M., Mr. Benians: Urine Analysis. 11.45 A.M., Mr. N. Fleming: Ophthalmoscopic Examination. 2 P.M., Mr. Hayton: Diseases of Accessory Sinuses of Nose. 4.30 P.M., Lecture.—Lt.-Col. R. H. Elliot: Affections of Eye due to Tropical Disease as seen in this Country since the War.

WEDNESDAY.—10.30 A.M., Dr. Alexander: Examination of Gastric Contents. 11.45 A.M., Mr. Carson: After-Treatment of Abdominal Operations (with complications). 2 P.M., Dr. M. Bahr: Cases of Tropical Disease as Occurring at Home. 4.30 P.M., Lecture.—Mr. J. W. T. Walker: A New Method of Prostatectomy and the Reasons for its Adoption.

THURSDAY.—10.30 A.M., Mr. Hayton: Otological Examination. 11.45 A.M., Mr. Gillespie: Surgical Pathology of Appendicitis and its Bearing on Treatment. 2 P.M., Dr. Metcalfe: Treatment by Ionic Medication. 4.30 P.M., Consultations (Surgical).

FRIDAY.—10.30 A.M., Mr. Benians: Puncture Fluids. 11.45 A.M., Mr. Gillespie: The Application of Plaster-of-Paris in Joint Conditions. 2 P.M., Dr. Alexander: Differential Diagnosis of Dyspeptic Conditions. 4.30 P.M., Lecture.—Mr. Carson: Diagnosis of Tumours of Great Intestine.

SATURDAY.—11 A.M., Dr. F. Thomson (at the N.E. Fever Hospital, St. Ann's-road, N.): Cases Illustrating the Early Diagnosis of Infectious Fevers.

Each Day.—3-4 P.M., General Hospital Practice.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, July 26th, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhœa by Electrolysis.

CANCER HOSPITAL, Fulham-road, S.W.

Clinical Lectures on the Diagnosis and Treatment of Cancer.

TUESDAY, July 27th.—4.30 P.M., Mr. C. Rowntree: Cancer of the Breast.

FRIDAY.—4.30 P.M., Dr. H. Robinson: Anæsthetics in Cancer Cases.

MANCHESTER FRENCH HOSPITAL POST-GRADUATE LECTURES, 24, Acomb-street (behind Whitworth Park).

THURSDAY, July 29th.—4.30 P.M., Dr. A. C. Magian: Chronic Uterine Complaints.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

DEVONALD, A., Captain, R.A.M.C. (T.F.), has been appointed Regimental Medical Officer to 4th Batt., K.S.L.I. (T.), and Medical Referee for Bridgnorth and District under the Ministry of Pensions.

GILMOUR, A., M.D. Edin., Medical Officer of Health and School Medical Officer of Hindley, Lancashire.

LAWSON, Dr., Medical Officer of Schools under the Bradford Education Committee.

Certifying Surgeons under the Factory and Workshop Acts: ROGERS, C. D., M.B., Ch.B. Edin. (Ellesmere); JONES, W. M., L.R.C.P. & S. Irel. (Llanfaircaereinion); ROBERTS, E. S., L.R.C.P. Lond., M.R.C.S. (Penygroes); MCLEAN, J. A., M.B., Ch.B. Glasg. (Buckhaven); KEAN, J., L.R.C.P. & S. Edin., L.F.P.S.G. (Forkhill); FYFE, W. W., M.D. Glasg. (Johnstone); BAMFORD, T., L.R.C.P. Lond., M.R.C.S. (Uttoxeter); FLOOD, J. W., M.B., B.Ch. Dub. (Liverpool, Central).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University.—Lecturer in Bacteriology. £500. Also Asst. in Path.

Bath, Royal United Hospital.—H.P. £150.

Birkenhead Borough Hospital.—Jun. H.S. £200.

Birmingham General Hospital.—H.P., H.S., and Cas. H.S. £100.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. £150.

Bolton Infirmary and Dispensary.—Female Sen. H.S. £300.

Bradford City Hospital, Leeds-road.—Asst. M.O. £350.

Bradford Royal Eye and Ear Hospital.—Aural S.

Bristol General Hospital.—P. and Asst. P.

Bristol Royal Infirmary.—Act. Hon. Asst. Obst. P. Also Res. Locum Tenens. 5 gs. a week.

Cardiff City Mental Hospital, Whitchurch, near Cardiff.—Sen. Asst. M.O. £550.

Cardiff, King Edward VII.'s Hospital.—H.S.'s. £200.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Res. M.O. £250. Also H.P. £100.

Colonial Service.—M.O.'s for West African Medical Staff, Government Service in Malaya, East African Protectorates, West Indies (including British Guiana), Fiji, and the Western Pacific, &c.

Croydon General Hospital.—Jun. H.S. £150.

Derby, Derbyshire Education Committee.—School M.O.'s. £550.

Dorchester, Dorset County Council.—Asst. County M.O. £500.

Dumfries and Galloway Royal Infirmary.—Res. H.S.

Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.

Halifax County Borough.—Female M.O. for Maternity and Child Welfare Clinics. £500.

Hereford County and City Mental Hospital.—Jun. Asst. M.O. £350.

Hove, Carr-Burton Memorial Hospital, Sackville-road.—Res. M.O. £250.

Huddersfield Royal Infirmary.—Sen. H.S. £250.

Huddersfield, Storthes Hall Asylum, Kirkburton.—Sen. Asst. M.O. £500.

Hull Royal Infirmary.—Asst. H.S. £150.

Johannesburg, South African Institute for Medical Research.—Asst. Bacteriologist. £800.

Leeds, City of.—Asst. M.O. for Maternity and Child Welfare. £500.

Leeds City Tuberculosis Sanatorium, Killingbeck.—Res. Asst. M.O. £300.

Leeds General Infirmary.—Res. Surg. O. £200.

Leith Hospital.—H.S. and H.P. £100.

London Temperance Hospital, Hampstead-road, N.W.—Asst. Res. M.O. £120.

Maidstone, Kent County Mental Hospital.—Jun. Asst. M.O. £300.

Manchester, Baguley Sanatorium for Tuberculosis.—Third Asst. Res. M.O. £300.

Manchester, City of.—M.O. £450 and war bonus of £307 15s. 6d.

Manchester, Monsall Fever Hospital.—Sec. Med. Asst. and Third Med. Asst. £300 each.

Manchester Royal Infirmary, Roby-street, Manchester.—Res. M.O. £200. Also H.P. £50 and £100.

Manchester Royal Infirmary.—Asst. Director, Clin. Lab. £300.

Miller General Hospital for South-East London, Greenwich, S.E.—Res. Cas. O. £150. Also H.S. £100.

Ministry of Pensions Hospital, Denmark-hill.—Visit. S. and Visit. P.

Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. Res. M.O. £200.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. Surg.

North St. Pancras School for Mothers, Queen's-crescent, N.W.—M.O. 1½ gs. per consultation.

Nottingham General Hospital.—Res. Cas. O. £300.

Plymouth Education Authority.—Dep. M.O.H. £600.

Plymouth, South Devon and East Cornwall Hospital.—H.P. £140.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Asst. Res. M.O. £60.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Anesth. £95. Also Path. £300.

Royal Institute of Public Health, Russell-square, W.C.—Sen. Demonstrator of Bacteriology.

Ryde, Royal Isle of Wight County Hospital.—Res. H.S. £250.

St. Bartholomew's Hospital.—S.

St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—H.S.

St. Thomas's Hospital Medical School, Albert Embankment, S.E.—Demonstrator of Anat. £400.

Sheffield, Children's Hospital, Western Bank.—H.S. £200.

Sheffield, East End Branch of the Children's Hospital.—H.S. £150.

Sheffield Royal Hospital.—Asst. Cas. O. £150.

Sheffield Royal Infirmary.—H.P. £150.

Shoreditch Metropolitan Borough.—Asst. M.O.H. £600.

Southampton, Free Eye Hospital.—Locum Tenens.

South London Hospital for Women, South Side, Clapham Common, S.W.—Female H.S. £100.

Stafford, Staffordshire General Infirmary.—H.S. £250.

Staffordshire Education Committee.—Practitioners under M.O.H. and Sch. M.O. £600.

Swansea General and Eye Hospital.—Jun. H.S. £200.

Taunton and Somerset Hospital.—Sen. and Jun. H.S.'s. £200 and £150 respectively.

Warrington Infirmary and Dispensary.—Jun. H.S. £200.

Windsor, King Edward VII. Hospital.—H.S. £200.

Worcestershire County Council.—Asst. County M.O.'s and Sch. Oculist. £500 each.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Yarmouth.

The Home Secretary gives notice that he proposes to appoint two additional Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of Lanark. Applications for the posts, for which surgical qualifications are required, should be addressed to the Under Secretary for Scotland, Scottish Office, Whitehall, S.W. 1, and should reach him not later than August 7th, 1920.

Births, Marriages, and Deaths.

BIRTHS.

ATTENBOROUGH.—On July 19th, at The Ridges, Farnborough, Hants, the wife of Dr. Wilfrid Attenborough, of a son.

BROWN.—On July 16th, at Welbeck-street, W., the wife of William Brown, M.A., M.D., D.Sc., of a daughter.

CHANDLER.—On July 12th, to Marjorie (née Raimes), wife of F. G. Chandler, M.A., M.D. Cantab., M.R.C.P., of 86, Harley-street and 4, Downshire Hill, Hampstead—a daughter.

DUDGEON.—On July 10th, at Cairo, the wife of Captain C. R. Dudgeon, R.A.M.C., of a son.

SHERWOOD.—On July 13th, at Eastbourne, to the wife of Douglas Sherwood, M.B., a son.

TUCKER.—On July 11th, at Park View, Pembury, the wife of S. A. Tucker, M.B., B.S. (late Captain, R.A.M.C.), of a daughter.

VARIAN.—On July 16th, to George Varian, M.D., and Hilda Varian, M.D., Thornborough House, Clarendon-road, Watford, Hertfordshire—a son.

MARRIAGES.

DOWNES—YOUNG.—On July 15th, at Park Church, Helensburgh, A. Drummond Downes, M.D., Ch.B., to Mary Angela Young, daughter of the late James Young and Mrs. Young, Rockmont, Helensburgh.

PENNY—KENWORTHY.—On July 17th, at Hoghton-street Baptist Church, Southport, by the Rev. Charles Brown, D.D. of London, and the Rev. J. A. Smallbone, Dr. Cyril John, youngest son of T. S. Penny, Esq., J.P., of Knowle, Taunton, to Dr. Muriel Mercer, eldest daughter of Dr. and Mrs. Kenworthy, of Kenworthy's Hydropathic, Southport, and Bentley Lodge, Parbold.

ROBINSON—STREDWICK.—On July 15th, at St. Clement Danes, Strand, Harold Shillito Robinson, M.R.C.S., L.R.C.P. Lond., to Vera Emily, only daughter of Mr. and Mrs. C. E. Stredwick, of Denham House, Epsom.

DEATHS.

ADAM.—On July 11th, at Liverpool, Edward Morison Adam, M.R.C.S., L.R.C.P., aged 39.

RHYS GRIFFITHS.—On July 13th, suddenly, Philip Rhys Griffiths, M.B., B.Ch., of Newport-road, Cardiff.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

THE GIANT NURSERY IN PARIS.—Our Paris Correspondent writes that the proposal for the transformation into a giant maternity home and crèche of the National Asylum at Charenton, noticed in THE LANCET of July 3rd, has met with such objection on the part of alienists that the Ministry of Hygiene has modified its decision. At present 500 mental patients occupy the asylum, which has accommodation for 1500. These 500 will remain in one wing of the vast building, and as they die out—the mortality-rate is admittedly high—their places will not be filled. From now on 1000 beds will be reserved for the Institute of Puericulture, providing accommodation for about that number of recently confined women, who will stay there with their infants for an average of two months. The number of these occupants will gradually increase in proportion as the others disappear.

DONATIONS AND BEQUESTS.—By the will of the late Mr. George Paxton, of Primrose Hill-road, N.W., manufacturing optician, the testator left the following bequests to hospitals, provided that the business relations between Messrs. Currie and Paxton and the hospitals still existed at the date of the will: £250 to the Royal Eye Hospital, St. George's Circus, S.E.; £200 each to the Central London Ophthalmic Hospital, the Western Ophthalmic Hospital, London, and the Bristol Eye Hospital; £150 to the Bristol Eye Dispensary; and £100 each to King's College Hospital, St. Thomas's Hospital, Middlesex Hospital, University College Hospital and the New Hospital for Women, London.

Notes, Short Comments, and Answers to Correspondents.

THE INCIDENCE OF FATAL RHEUMATIC HEART DISEASE IN BRISTOL, 1876-1913.¹

BY CAREY F. COOMBS, M.D., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN, BRISTOL GENERAL HOSPITAL; HONORARY CONSULTING PHYSICIAN FOR DISEASES OF THE HEART, MINISTRY OF PENSIONS, S.W. REGION.

IN the Annals of the Gloucestershire Medical Society¹ it is stated that on July 29th, 1789, Mr. Edward Jenner "favoured the Society with Remarks on a Disease of the Heart following Acute Rheumatism, illustrated by Dissections." At the same time Dr. David Pitcairn, who was physician to St. Bartholomew's Hospital from 1780 to 1793, was teaching—to quote Sir Norman Moore²—"that valvular disease was a frequent result of rheumatic fever." Since their day the cardiac lesions have come to be regarded more and more respectfully, while at the same time it has become clear that the joint lesions, though painful for a time, lead but seldom to any lasting impairment of function. The present-day view is, indeed, that carditis is the disease and polyarthritis one of the complications. To use Sir Norman Moore's³ words again: "Remembering the unwillingness of men and women to learn that they have diseases associated with the lungs or heart, I feel that 'heart fever,' which would be an appropriate term for a disease of which the most serious feature is endocarditis, would have little chance of coming into use instead of rheumatic fever. Were it not for this difficulty on the side of public opinion..... the term 'heart fever' might with advantage be adopted for that morbid condition in which endocarditis, transient arthritis, and raised temperature are always present." The instructed point of view, then, is that acute infective pancarditis is a specific disease complicated by polyarthritis, chorea, and so on.

This view is borne out by more minute inquiry into the nature of the disease. When I was a senior student at St. Mary's Hospital Dr. F. J. Poynton and Dr. A. Paine⁴ were publishing their papers on the "*Micrococcus rheumaticus*." I was able later⁵ to bring support to their views by showing that the tissues react in a certain definite way to the attack of this micro-organism; while in 1912 Dr. R. H. Miller, Dr. E. H. Kettle, and I⁶ found that the reactions provoked by experimental inoculation with the micrococcus were similar in essentials to those found in man.

Now, I assume that everyone is agreed upon the vital need for getting rid of rheumatic carditis and its crippling results. This can only be done by discovering first the means by which the organism gains its access to the cardiac tissues. For reasons I gave long ago,⁷ reasons apparent to all who study the subject, it seems clear that there is no question of continued reinfection of the host from without; the history of the disease is one of attack after attack, at intervals of months or years, extending over a decade or even more. The organism, therefore, is one that persists in the body for long periods. General considerations lead me to suppose that it is not in the cardiac tissues themselves, but at some point within the body, outside the circulation but with ready access to it, that it lives on from one outbreak to the next. Most likely it is closely related to the cocci that normally live on the mucous surfaces, especially those of the alimentary tract. Thence it passes into some intermediate tissue (probably the lymphoid aggregations), where its virulence is enhanced to the level of pathogenicity. From this in turn it escapes into the blood serum, under conditions predisposing to its increase in virulence, in small but repeated doses, and attacks the heart with irremediable results.

It has therefore seemed to me worth while to try and find out something about the external conditions that predispose to pathogenic action by this micro-organism. With this end in view I set out to explore the incidence of rheumatic heart disease in Bristol, in its relation to time and place. The difficulties of notification are very great, so I did not feel called upon to attack the problem in that way until I had tried a simpler method. Hospital figures, again, are so obviously incomplete as to furnish nothing except what would mislead. It did not seem possible to approach the matter except through the death registers of the city. This was undertaken, therefore, with the aid of a grant from the Research Committee of the University of Bristol Colston Society. I have also had the benefit of much advice from Dr. D. S. Davies, the medical officer of

health for Bristol; and the skilled and energetic assistance of his clerk, Mr. W. N. Brown, of whose help I cannot say too much. Indeed, with so much support I feel I ought to have accomplished far more than I have done.

The Method of Investigation Used.

The method adopted was to go through the death registers from 1876 to 1913 inclusive. Deaths from "acute rheumatism" and "rheumatic fever" were noted, also deaths from "rheumatic heart disease," "rheumatic pericarditis," and so on; and after much casting about I decided to include also all deaths from "pericarditis" and "endocarditis" occurring before the age of 25, unless the cause of the lesion was stated to be something other than rheumatic infection. (I chose this age after investigation of the age-incidence of rheumatic infection of the heart from hospital records.) I assume that practically all these deaths are due to the cardiac lesions, even where the certificate does not mention cardiac manifestations.

What I was trying to do was to make a list of deaths from active rheumatic infection of the heart. For the purpose of relating the onset of infection to locality and season it would be useless to include cases of post-rheumatic heart disease, since the course of many of these covers several decades and removes the death far from the time and place at which the infection first began. For the purpose of estimating the number of deaths attributable in each year to rheumatic infection of the heart and its after-effects I made lists for the years 1876, 1886, 1896, and 1906, which included deaths not only from the causes I have named but also from heart disease of all kinds before the age of 40 (excluding congenital lesions and ulcerative endocarditis). Anyone who has examined numbers of cases of cardiac disease post mortem will agree that practically all such cases are of the rheumatic type. Syphilis rarely kills by its cardiac lesions before 40. In these four years I have named, the average annual number of deaths from rheumatic heart disease as I have defined it, in all its stages, was 71 (73, if deaths from chorea be included) in an average population of 251,974. This, I feel sure, is an under-estimate, because many people do not die of post-rheumatic heart disease till after 40, and also because many cases of ulcerative endocarditis (not included in my total of 73) are due in part to a previous rheumatic infection of the valves. And even if the figure were correct for the mortality bills, they render no account of the progressive crippling of activity during the productive decades which is so deplorable a feature of the disease. As it is it seems to me serious enough to think that for every million city dwellers there should be 300 deaths from this disease each year; for I take it that Bristol is no worse off than other British cities in this respect. Curves of death-rate show that the death-rate from rheumatic heart disease is not dropping as sharply as the general death-rate. It is therefore a matter serious enough to justify a searching inquiry.

I am only too aware of my amateurish methods and unsatisfactory data. Before I had gone far into the death registers I saw that these records were not accurate enough to justify any minute deductions, yet it did seem to me that they might, on searching, reveal some features so striking as to give one a lead to further inquiry. I am afraid I cannot claim any very convincing results; but such as they are I bring them forward.

Seasonal Variation of Fatal Rheumatic Carditis.

The first point to which I ask your attention is that fatal rheumatic carditis appears to own a seasonal variation. The incidence is maximal in December and January, minimal in July and September. This corresponds broadly with rheumatic fever curves from the Scandinavian countries (Newsholme⁸). Comparison with charts of average rainfall and mean temperature seems to show some relation between high rheumatic incidence and low rainfall, and also high monthly mean temperature. In order to examine these possibilities in more detail a chart was prepared, by means of which we were able to compare, month by month, the rheumatic incidence with the rainfall and the mean temperature. There were six principal "spikes" upward in the rheumatic curve; in 1877, 1881, 1886, 1893, 1901, and 1911. The first two and the last two coincided with a low rainfall, but there was no clear relation to the temperature curve. Again, on six occasions the monthly rainfall exceeded 7 inches, and each occasion coincided with a low incidence of fatal rheumatic heart disease. Further, a sustained drop in the rainfall appeared to be followed by an increase of fatal carditis. The same fact has already been observed, in regard to rheumatic fever, by Sir A. Newsholme,⁹ and on much wider evidence. He explained it by saying that scanty rainfall caused a warm and dry subsoil, usually with an exceptionally low ground water. But a similar examination of the temperature curve fails to prove that it had any definite relation to the rheumatic incidence.

Geographical and Geological Inquiries.

The possible effect of locality was explored by marking the houses in which a death from rheumatic infection had occurred with a dot for each house, on a map of Bristol

¹ Read to the Thirty-first Congress of the Royal Sanitary Institute at Birmingham.

coloured to show the various geological formations. A street index of the deaths was also prepared. It must be confessed that neither of these plans brought to light anything definite. No epidemic was discovered, unless one takes note of a group of eight cases occurring within seven weeks (November and December, 1893) in a small area in the south-west centre of Bristol. During the same period only one other death was noted in the whole of the rest of the city. A search for "rheumatic houses" was fruitless. Only 11 houses were found in which more than one death from rheumatic infection had occurred; and in none of these had there been more than two such deaths. Moreover, in these instances examination of the facts did not warrant any belief in the house as a factor in the causation of the disease.

The map shows no relation between the geology of the city and the rheumatic incidence. Neither does it support the view that this disease is particularly fond of river valleys. The banks of the Avon and the Frome, with their ramifications, are not studded with dots in the map.

There are four areas in the city where 19, 20, or 21 dots are to be found within a square, the side of which is one-quarter mile in length. There is nothing in common between these areas except that they are all of them crowded with inhabitants. One of them is low down on a river bank, another is raised a little way above the river level by a sharp slope, a third is on one of the sharp inclines that rise steeply from the centre of the city, and the fourth is on the edge of Durdham Downs, on the upper limestone. As to density of population, it does not seem to me possible to prove that the high incidence of fatal rheumatic heart disease in these areas means anything more than that where more people live there also more people die. I have tried to find some relation between the incidence of carditis and the density of population by comparing the ascertained densities of the various registration areas with the rheumatic death-rates in those areas, but no such relation can be discovered.

Suggestions for Further Investigations.

Yet there is one last point of some significance. When he was preparing the charts Mr. Brown pointed out to me that the extensions of the city in 1897 and 1904 did not add much to the total numbers of deaths from rheumatic infection. Indeed, when we examine the curve of rheumatic death-rate we find that these inclusions coincided with a drop in the rate. When outer areas were added to the relatively congested centre a fall in the rheumatic death-rate took place. Is it not probable that the explanation may lie in the relatively rural and uncrowded character of the areas brought in? I think this is a possibility well worthy of exploration. This leads me to conclude with a brief outline of plans for further research. The present inquiry shows that rheumatic infection of the heart is killing 70 or 80 people every year in Bristol, to say nothing of the decade or more of lessened efficiency that precedes a majority of those deaths. The mortality figures, imperfect though they are, do not point to any great natural fall in the incidence of this disease. They show that when the city has been "countrified" by inclusion of partially rural areas the death-rate from this disease has fallen. The winter rise in its seasonal curve is at the most only partially explained by reference to climatic conditions. Is it not possible that there is an economic factor in the causation of this infection?

To put such a question is one thing; to answer it is another. But it does appear to me that we ought to try. Data as to the incidence of rheumatic carditis must be collected from an area wide enough to include rural as well as urban districts. The first difficulty is to determine what we are to regard as rheumatic carditis. I do not at present know of any specific test, and we must rely on the judgment of the practitioners in the area selected, aided by some kind of definition of the cases to be noted, and, if possible, by referees with special knowledge of the disease for doubtful cases.

I think some little time should be spent in explaining the nature of the investigation, so as to enlist the enthusiastic help of the medical men concerned. For the reports which they would be asked to make adequate payment must, of course, be arranged. I do not know of any area more suitable from the economic point of view than that surrounding Bristol, and I hope it may be possible to organise the inquiry in that area. It will take two or three years to get ready for it, but I believe my Bristol colleagues will help, while so far as Gloucestershire is concerned it seems to me that the medical organisation which we all associate with the name of Dr. Middleton Martin will greatly facilitate these preparations. And I must confess that it seems to me peculiarly fitting that we should look for a lead in this matter to the general practitioners of the very county in which that prince of general practitioners and clinical observers, Edward Jenner, read to the Medico-Convivial Society of Gloucestershire in the parlour of the Fleece Inn at Rodborough, "Remarks on a Disease of the Heart following

Acute Rheumatism," which entitle him to claim with Pitcairn the honour of initiating the campaign that we are now taking up against this crippling and destructive infection.

PESTILENCE IN THE NEAR EAST.

UNDER the title of "Health Conditions in Eastern Europe: Typhus a Serious Menace," Major F. Norman White, I.M.S., C.I.E., delivered an important lecture under the auspices of the Chadwick Trust at the Surveyors' Institution, Gt. George-street, Westminster, on July 15th, Sir William J. Collins being in the chair. Major White, who is a medical officer under the Ministry of Health, has just returned from Eastern Europe, where, as Commissioner for the Typhus Commission of the League of Nations, he has been visiting the infected areas. The countries chiefly considered were Latvia, Esthonia, Lithuania, Poland, and the Ukraine, all situated on the border of Soviet Russia.

The Conditions in Russia.

With regard to Russia, said the lecturer, detailed information was lacking, but it was known that health conditions were appalling, and the incidence of typhus and other epidemic diseases had been exceedingly high. The deplorable situation in Russia was one of the chief contributory causes of the unhealthy conditions now prevailing in the countries under consideration. It was, however, difficult to appraise the degree of credence that could be awarded to such vital statistics as emanated from Russia in existing circumstances. He had been informed by Dr. Haden Guest, who had just returned from a mission to Russia, that during 1918-19-20 Russia and Siberia had been swept from end-to-end by typhus fever and that scarcely a town or village escaped. It was stated that some 50 per cent. of the doctors attendant on typhus fever patients had died of the disease. Recent cables stated that cholera is widespread in Southern Russia and is causing there a very high mortality.

Poland's Handicap.

Of the states involved Poland was the largest and the conditions there would apply almost equally to the neighbouring states. Through Poland passed most of the main lines of communication by road and rail connecting Russia with Western Europe, consequently the efficiency of Poland's organisation was a matter of very direct concern to Central and Western Europe. Poland, too, had suffered more from epidemic diseases than had her smaller neighbours and her task was the most difficult, though similar in kind. Poland's strenuous efforts to work out her own sanitary salvation in spite of overwhelmingly important preoccupations entitled her to special consideration. Poland was a densely populated country for its degree of industrial development, with 250 persons to the square mile. Sanitary conditions, even before the war, were in a deplorably backward condition. Only three towns of what was now Poland had anything like an up-to-date water-supply, and in Warsaw alone was there any modern system of sewage disposal. Facilities for cleanliness in the form of public baths and other conveniences were extremely deficient. Scavenging was inefficiently carried out. The standard of personal cleanliness was low, especially in the poor Jewish quarters of the towns. The death-rate was very high, though coincidentally a very high birth-rate (40.6 per 1000 in 1910) was probably a marked feature of the vital statistics. Tuberculosis was prevalent in the towns. The infantile mortality-rate was excessive. The deaths of children under one year of age in the Austrian part of Poland during the quinquennium 1906-10 averaged 205 per 1000 births. Epidemics closely followed the outbreak of hostilities. In 1915 in a small part of Galicia that was free from Russian occupation there were 19,000 cases of typhoid fever, 11,000 of dysentery, 8000 of typhus, 21,000 of small-pox, and 29,000 cases of cholera. As the war progressed affairs became progressively worse. In 1917 the deaths outnumbered the births in every town and district of Poland. In that year the tuberculosis death-rate in Warsaw was 7.3 per 1000, and in Lodz 11 per 1000. Infantile mortality rates were higher than ever, and such diseases as rickets were said to be increasingly prevalent.

Typhus, Checked and Unchecked.

A serious epidemic of typhus still raged, more especially in Eastern Galicia, the conditions for its spread being particularly favourable owing to the devastation caused by war and consequent overcrowding. In Congress Poland 325,000 houses had been destroyed, and in Galicia 438,000. Soap, fuel, and other essentials to cleanliness were unobtainable in most parts, and elsewhere difficult and costly to obtain; changes of clothing were difficult to get; lousiness among the poor population was almost universal; dirt and

squalor characterised the poor quarters of the towns; privation, want, and disease had diminished the vitality and lowered the resistance to infection of large masses of the population and produced a condition of apathy that would be difficult to overcome. Over and above all this there had been a constant and continuous stream of civil and military refugees crossing the Polish borders, many of them infected with typhus contracted in Russia; the vast majority of them were infested with lice and other vermin. Between November, 1918, and January, 1920, 653,000 prisoners of war of all nationalities passed westwards over the Polish frontier, as well as 627,000 emigrants returning to Poland. These were all registered in the various posts through which they passed. In addition, some large numbers of refugees from the neighbouring war zone crossed the border. This primary source of infection of many diseases continued to operate. It was estimated that there were still a million persons in Russia waiting to be repatriated, and refugees and prisoners of war continued to increase the dangers of infection. All these unfortunate people came from areas where disease was already out of hand. The cessation of hostilities between Poland and Russia would not mean an immediate amelioration of these conditions and resumption of cross-frontier traffic, and trade would have its attendant public health dangers. In 1919 there were no less than 231,000 cases of typhus notified in Congress Poland and Galicia, and probably at least half the total number of actual cases were unnotified. During a short tour which he (the lecturer) made last month in Eastern Galicia scarcely a town or village was free from typhus, and this at a time of year when conditions should have begun to improve. There were good grounds for regarding the outlook for Galicia next winter as serious in the extreme.

The persistence of typhus was, perhaps, a better index of insanitary conditions than is furnished by any disease. Where typhus abounded there most other epidemic diseases could flourish. In temperate climates, if conditions were such that typhus could not flourish, the incidence of most other communicable diseases was likely to be low. Dangerous foci of epidemic disease were of more than local importance; mankind could not with impunity suffer plague spots to persist, especially when situated in the midst of civilised Europe. Persistence of present conditions would entail a never-ceasing vigilance on the part of the health authorities of more happily placed countries such as our own, and even then the disease might break through our barriers. This was well illustrated by the serious epidemic in Holland, a peaceful, well-fed, and prosperous country, in 1918. The menace of typhus was a very real one.

Interaction of Disease and Social Unrest.

The persistence of typhus and other epidemic diseases in Poland and adjacent countries was in part an economic question. High prices, scarcity of food, underfeeding, overcrowding, were all factors that no epidemiologist could overlook. Undue prevalence of disease might in its turn be directly responsible for such economic conditions as prevailed in Eastern Europe, and was a factor of great moment in keeping the populations in a state of constant ferment. Improved economic conditions were almost impossible in existing health conditions. At the root of inefficient labour, deficient output, and industrial unrest there often lay a removable pathological cause whose consideration would lie within the legitimate scope of the public health of to-day. Prevalence of disease might likewise play no insignificant part in the production of such social unrest as at present characterised Russia. A return to more normal conditions—political, social, and economic—on the continent of Europe had little likelihood of being attained unless and until the health conditions underwent substantial ameliorations. Excessive prevalence of disease, too, had a markedly deleterious effect on the physique and development, both physical and mental, of the rising generation, while education was retarded. All these things were factors in unrest.

Present and Future Needs.

The League of Nations had recently created a Typhus Commission, whose function it would be to aid the Eastern countries in their great health task. It was hoped that two million sterling would be raised, the minimum amount necessary to render adequate help. In addition the League of Red Cross Societies was issuing an urgent appeal to supplement the work that was already being done by voluntary societies. It was very desirable that adequate funds should be forthcoming sufficiently soon to enable next winter's epidemic of typhus to be forestalled. In the Baltic States conditions in regard to typhus fever had somewhat improved; Finland appeared to be practically free from the disease. In Esthonia there were less than 200 cases, in Latvia 879, and in Lithuania 590. In these countries American Red Cross doctors were rendering valuable aid in controlling the disease. There was very little typhus at present in Roumania, and it was chiefly confined to the Northern districts bordering on Galicia, the Ukraine,

Bessarabia, and Maramures. In the Ukraine conditions had been very bad, and from 10 to 15 per cent. of the population had succumbed to typhus or relapsing fever. But generally the outlook was grave enough to call for immediate palliative measures. The lecturer's recent visit to Poland on behalf of the League of Nations had been made with the primary object of ascertaining how foreign countries could best supplement Poland's efforts in the anti-typhus campaign. The best possible use was already being made of the very inadequate resources, and the energy displayed by the Chief Epidemic Commissary in Galicia was worthy of admiration. The plan adopted by the Polish Ministry of Health included arrangements for the establishment of a series of quarantine and observation stations along the Eastern border of all the main roads and railways, where refugees and emigrants could be cleansed, fed, and clothed, each station having a hospital attached to it; the establishment of hospitals in each district for the reception of cases of infectious diseases, also the establishment of corps to clean up infected houses and villages; and the installation in towns and villages of bathing, cleansing, and disinfecting plants. Essential, however, as this scheme was in all its details, it was quite beyond the resources of the Polish Government at the present time. Additional hospital material for at least 20,000 beds with full equipment was needed at once, disinfecting apparatus in large amount was required, clothing for refugees was an indispensable necessity, and would entail a very large expense. The rags of the refugees fell to pieces if attempts were made to rid them of vermin, and during the next twelve months something like two million shirts and a proportionate amount of other clothing would be called for. Soap in almost unlimited amounts was required, and certain foodstuffs for the quarantine stations and hospitals were needed, together with transport vehicles. Doctors and nurses were required to supplement the work of the insufficient and overworked Polish medical personnel. Only adequate help from more fortunately placed countries would rid Europe from what was a very real peril.

In concluding, the lecturer paid a warm tribute to the work of the American Red Cross, the "Hoover" Organisation, the European Children's Relief Fund, which during the past few months had provided 1,300,000 persons with one meal a day, the Jewish American Joint Distribution Committee, the National Alliance of American Poles, the Society of Friends, the American Typhus Relief Expedition, the Polish Red Cross, the British Red Cross, and the League of Red Cross Societies.

PUBLIC HEALTH IN TASMANIA, 1918-19.

SOME important advances in public health legislation in Tasmania were made by the passing of the Hospitals Act (1918), the Midwives Act (1918), and an Amendment to the Public Health (Venereal Diseases) Act of 1917. By this last measure a medical practitioner who has reason to believe that a patient suffering from venereal disease intends to contract marriage is directed to notify his belief to the chief health officer, who shall thereupon inform the other party to the proposed marriage or the parent or guardian of such party. No liability for defamation shall be incurred by a practitioner making such notification in good faith. Dr. A. H. Clarke, the acting chief health officer, considers that the same privilege should be extended to practitioners making similar communications in good faith in the case, e.g., of men with syphilitic sores on their hands who have the handling of food for human consumption. It is satisfactory to learn that the venereal disease notifications, numbering 366, during the 12 months from July, 1918, to June, 1919 (of which 307 were for gonorrhoea), were 77 less than in the 12 months preceding. Dr. Clarke points out, however, that "until facilities are provided in every important centre of the State for the treatment of persons suffering from venereal disease it will not be possible to grapple with this important health problem." Diphtheria was prevalent (737 cases and 17 deaths), but evidently in a very mild form; about a quarter of the cases occurred in Launceston. There were 189 cases of phthisis and 144 of typhoid fever throughout the State and no other disease prevalence of any importance. Dr. Clarke describes the scheme of operations that was decided on in the event of influenza appearing in epidemic form in Tasmania, but happily no cases had occurred up to the date of this report (August, 1919).

THE GOLDEN RULE AS APPLIED TO TUBERCLE.

GIVING evidence on Feb. 3rd, 4th, and 5th, at Washington, before the Committee on Public Buildings and Grounds of the House of Representatives, Dr. E. R. Baldwin emphasised the need for providing attractive, as well as hygienic, accommodation for consumptives. "..... Whatever buildings the United States Government constructs, my advice would be, as a tuberculosis specialist, and as a patient myself, not to put the tuberculosis soldier in a place you would not be willing to go to yourself. That is the crux of the thing."

TOXIC IDIOPATHIES:

THE RELATIONSHIP BETWEEN HAY AND OTHER POLLEN
FEVERS, ANIMAL ASTHMAS, FOOD IDIOSYNCRASIES,
BRONCHIAL AND SPASMODIC ASTHMAS, ETC.

Delivered at the Royal Society of Medicine

BY J. FREEMAN, M.D., B.Ch.Oxon.,

DIRECTOR OF THE DEPARTMENT OF CLINICAL BACTERIOLOGY OF
ST. MARY'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—There are a number of affections, apparently dissimilar, which for their study and treatment should be classed together; I have done so by calling them by the group name "toxic idiopathies." I hope to justify this name to you to-day; and I shall be able to make myself clearer if I work through my subject in the order in which the various problems actually occurred to me. This arrangement will give the advantage of proceeding from the better to the less understood parts of the subject.

HAY FEVER.

Hay fever is one of these toxic idiopathies. Leonard Noon started work on this ten years ago; after only a few months he fell ill, and I have been working at the subject since then. It will be convenient to take hay fever as our type, but it will not be necessary, and we should not have time enough, to discuss hay fever exhaustively. All we need do is to tabulate the facts which serve to link it up with the other toxic idiopathies to be discussed later.

I. *Causal agent.*—Grass pollen stands in much the same causal relationship to hay fever that the tubercle bacillus holds in tuberculosis. In this sense pollen—and only grass pollen—causes hay fever; it does so whenever it comes into contact with the tissues of the susceptible person. It can do this at any time of the year, but only does so in nature when the grasses are producing pollen. The incidence of the disease shown in Diagram 1 exactly corresponds to the period of grass pollen production. Experimentally, however, the disease may be produced at any time of year by pollen which has been kept in a dry state.

DIAGRAM 1.—Curve showing case incidence of hay fever, compiled from some 300-400 cases studied in the last 10 years.

II. *Spontaneous local symptoms.*—Symptoms are experienced at every point where this pollen can get to work on the tissues of hay fever sufferers. As grass pollen is adapted for its purpose of cross-fertilisation by being extremely easily air-borne (it will even float in air from Norway to Yorkshire, as Blackley showed by his ingenious kite experiments), it is always present in the atmosphere during the grass flowering season, except when it has recently been precipitated by rain. It will, therefore, come in contact with the external surface of the body; but the skin of most pollen-sensitive persons is too thick, too much covered by the dead horny layer of the epithelium, to permit any biological reaction

except at the conjunctiva or the mucous membrane of the air-passages. Here, therefore, the local symptoms of hay fever are produced in greatest intensity: inflammation, irritation, oedema, coryza, lacrimation, and sneezing; but thin-skinned persons (chiefly women and children) may suffer itching, erythema, and even urticarial weals over the skin of the face and neck, and some very thin-skinned persons experience this over the entire body.

III. *Artificial local symptoms.*—The natural symptoms can be reproduced at any time of the year, either with dry pollen, or more mercifully with a carefully diluted watery extract of the pollen. Diagram 2 shows the effect on the eye of a hay fever patient, and this ophthlmo-reaction will either: (1) serve as a diagnostic test at any time of the year of the pollen susceptibility which characterises hay fever; or (2) if the reaction is conducted with known dilutions of the pollen extract an estimate can be made of the degree of the susceptibility of that patient.

That the whole body is sensitive, and not merely the eyes, nose, and throat, is shown conclusively by producing reactions in abnormal sites. Dunbar placed pollen in the rectum and got the symptoms. More conveniently, one or two scratches through the horny layer of the epidermis will permit the pollen to act on the living tissues at any point of the body surface. Diagram 3 shows the effect produced by pollen or by a watery extract of pollen on the scratched skin; and such a cutaneo-reaction can, like the ophthlmo-reaction, be used either for diagnosis or quantitatively for measuring the degree of sensitiveness.

Pollen experimentally swallowed with the food gives rise to nausea, vomiting, a feeling of indigestion, and diarrhoea. As this will be of special interest when we consider the toxic idiopathies connected with food sensitiveness, I may, perhaps, here give a sample experiment.

A young man in my hay fever clinic at St. Mary's Hospital recognised in someone who came to see me a brother-in-arms from the same battalion in the war. They readily agreed to split a bottle of beer surreptitiously doctored with pollen. The normal man drank fair but experienced no sensations, but the hay fever patient had marked nausea for four hours, especially on exercise, and, what was most unusual for him, distinct looseness of the bowels for a day or two.

IV. *Constitutional or distant effects* are also produced by the irritant: lassitude, depression, irritability, headaches, general urticaria or oedema, and asthma. Such general symptoms are produced by the natural disease and also by the experimental administrations of pollen at abnormal sites—e.g., by large hypodermic doses (large, that is, from the point of view of therapeutics or prophylaxis), or by incautiously severe skin reactions, or by the experimental ingestion of pollen in the food.¹

V. The *specificity* is very marked. None but hay fever sufferers will ever react to grass pollen, and grass pollen produces no effect on normal persons.

VI. The *commencement of attacks* may seem to the patient to be due to many things. When, but only when, grass pollen is in contact with the tissues (normally, i.e., when it is in the air during the times of incidence shown in Diagram 1) the hay fever symptoms may be precipitated by a number of diverse stimuli—e.g., by any mechanical irritant, by any strong smell, "even the smell of my dinner," any strong light, a change from cold to hot surroundings (and vice versa), by any strong emotion, like the shock of bad news, or by suggestion. These statements are admittedly given without proof or explanation; perhaps the last of this somewhat indigestible list may be illustrated by comparison with seasickness. Vomiting may often be promptly induced, but only on board ship, by people speaking of sea-sickness or by someone imitating a rolling motion; in the same way sniffing at an artificial rose or merely listening to a vivid

¹ Such experimental contact with pollen in abnormal situations may also produce the eye, nose, and throat symptoms of the natural disease. This would certainly seem to denote local sensitisation, but this does not concern our argument here.

description of a sunny field on a hot still day may produce, but only in the hay fever season, fits of sneezing or the ophthalmic-reaction shown in Diagram 2.

All these, as it were, "detonations" of hay fever symptoms may profitably be borne in mind when considering some immediate "causes" of symptoms (e.g., of asthma) in the other toxic idiopathies.

VII. *Passive immunisation* may be produced against

with the ophthalmic-reaction their effect on his patients; one can also use the cutaneous-reaction. The two curves in Diagram 4 show the changes in sensitiveness which follow the administration of a pollen vaccine. One is measured by the ophthalmic- and the other by the cutaneous-reaction method.

Though there are, of course, failures to deplore, yet from 80 to 90 per cent. of hay fever cases inoculated

DIAGRAM 2.—Ophthalmic-reaction for diagnosing hay fever. First very dilute extracts of grass pollen, then progressively stronger extracts, are dropped on the eyeball of the patient till a slight itching and a faint redness develops at the inner canthus of the eye. The eye to the left in this diagram shows the normal condition; the other eye shows a definite hay fever reaction. The reaction should take about three minutes to develop.

hay fever—that is to say, one may immunise a horse or other animal with grass pollen, and the serum of such an animal will give some degree of alleviation from the symptoms. This work was carried out by Dunbar, of Hamburg, the serum being known as pollantin; and it

during the last ten years have been well pleased to have been so treated, and with many of these the results are really striking.

For three months in every year a man had to go to sea because of hay fever, and ruined his business in consequence.

One year, through pressure of work, he risked staying in London, and, as a result, spent two months in a dark room with his body packed round with hot-water bottles to stop the shivering fits and his head packed with ice-bags, the conjunctiva skinning off his eyeballs and his lungs gasping for breath. Since his inoculation treatment began nine years ago that man has been at work through each summer, and last year told me that for half an hour one afternoon he "felt a slight annoyance from the old enemy."

IX. *Heredity* is strongly marked in hay fever, as Diagrams 5 and 6 show clearly enough; the monogram made by compounding the letters H and F indicates in this and the succeeding genealogical tables the incidence of hay fever. (In Diagram 6, where H is added, the individual had horse asthma as well as hay fever; the significance of this is mentioned later.) In going over my records of cases last summer I was able to pick out some 200 well-marked examples of heredity, any one of which could have served for my argument. Heredity, we shall find subsequently, is a link which closely binds together the different toxic idiopathies.

For portability we may summarise the foregoing characteristics of our typical toxic idiopathy as: (a) the *symptom-complex* both of the natural and also of the artificial disease; (b) the *specificity* both of the irritant for that particular patient and of the patient for that particular irritant; and (c) *heredity*.

DIAGRAM 3.—Cutaneous-reaction for diagnosing hay fever. Some convenient portion of the skin is scratched to remove the dead, horny layers and then a watery extract of grass pollen is placed thereon. The diagram shows to the left no reaction; in the centre a minimal but definite reaction; to the right a severer reaction produced by a stronger extract. This reaction takes from 10 to 15 minutes to develop.

is important to note that pollantin will give definite relief, though this is so slight and transient that the effect is negligible if the case is at all severe.

VIII. *Active immunisation* with a vaccine made from the grass pollen works well, both for prophylaxis and for therapeutics. Noon selected his doses by tracing

Other pollens than grass pollen produce reactions, each acting on the eye or on the skin of those sensitive to that particular pollen, causing reactions precisely like those shown in Diagrams 2 and 3. Also these pollen sensitivenesses tend to run in hay-fever tainted families—that is to say, they will either affect sufferers from hay fever or their close relatives. Diagram 7 shows in tabular form the response which a number of hay

There is much talk in America and elsewhere of pollen fevers caused by other trees and plants, but time will show if they are any of them of much importance. As we have seen, every one of the pollens produces toxic effects upon susceptible people, and it is merely a botanical accident as to whether the particular toxic idiopathy in question makes serious trouble for humanity or not.

ANIMAL ASTHMAS.

Eight or nine years ago hay fever seemed to stand alone, but Dunbar told me that the horse sensitiveness known as "horse asthma" was an occasional symptom, or at least was never found, except associated with hay fever; this, it now appears, is not always true, but why it should frequently be so will be shown when discussing heredity presently. The irritant is usually airborne, and so the local symptoms are similar to those of hay fever; the victims get red eyes, a running nose, much sneezing, and a tickling throat when near horses, and constitutional symptoms such as are found in hay fever. All these symptoms are produced, especially if the animals are lathering freely or in an ill-ventilated stable. With "horse substance" in place of grass pollen one can carry out parallel reactions to those used for diagnosing or estimating the sensitiveness to hay fever, and Diagrams 2 and 3 would serve equally well for a horse-asthma reaction. Normally it is the horse dandruff (i.e., the debris which comes off on a curry-comb) which picks out for us the horse asthmatic, but almost any part of the horse will provoke the reaction—the flesh, the serum, the urine, the faeces, or the mucous discharge from the nose. Furthermore, other members of the horse tribe share with horses this power to react with a horse-sensitive person, as Diagram 8 shows.

A couple of examples of horse asthma will bring out most of the characteristics and make it a definite disease-entity for us.

An officer in the Horse Guards developed horse asthma and so had to resign his commission; also he had to give up hunting and avoid hunting men until they had changed their clothes and washed after riding. He quickly learned to avoid the trouble, but once, when shooting in Scotland, put on his mackintosh because it was raining. Almost immediately he began to have bad asthma, could not put a gun to his shoulder all day and, on returning to the house, found he had put on the mackintosh belonging to a horsey man, who always wore it when on horseback or kept it rolled up on the horse's withers. The same patient when stopping in a house where a case of diphtheria had occurred received from the local practitioner a dose of antidiphtheritic

DIAGRAMS 4A and 4B.—The two curves show the effects on the sensitiveness of a hay fever patient to grass pollen after hypodermic inoculation of a grass pollen vaccine. The upper curve is measured by the ophthalmic reaction, the lower curve by the cutaneous reaction. The vertical lines show days after the dose.

fever patients and two relatives show when tested with grass pollen and a random collection of 25 other pollens. From this we may judge that practically every pollen one cares to test will react on some person or another with the hay fever taint; but note how capricious is the selectiveness of the different pollens, reacting with some hay-fever tainted persons strongly, with other persons reacting only weakly, and with others again not at all. One must regard each as being the irritant of a separate toxic idiopathy; each is a potential cause of a fever parallel to hay fever.

How, then, can one say that, in England at any rate, grass pollen causes the only pollen fever which counts? Because in this country grass pollen alone fulfils all the three essentials for a considerable disease. These are: (1) production in sufficient amount; (2) capacity for producing a strong reaction; and (3) dissemination by light wind. For example, many varieties of daisy pollen are frequently strongly toxic and produced in considerable quantities, but this pollen only flies yards where the grass pollen flies miles. Again, the pollen of the firs and pines is produced in large quantities, and is fairly easily borne on light airs, but proves to be only slightly toxic for most persons with the pollen-sensitive taint (Diagram 5 chances to over-represent the toxicity of the coniferæ). In America, however, there is an indigenous race of composites which provoke an intense reaction in those who happen to be susceptible, and, in addition, the pollen is produced in large quantities and is very easily wind-borne. As a result, in America there are two pollen fevers, one occurring at the time of the flowering of these composites—viz., in August, September, and October—which is known as the American autumn fever, and another at the time of the flowering of the grass, which happens about the same time as in Europe, and is, therefore, known as the June fever. It is this latter alone which is rightly called hay fever.

serum which, of course, is obtained from horses. As a consequence they sat up with him all night, and were very relieved that he survived. He finds London nowadays very much more comfortable because of the motors, but if there is any wind on a dry day he has to bolt for home because his eyes get affected by the horse-dung, which constitutes the bulk of London street dust.

A lady had for years been noted as a horse asthma patient. Anybody who touched a horse's skin and then rubbed it on the skin of this patient would produce a great urticarial wheal, or if on the face would probably make the eyes bloodshot. Her serum given to a guinea-pig would passively sensitise it to horse serum 48 hours after; human serum and horse serum being, of course, in themselves quite innocuous to guinea-pigs. This same lady was out at a luncheon party one day and developed terrible asthma in the middle of the meal. Suspicion fell on some sausages, which by serological tests were proved to contain horse meat. An injection of horse serum given thoughtlessly on another occasion made her very ill, but relieved her horse asthma for four months.²

The ramifications of this strange illness are many. The danger of employing curative sera in such cases is obvious; not so obvious is the necessity for avoiding horsehair mattresses or horsehair upholstery.

occasion a cat strolled into the room where the King and this patient were talking. The latter clenched his hand and tried "to stick it out," but almost immediately incontinently bolted, and had to make his explanations later.

Similarly we have a sensitiveness to sheep, cows, pigs, rabbits, goats, and all the rest of them.

A man who has always hated the presence of rabbits or rabbit meat or rabbit skin. He is devoted to shooting, but always has to get the keepers to put him where there have not been rabbits about; otherwise he knows that he will not hit a bird.

Among these animal asthmas should be included a sensitiveness to the emanations from feathers of birds. This would seem at first sight more trivial than, say, a cat asthma, but is really much more important when it exists; a little tumbling about of pillows, bolsters, quilts, sofa cushions, and soft upholstery in general, will

DIAGRAM 7.—Here the extent to which the patient reacts to the pollen in question is denoted by the number of points to a star. The names of plants to the left of the diagram give the type of pollen employed for the particular reaction, and the initials along the top indicate the individuals upon whom these tests were carried out. The first six are hay fever sufferers, the two individuals to the right are relatives of hay fever sufferers and appear in Diagram 13, marked with an asterisk.

Cat and Other Animal Asthmas.

Parallel with horse asthma you have cat asthma, in which various substances from the cat (particles from the fur, the serum, the urine, &c.) provoke skin or eye reactions, like those shown for hay fever in Diagrams 2 and 3.

A patient who had some post at Court told me that he could not bear the presence of cats. They made him gasp for breath, so that he could not stay in the room with them, and would subsequently give him asthma. When you are in the presence of royalty, I understand, you are, so to speak, on parade: you must not go until dismissed. But on one

send the feather particles into the air. In the words of a patient, "You must put your head on the pillow as if on a wasps' nest." Even the swan's down powder puff may cause trouble.

We summed up hay fever, our type of a toxic idiopathy, under the three headings of Symptom-Complex, Specificity, and Heredity; now let us see how the animal asthmas correspond under these headings.

Symptoms.—As far as circumstances permit, these are identical both in local and constitutional effects. The experimental symptoms also correspond. The respective ophthalmo- and cutaneo-reactions are indistinguishable; an injection of an extract of curry-combings (or,

² Besche, of Christiania, in Berlin Klin. Woch., 1918.

as we have seen, of antidiphtheritic serum) causes the same symptoms as those which follow an over-bold dose of grass-pollen extract in the hay fever subject. Similarly, eating horse or rabbit produces much the same effect on those sensitive to that particular animal

Heredity.—In the hereditary nature of the diseases the animal asthmas correspond to our type, but as they are each of them much rarer than hay fever it is difficult to demonstrate many, say, of horse asthmatics in one family. On reviewing many family histories we

DIAGRAM 8.—Shows the typical response of a horse asthma patient to various members of the Equidae.

as the experimental ingestion of grass pollen by a hay fever subject.

Specificity.—Here, again, they correspond. The horse asthmatic is sensitive to horse substance and not necessarily to anything else. Each animal substance is sharply specific for its own type of asthmatic, but a patient may suffer from two or more animal asthmas at a time, just as the hay-fever patient may be sensitive

find good evidence of heredity, and also that different animal sensitivenesses tend to run in the same family (suggested here by Diagram 9, where a sister is sensitive to cat and a brother to horse).

It is quite clear, even from the few diagrams of heredity here published, that the animal asthmas tend to run in the same families as the hay fever cases; we have horse here in Diagrams 6 and 10, horse and cat in 9,

DIAGRAMS 9, 10, 11, 12, and 13.—As in Diagrams 5 and 6, a blackened male or female sign denotes a toxic idiopathy, while the nature of that idiopathy is denoted by the letters attached:—HF, Hay fever; H, Horse asthma; C, Cat asthma; G, Goat asthma; R, Rabbit asthma; B, Bacterial asthma; S, "Spasmodic" asthma; F, Food idiosyncrasy, and the number attached denotes the particular food which reacts: 1, Lobster; 2, Lobster, anchovy and duck egg; 3, Oysters; 4, Mackerel; 5, Honey; 6, Apples; 7, Chicken; 8, Oysters and lobsters; 9, Milk; 10, Onion; 11, Fish.

to other pollens—e.g., from ox-eye daisies or pæonies. Again, let us say the horse asthmatic may also have hay fever (this occurs in perhaps 40 per cent. of my cases), or he may be quite non-sensitive to pollen; or he may have hay fever early in life, grow out of it, and then develop some animal asthma later in life.

The different animal asthmas are separate or, at any rate, separable toxic idiopathies.

rabbit in 11, and goat in 12, all relating to, and half of them coinciding with, hay fever cases (besides coincidence with, and relation to, the toxic idiopathies to be mentioned next). We have seen that sensitiveness to any particular pollen other than grass tends to run in hay-fever tainted families; so that all our toxic idiopathies tend to be inherited together—there is a common taint.

BACTERIAL AND SPASMODIC ASTHMA.

From my first experience hay fever patients insisted on the occurrence of bronchial and spasmodic asthma in their families; but, to begin with, these complaints were discarded as having no possible connexion with a sensitiveness to pollen. After some time, however, I had to acknowledge that these diseases occurred with significant frequency. It is, again, necessary to work through very many family histories to reach full conviction, but Diagrams 9 to 13 show 11 cases of spasmodic asthma between them and 1 of bronchial asthma. Of these, the bronchial asthma and 4 cases of spasmodic asthma stand alone, though closely related to hay fever and other toxic idiopathies; 2 cases of spasmodic asthma coincide with hay fever, 1 with cat asthma, 1 with horse, and 2 with toxic idiopathies, to be described later.

For many years before the war we of the Inoculation Department of St. Mary's Hospital (and doubtless many others elsewhere) had been inoculating against bronchial asthma by immunising against the bacterial cause of the bronchitis, and frequently with strikingly successful results, and we were driven to the conclusion that the asthma was the remote effect of the bacterial infection. I believe now this asthma is a toxic idiopathy to the endotoxins of that particular microbe.

The specific ophthalmo- and cutaneo-reactions of the pollen-sensitive or animal-sensitive persons (Diagrams 2 and 3) are exactly paralleled by the ophthalmo- and cutaneo-reactions produced by the extracted endotoxins on the bronchial asthmatic,³ and such reactions are bacterially specific—e.g., a man infected with Pfeiffer's *B. influenzae* will react to that particular microbe on the scratched skin.

Again, just as violent asthma, cedema, and urticaria can be produced by injudicious injections of the specific irritants in hay fever and animal asthma subjects, so will the same symptoms be produced by too large an injection of the appropriate bacterial vaccine in a case of bronchial asthma, especially by the first dose or two of any series of inoculations.

It is important to note that for bacteria to produce asthma they need not be infecting the bronchi; they may, for instance, be infecting the gut wall—thus, perhaps, paralleling the effect of pollen in the food of a hay fever subject or the specific meat in the food of an animal asthmatic.

A bad case of asthma of several years' standing came to be treated by vaccines, but was refused because no infection of the bronchi could be found, and the case was apparently one of spasmodic asthma. At a second visit a history was obtained of chronic bowel infection, slight pain, and recurrent diarrhoea. A bacteriological examination showed an infection of pyocyaneus.⁴ A vaccine was used; the bowel disturbances stopped and the asthma symptoms promptly stopped also. (Personally communicated: Dr. John Matthews.)

This case suggests that bronchial asthma is a regional subdivision of bacterial asthma, and that spasmodic asthma had better be classed as asthma of unknown origin. It may be an undetected case of any one or more of the toxic idiopathies described or to be described here, but it may, no doubt, be due to some unsuspected air-borne irritant, such as the emanations or the spores from moulds—an idea which some cases suggest.

With an unknown irritant one cannot make experiments to prove specificity, but from the symptoms and, above all, from the heredity we must class spasmodic asthma as one of the toxic idiopathies; it remains to make it an asthma of known origin.

This was very much the stage the subject had reached before the war when the work had to be dropped. But in the United States of America much valuable work continued on bronchitis, hay fever, and, in particular, on food idiosyncrasies; these are frequently

grouped together under the name anaphylaxies.⁵ After the war I was anxious to see if my collections of hay fever and other toxic idiopathy cases suffered from any particular food idiosyncrasies. They did, giving quite surprising tales, of which a few examples will suffice to give the clinical picture and show that these disabilities are by no means trivial or "just fads and imagination."

"F_g."—The male ancestor in Diagram 9 was a remarkably healthy man, but apples always upset him. On his honeymoon his wife, after the manner of Eve, persuaded him to eat one; he spent the next 12 hours with violent vomiting and diarrhoea.

"HF F_g."—One of the grand-daughters in Diagram 13 could never since childhood tolerate a trace of honey. After many years' abstinence she took half a teaspoonful as an experiment. Within seven minutes she "came over all queer," and made her way as best she could to her bedroom, where she was found unconscious on the floor. She, too, spent the rest of the day with vomiting and diarrhoea. She gives the cutaneo-reaction as in Diagram 3, either with direct honey or with the trace of proteid precipitable from honey solution.

"F_g," the mother of the last example in Diagram 13, used to be sensitive to eggs, coming out in urticarial rashes whenever they were eaten. She has gradually accustomed herself to them, but remains sensitive to the rarer duck's egg. This is corroborated by a strong positive reaction with duck's egg proteid and no reaction with that of hen's egg.

"F_g," in Diagram 12, vomited so uncontrollably when put on cow's milk that, to save his life, he had to be given ass's milk. If he had chanced to be horse sensitive, Diagram 8 suggests that the change of dietary would have been jumping out of the frying pan into the fire.

A girl of 9 has all her life suffered from very bad "spasmodic asthma" accompanying the slight bronchitis which she occasionally had. A streptococcus vaccine was made, but gave little or no relief. A somewhat confused story of delicacy of digestion and tendency to dysentery (when one has had it all one's life one cannot describe nausea) led to skin reaction tests which disclosed a large number of sensitivenesses, amongst them to horse and to hen feather, but most pronounced of all were the reactions to the various flours; strongly to wheat and barley, and very strong to pea, bean, and lentil flour.

The symptoms fall into line with those of toxic idiopathies in general, closely resembling what we have seen to follow from pollen, horse meat, or a bacterial infection in the intestines of persons with those particular sensitivenesses. The constitutional troubles—depression, asthma, urticaria, &c.—follow along the same lines too, and one gets ophthalmo- and cutaneo-reactions precisely like those shown in Diagrams 2 and 3.

The specificity of the particular irritant for the patient and the patient for that particular irritant is as exact as with, say, hay fever or cat asthma.

Heredity is frequently found to the same food sensitiveness, but more often the food sensitivenesses vary in a family. Common inheritance, together with all the other toxic idiopathies, is seen from the diagrams where "F" denotes some food idiosyncrasy and the number following it denotes the particular food.

Before leaving these food idiosyncrasies some general considerations are worth while. They vary in intensity from a shock producing coma down to a hardly noticeable malaise, and when slight they are usually not detected. Frequently one gets without leading questions the history of "delicate digestion" or of being "faddy about food" from hay fever patients, which turn out to be quite well marked but unsuspected food idiosyncrasies. Another difficulty, both in the general diagnosis of a food idiosyncrasy and in specific diagnosis of the particular irritant, is that the reactions are frequently delayed, both in the natural disorder and in the diagnostic cutaneo-reaction; the delay may sometimes extend from, say, 10 minutes up to as long as 14 hours or longer (this delay also sometimes takes place with the bacterial cutaneo-reactions). So food idiosyncrasies often are unsuspected. Therefore in an anomalous case of dyspepsia it would be well to look for a family history of toxic idiopathies of any type. If the patient comes of a family so tainted, then the so-called dyspepsia may well chance to be a food idiosyncrasy.

³ One may get this bacterial cutaneo-reaction in cases of bacterial intoxication—e.g., a bad case of pyorrhoea—which do not have symptoms of asthma, urticaria, &c. It is believed that such symptoms would have been produced if the patient had had the toxic idiopathy taint, but may get rheumatism or gout instead if the diathesis happen to be in this direction.

⁴ This organism is frequently much more pathogenic than the text-books allow.

⁵ The use of this term would seem to be unfortunate, since the phenomena of the toxic idiopathies do not fall into line with those of anaphylaxis as demonstrable on a guinea-pig. "Anaphylaxis" has grown so protean nowadays as to cover almost any untoward biological reaction, and, therefore, when used so loosely, explains nothing.

Another point worth comment is that food idiosyncrasies are most frequent in childhood. From the day the child is weaned he is constantly meeting new proteid substances in the form of food; and, as a rule, children have an instinctive dislike to new foods or foods prepared in unrecognised ways. Possibly any new type of food requires an immunising effort on the part of the recipient to make that food wholesome, and any failure to so immunise would produce a food idiosyncrasy. Under the eye of a stern parent intent on seeing that the "children are not faddy" and that "good food is not wasted," the dislike and difficulty is soon got over with normal children.

One point of special interest is suggested by one of our examples given above; it must be well worth while to test the cutaneo-reactions of persistently vomiting babies for a milk sensitiveness. Some of the patent foods may work well in exceptional cases for this reason (a case of a child who could tolerate egg substitutes but not egg itself is instructive). In a thesis by L. De May for the University of Lyons 32 cases of uncontrollable vomiting and diarrhoea of infants were successfully treated by subcutaneous injections of cow's milk to produce "anti-anaphylaxis after the method of Besredka."

Worms.

Many other curious sensitivenesses to foreign proteids must apparently be included amongst the toxic idiopathies, but I must be brief. There is, for example, the fact that worms when handled or dissected for some time give all the nasal and eye symptoms of an air-borne toxic idiopathy; and occasionally one finds that children with intestinal worms, who happen also to be of the toxic idiopathy taint, apparently have asthma as a consequence and lose the asthma after the removal of the worms.

Insect Bites.

The bites and stings of animals are another occasion when small quantities of foreign proteid come into intimate contact with our tissues; and it does seem as if people of the toxic idiopathy taint sometimes give much stronger reactions to the bites of fleas or gnats than the normal person does. I am tempted to give a case in point.

Clewes, of Buffalo, U.S.A., who first introduced the use of a pollen vaccine for hay fever into America, told me when recounting his success that the most successful inoculation he had ever given was to a lady who had a house on the borders of Lake Erie. She was being inoculated at the time for hay fever, but was so sensitive to the bites of small gnats from the lake that one single bite, which would hardly have been felt by the normal individual, would cause such great swelling as to send her to bed for days. Clewes got a number of these gnats collected, brayed them in a mortar, and made a vaccine therefrom. After several inoculations the patient could lie out in a hammock at the edge of the lake and be bitten with pleasure.

This sounds a tall story, but she was hay-fever tainted, and if the bites and stings of insects can give rise to toxic idiopathies with people of the correct sensitiveness then it is quite understandable.

CONCLUSION.

I hope I have made it clear that all these apparently diverse affections are linked together in an extraordinary way by (1) their selectiveness; (2) by the symptom complexes; and (3) by heredity. This is worth doing for several reasons. First of all, the very fact of the connexion, and still more so the connecting link if only we could discover it, must have great significance in immunology; secondly, the detection of one definite toxic idiopathy in a patient should put us on the alert to discover others; and, lastly, anything we learn about one will help us in dealing with another toxic idiopathy. This refers chiefly to treatment, for what is sauce for the goose is likely to be sauce for the gander. Excluding all the palliatives, we have choice of two treatments for all of them—(1) avoiding the particular irritant, or (2) immunising against it.

I think it might be exaggeration to say that the study of these toxic idiopathies will open a new field of medicine, but I feel confident that they throw light from a new angle across a very large field of the old medicine.

The Croonian Lectures

ON THE

PSYCHOLOGY OF THE SPECIAL SENSES AND THEIR FUNCTIONAL DISORDERS.

Delivered before the Royal College of Physicians of London, June, 1920.

By ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

LECTURE II.*—PATHOGENESIS OF HYSTERICAL CUTANEOUS ANÆSTHESIA.
